A survey titled "A Survey of the Diagnosis and Management of (Central) Auditory Processing Disorders (APD)" was developed (see Survey section below) and mailed to 515 audiologist members of ASHAwho listed APD as an area of expertise. The web address of an online version of the survey was also provided in the printed material for participants who preferred electronic submission. In addition to the ASHA sample, the survey was distributed via e-mail to the Educational Audiology Association (EAA) e-mail list. The e-mail included a direct link to the electronic survey and instructions on how to obtain a paper copy, if preferred. Potential respondents were given 12 days to complete the survey. At the conclusion of the 12 days, another e-mail was released on the EAA e-mail list, extending the survey deadline an additional 5 days. None of the EAA participants requested a paper copy. EAA (2008) describes itself as "an international organization of Audiologists and related professionals who deliver a full spectrum of hearing services to all children, particularly those in educational settings." For this study, an assumption was made that educational audiologists would be more likely to be involved with pediatric APD testing and management than audiologists who worked in other specialty fields. Therefore, educational audiologists were included as part of the target population. EAA is composed of 1,000 members, and approximately 20% of those members are active on the e-mail list (EAA, personal communication, 2008), yielding approximately 200 potential recipients of the e-mail. It was impossible to estimate how many of these recipients were actually involved in APD testing and/or management; thus, the estimate of 200 is likely on the high end. Because the number of ASHA members who are also members of EAA and are active on the e-mail list is unknown, an exact number of distributed surveys cannot be determined; however, it can be estimated that a maximum of 715 surveys were distributed.

Survey

The survey was developed based on a review of two published APD surveys: Emanuel (2002) and Chermak et al. (2007). A number of similar questions were included in the current survey to directly compare the results of the current study with those of previous studies (e.g., demographic questions and questions regarding specific tests used). The majority of the questions were dissimilar so as to provide more extensive data on previously unexplored areas of practice, including how tests were selected and who provides APD intervention. The survey included six sections: pretesting, screening, test battery, specific tests, management, and demographics. The survey questions and a summary of the responses to each question are included in the enhanced online content associated with this article at http://aja.asha. org. The printed version of the survey consisted of 27 closed set questions and 10 "additional comments" boxes following pertinent questions. The online version consisted of 37 questions, because each comment box was required to have a separate number. Surveys received in the mail were entered into the Survey Monkey database, and all data were analyzed together.

The Towson University Institutional Review Board for the Protection of Human Subjects reviewed this study and classified it as exempt.

Results

A total of 195 responses were received; 75 responses were received via the online survey, and 120 surveys were received in the mail. Based on the number of surveys mailed (515) and the estimated maximum number of surveys distributed (715; see above), the response rate was estimated to be between 27% and 38%. Since only ASHA members received the paper survey, the response rate for ASHA was at least 23%; however, the exact

number could not be determined because ASHA members could also complete the survey electronically.
A summary of the data most relevant to the research questions is provided here. Note that not all respondents completed each question; thus, some of the percentages seen here and in the enhanced online content are based on a subset of respondents and not the total number of surveys.

Demographics

Most of the respondents were female (87%), and the highest earned degree was split almost equally between master's degrees (49%) and doctoral degrees (51%). The majority of respondents, together accounting for 82%, worked in schools, private practices, hospitals, or university clinics. The vast majority of respondents reported that they tested children from ages 7 to 17 years (>90% for age group categories 7-10, 11-14, and 14-17 years). In addition, a majority of respondents (63%) tested adults (18 and older). A smaller group of respondents (30%) reportedly tested children younger than 7.

Pretesting

Almost all of the respondents (n = 192, or 99%) indicated that they required basic audiometric evaluation prior to conducting APD testing. Of these respondents, the majority indicated they required pure-tone audiometry (100%), tympanometry (97%), speech recognition thresholds (92%), word recognition scores (WRS; 90%), acoustic reflex thresholds (69%), otoacoustic emissions (58%), andWRS in noise (54%). Relatively few required acoustic reflex decay (14%) and performance intensity functions (2%).

Respondents were asked whether they distributed questionnaires to the teacher and/or parent: 193 answered the question relative to the parent, and 190 answered relative to the teacher. Of these respondents, 75% and 65% indicated that a questionnaire was distributed to the parent or the teacher, respectively. Thus, the majority of the respondents were using questionnaires as part of their APD protocols. The most popular questionnaires used were Fisher's Auditory Problems Checklist (Fisher, 1976; 63%), the Children's Auditory Performance Scale (CHAPS; Smoski, Brunt, &Tannahil, 1998; 51%) and the Screening Instrument for Targeting Educational Risk (Anderson, 1989; 39%). Fewer than 20% chose any other specifically listed questionnaire; however, 31% selected "other" and specified that they used a sitegenerated questionnaire.

The respondents were asked to indicate other professionals from whom they "preferred" or "required" evaluations prior to diagnosis. The specific subspecialties selected were speech-language pathologist (SLP; n = 176, 90% of total survey sample), psychologist (n = 168, 86%), education specialist (n = 163, 84%), neurologist (n = 61, 31%), and otolaryngologist (n = 50, 26%). The majority of respondents who answered this question "required" a speech-language evaluation (46% preferred; 54% required); for all other professionals, the majority selected "preferred" as follows: psychologist (64% preferred; 36% required), education specialist (63% preferred; 37% required), neurologist (93% preferred; 7% required), and otolaryngologist (88% preferred; 12% required).

The majority of respondents (95%) indicated that they conducted a case history. Of these, most used either a case history form created on-site (60%) or an informal case history interview (59%). Very few (5%) reported using a published case history form.

Screening

The majority of the total respondents (98%) answered the questions regarding screening procedures, and about half (52%) reported that they did APD screening. The majority (69%) of respondents who screened for APD used the SCAN-A: Test for Auditory Processing Disorders in Adolescents and Adults (Keith, 1994) or SCAN-C: Test for Auditory Processing Disorders in Children-Revised (Keith, 2000b); 56% used questionnaires instead (or in addition). A third reported using classroom observation (33%), and 25% selected "other." The only common write-in response for this question was speech-in-noise testing, which was selected by nine respondents (9% of the respondents who answered this question). Very few other tests were selected from the listed items (11% dichotic digits [DD] and 5% Random Gap Detection Test [RGDT]; Keith, 2000a), and no other screening tools were listed by more than one person. Three respondents indicated that they used a speech-language

evaluation as part of the screening process, but there were no other mentions of multidisciplinary test result reviews by any participants.Note that the newest versions of the SCAN-A and SCAN-C-the SCAN-3:A and the SCAN-3:C (Keith, 2009a, 2009b), which include Gap Detection, Auditory Figure Ground, and Competing Words screening portions- were not available at the time this survey was conducted.

Test Battery

Respondents were asked whether they used an APD test battery; 97% (n = 181 of the 187 who answered the question) indicated they did. Respondents who answered yes were then asked what specific factors (i.e., case history and age) determined the test battery they used. The types of test batteries that were rated by respondents are listed in Table 1 along with the number of respondents who selected each rating. The number of respondents who rated each type of battery varied from 110 to 155. It is reasonable to assume that participants who provided an answer for some but not all categories most likely never used the items they did not rate; however, it is not possible to know for sure. Therefore, percentages for each response category within a row are reported based on the total number of respondents who rated each category (i.e., the total number of responses for each row). The highest rating (always, often, sometimes, or never) selected for each type of test battery is highlighted in bold in the table.

Examination of Table 1 indicates that the largest number of total responses (n = 155) occurred for "A set minimum battery for all patients with additions based on individual case history and age." Within this category, the majority of respondents (53%) indicated that they always used this approach, and 27% indicated that they often used this approach. Thus, most respondents (80%) had a set minimum battery that was quite flexible based on the individual patient. The smallest number of total responses (n = 110) occurred for "A set minimum battery for all patients with additions based just on individual case history." Within this type of response, the largest category of response was "never" (37%) followed by "sometimes" (28%). "Never" was also selected most often as the rating for the categories of "Battery completely based on case history considerations" and "Preset (C)APD [central auditory processing disorder] battery for all patients regardless of age or case history."

Respondents were asked how they selected their test battery, and 168 respondents provided answers (respondents could select more than one answer). Of these respondents, the majority selected their test battery based on clinical experience (57%). Other common responses included a review of literature (45%), ASHA technical reports (40%), seminars/ workshops on APD (36%), clinical site (31%), and Bruton Conference (Jerger &Musiek, 2000; 26%). The only fairly common write-in response was the BuffaloModel (Masters, Stecker, &Katz, 1998; 5%).

A total of 186 respondents indicated the average number of tests they administered during their test battery. The majority of these reported 4-6 tests (n = 108, 58%) followed by 6-9 tests (n = 52, 28%), 1-3 tests (n = 27, 15%), and 10+ tests (n = 9, 5%). Respondents were expected to select only one category; however, 10 respondents selected two.

Respondents were asked to indicate the frequency of use (always, often, sometimes, or never) for specifically named AP tests within common test categories. Table 2 lists the ratings for specific tests of dichotic listening, monaural lowredundancy speech, temporal processing, binaural interaction, and electrophysiology. There were 27 specifically named tests across these categories. The number of respondents who rated each test varied from 88 (MLR) to 179 (Staggered Spondaic Word test [SSW]; Katz, 1962), with a mean of 138 respondents. Table 2 shows the number of respondents who selected each rating for the specific test and the percentage of respondents (based on the number of respondents for the row). The most commonly occurring rating for each test is highlighted in bold. Note that all of the bold responses in Table 2 are either "always" or "never," indicating a somewhat polarized response for each test (although the largest response did not always indicate the majority of respondents). Note also that the tests in which the majority of respondents selected "always" generally had higher response rates than tests in which the majority selected "never." The nine tests in which "always" was the most common response had between 150 and 179 respondents (M = 158), and the 18 tests in which

"never" was the most common response had between 88 and 154 respondents (M = 128), suggesting, as mentioned previously, that some respondents skipped portions of the question rather than selecting "never." Although this cannot be assumed in the analysis, it is likely that the percentage of "never" responses for these tests was actually higher than these data indicated.

The tests most often rated as "always" were the SSW, DD, SCAN-A/SCAN-C, and Competing Sentences Test (CST; Willeford, 1978) in the dichotic category; the SCAN-A/ SCAN-C and Speech-In-Noise (SIN) Test (Etymotic Research, 1993) in the monaural low-redundancy speech category; and a pitch pattern test (PP; e.g., Pinheiro, 1977) in the temporal processing category. The most common rating was "never" for all of the listed binaural interaction and electrophysiology tests.

Figure 1 illustrates the number of respondents who indicated they "always" or "often" used the tests listed in the survey, in order from most to least. Percentages were not used for this overall comparison due to the variability in the number of respondents who answered each question. The most popular tests overall were the SSW, PP, SIN,DD(e.g.,Musiek, 1983), and the SCAN-A/SCAN-C.

Professional Issues in Diagnosing APD

The respondents were asked to indicate whether their ability to diagnose APD was limited by state law, school regulations, reimbursement, or other reasons. Respondents were allowed to select multiple responses. Sixty-eight respondents indicated one or more limitations. The most common limitations selected by these respondents included school regulations (41%), reimbursement (37%), time (10%), and test availability (9%).

The respondents were asked to indicate who was qualified to make a diagnosis of APD. The majority (97%) of the 190 respondents selected "audiologist." Other responses included SLP (16%), psychologist (7%), educator (5%), and otolaryngologist (3%). Some respondents (8%) indicated "other." The only fairly common write-in response was "multidisciplinary team" (6%).

Management

In the section of the survey titled "Management," respondents were asked a series of questions regarding common practices for follow-up for patients diagnosed with APD. Note that the terms management and treatment were used in the survey questions, and there was no mention of the term intervention. Differences in the meaning of these terms are addressed below in the Discussion section. The first question asked respondents to rate how frequently they used each of several types of APD "management recommendations" listed in the survey. These data are shown in Table 3. The largest number of respondents (51%) indicated they "always" used a customized list not based on a profile, and just over a third (38%) indicated they "often" used a list based on a diagnostic profile.

The next two questions in this section asked respondents to indicate who was responsible for recommending and who was responsible for providing APD "treatment plan/ management strategies," respectively. Note that respondents could select more than one person for these responsibilities. These data are shown in Figure 2, along with the data from the APD diagnostic question in the listed categories. Examination of Figure 2 reveals that the majority of respondents to the first question (81%) indicated that the audiologist was responsible for recommending an APD treatment plan/ management strategies, although over a third selected SLP (40%) and multidisciplinary team (36%). The majority of respondents who selected "multidisciplinary team" indicated that the team should include an audiologist, SLP, primary classroom teacher, education professional, school psychologist, and parents. In contrast, the majority of respondents indicated that the provision of treatment/management was considered to be the responsibility of the SLP (74%) and education professional (52%). Professionals selected by over a third of respondents included the classroom teacher (40%), audiologist (40%), and multidisciplinary education team (39%). Respondents indicated that the "multidisciplinary team" should consist of all the professionals listed previously, plus occupational therapists.

The next intervention question asked respondents, "If you provide recommendations for treatment for (C)APD, which of the following do you recommend?" The survey then included a checklist of specific recommendations

broken down into three categories: environmental modifications, remediation strategies, and compensatory strategies; the categories were completed by 187, 174, and 159 respondents, respectively, and these data are shown in Figure 3. All specifically listed items under the category of environmental modifications were selected by the majority of respondents including preferential seating (95%), gaining the student's attention prior to speaking (91%), repeating or rephrasing information (89%), personal FM systems (85%), preteaching new concepts or vocabulary (83%), sound-field FM systems (72%), modifying classroom activities (72%), and the use of a note taker (70%). About a quarter of the respondents (22%) selected "other"; common write-in responses included individualized recommendations based on the needs of the child.

Under the category of remediation strategies, the majority recommended Earobics (70%; www.earobics.com), auditory closure activities (70%), phoneme training (60%), and temporal training (51%). Slightly less than half of the respondents who answered this question recommended Fast ForWord (44%; www.scielearn.com) and prosody training (44%), and about a third recommended Lindamood-Bell training materials (37%; www.lindamoodbell.com). "Other" was selected by 21% of respondents, but no specific intervention strategy was selected by more than 5% of the overall respondents for this question. Note that the specifically listed remediation strategies were selected by fewer respondents than any of the environmental modification recommendations.

Under the category of compensatory strategies, the majority recommended active listening skills training (82%), metamemory skill training (73%), and context derived vocabulary building (52%). About half of the respondents recommended assertiveness training (47%), and about a third recommended discourse cohesion devices (39%) and cognitive behavior modification (34%).

Respondents were asked to indicate factors that limited their ability to provide treatment recommendations for APD. A total of 101 respondents indicated one or more limitations. The largest responses from this group indicated that they were limited by school district policy or procedures (46%) and lack of training (46%). About a quarter of the respondents indicated time (28%), individual school policies/procedures (26%), and reimbursement (19%).

Respondents were asked to indicate factors that limited their ability to provide direct treatment for APD. A total of 139 respondents provided one or more limitations. The largest responses were reimbursement (40%), lack of training (32%), school district policies (30%), time constraints (22%), and individual school policy (12%).

Comparison With Bruton Conference (Jerger &Musiek, 2000) Minimum Test Battery

The Bruton Conference (Jerger &Musiek, 2000) document was selected by 43 respondents in response to the question regarding how the test battery was selected. An analysis of the individual responses from these respondents indicated that only six respondents (14%) actually selected all of the test categories required to meet the minimum test battery recommendations listed in that document; in all other cases, electrophysiological tests were omitted.

The ASHA APD technical report (ASHA, 2005) and the AAA clinical practice guidelines for APD (AAA, 2010) recommend that audiologists use a test battery that is individualized and based on the patient's case history. The current data indicate that the vast majority (80%) of audiologists are following this recommendation by always or often selecting a test battery that is modified by age and case history.

Discussion

The current study included 195 completed surveys from a sample of audiologists who specified APD as a specialty area and/or were members of the EAA. This makes it the largest survey of current APD diagnosis and management practices available to date and the only survey that has been specifically targeted to audiologists who specialize in AP or who are likely to do so. It must be noted that there was no measure of expertise; these are self-reported experts. Therefore, this fact needs to be considered when interpreting the results.

The results indicate that the majority of respondents did the following: screened for APD; required audiologic testing prior to APD diagnostic testing; completed a case history for each individual; used questionnaires;

required speechlanguage pathology evaluations; and conducted dichotic, monaural low-redundancy speech, and temporal processing tests. The majority of respondents indicated that audiologists were responsible for diagnosing APD (97%) and for recommending treatment/management (71%), but providing treatment/ management was the responsibility of SLPs (74%) and educators (52%). Slightly less than half (40%) of the respondents indicated it was audiologists' responsibility to provide treatment/management.

Pretesting

The majority of the respondents asked the child's parent (75%) and/or the teacher (65%) to complete a questionnaire, with more than half of the respondents selecting the Fisher's checklist and the CHAPS. These data are similar to those reported by Emanuel (2002) in which 75% of the total sample reported using questionnaires, and the two most popular questionnaires were the Fisher's checklist and the CHAPS. These findings do not agree with the findings from Chermak et al. (2007); in that study, only two (12%) and four (24%) of the respondents indicated that they used the Fisher and the CHAPS checklists, respectively. However, in the Chermak et al. study, only 17 respondents answered the question, and the survey was not targeted to audiologists most likely to have an expertise in AP testing. In contrast, there were 53 respondents to this question in the Emanuel (2002) study and almost 200 in the current study. Thus, from both the current study and the Emanuel (2002) study, it appears that the use of questionnaires, especially the Fisher and the CHAPS, is fairly common.

In the current study, the purpose of the questionnaire was not thoroughly examined. Questions related to the use of questionnaires were included in the "pretesting" section of the survey; however, they may have been selected by respondents who used them for purposes other than screening. TheEmanuel (2002) study listed questionnaires in their own separate category, while in the Chermak et al. (2007) study, questionnaires were listed in a question along with behavioral and physiological tests. Thus, it is still unclear whether audiologists are using questionnaires for screening, diagnosis, or intervention. The AAA (2010) clinical practice guidelines state that questionnaires used for screening "generally have poor specificity, tend to over-refer, and have not been validated" (p. 13); however, respondents may be using them as part of the case history to develop an appropriate battery of tests for that individual, which would be appropriate under the new guidelines. Future studies should probe how audiologists are using questionnaires for AP patients.

The vast majority of respondents indicated that they would like to have evaluations completed by professionals in other disciplines prior to their AP diagnostic testing. The three most often selected specialty areas were speech-language pathology, psychology, and special education. The large number of respondents who would prefer not to diagnose without information from other specialties indicates that audiologists prefer not to work in a vacuum but instead want to be part of a larger, multidisciplinary (but not physician-based), diagnostic process for AP. These results are similar to those found by Emanuel (2002). In her study, 40%-50% of respondents indicated their "standard" evaluation (which was comparable to the "required" category in the current study of 36%-54%) included evaluations by SLPs, special educators, and psychologists, but very few required evaluations by physicians.

Test Battery

The vast majority (97%) of respondents indicated that they use a test battery approach when conducting APD testing. The reported test batteries most often consisted of four to six tests, which should meet the AAA (2010) task force's recommendation of approximately 1 hr for testing, depending on the tests that are selected and assuming the basic audiologic evaluation does not occur on the same day. The AP test battery is most often selected based on clinical experience and/or a review of the literature, which, in theory, means that audiologists are using best practices combined with good clinical judgment. Respondents most often reported that they "always" or "often" use a set minimum battery for all patients and make additions based on individual case history and age. Thus, they have a core group of tests that they give to each patient while still maintaining the flexibility necessary to individualize the assessment to the patient, a recommendation that was stated in the

most recent guidelines by both ASHA (2005) and AAA (2010).

More respondents indicated that they select their test battery based on ASHA technical reports (40%) rather than the Bruton Conference (Jerger &Musiek, 2000) proceedings (26%), and very few are actually following the complete Bruton Conference recommendations, because electrophysiology is not usually assessed. These findings were similar to the earlier findings reported by Emanuel (2002) in which none of the respondents followed the Bruton Conference recommendations, primarily because electrophysiological tests were omitted. Based on the current survey, it appears that audiologists are not relying on a recommended test battery; instead, two thirds of the respondents reported selecting their test battery using multiple sources, such as a combination of clinical experience, seminars on AP, and/or a review of literature.

The most often administered categories of tests were dichotic tests, monaural low-redundancy tests and temporal processing tests. Across all categories, the most popular tests were the SSW, PP, SIN, DD, SCAN-A/SCAN-C, CST, low pass filtered speech, and RGDT. Table 4 lists the findings from the current study and the findings from the four prior surveys for the tests specifically listed in the current study. The table is organized into the various categories of AP assessment (i.e., dichotic tests, monaural low-redundancy tests, temporal processing tests, binaural interaction tests, auditory electrophysiological tests, and a multiple-category test). The numbers highlighted in bold for each AP category represent the most popular tests-that is, those used by approximately 50% or more of the participants in the current study.

Examination of this table indicates that the highest ranked tests from the current study were also among the highest ranked tests for all of the prior surveys. Two exceptions to this pattern were for the PP and the RGDT. The PP was the highest ranked test (82%) in the current study as well as in the Emanuel (2002) study. However, this test was only used by 12% and 19% of the respondents in the Chermak et al. (2007) and Chermak et al. (1998) studies, respectively. In the current study, the RGDT was used by approximately 50% of the respondents, which is a substantial increase over the 6% reported in the Chermak et al. (2007) study. This finding is likely due to the fact that the RGDTwas relatively new at the time of the Chermak et al. (2007) study, and that survey was not specifically targeted to audiologists with self-professed expertise in APD.

The results in this table also reveal that relatively few participants (30% or fewer) used any of the binaural interaction tests or auditory electrophysiologicalmeasures as part of their APD assessment. This finding was evident in the current study as well for the data reported by the four earlier survey studies. The only exception to this was that Chermak et al. (1998) reported that 59% of their participants used ABR testing. It is unclear from their survey whether this percentage of respondents was using ABR for AP assessment or for other purposes.

The SCAN-A/SCAN-C test was one of the most popular AP tests in the current study. The popularity of this test was also demonstrated by survey data from Emanuel (2002) and Chermak et al. (1998). This test was originally published as a screening tool, and early versions of this test had been rated as inefficient at diagnosing APD (Chermak et al., 1998) and somewhat unreliable (Amos &Humes, 1998). Emanuel (2002) hypothesized that audiologists continued to use the SCAN-A/SCAN-C because the test material, which is professionally packaged and includes well-documented normative data and printed response forms, makes the test easy to administer and interpret. Recently, the SCAN-A/SCAN-C test has been substantially modified and is now known as the SCAN-3:A/SCAN-3:C (Keith, 2009a, 2009b). It now includes three screening tests (Gap Detection, Auditory Figure Ground, and CompetingWords), four diagnostic tests (Filtered Words, Auditory Figure Ground, Competing Words, and Competing Sentences), and two supplementary tests (Auditory Figure Ground and Time Compressed Sentences). Additional modifications, which have purportedly made the SCAN-3:A/SCAN-3:C much more psychometrically sound than previous versions, include (a) the normative data were collected on a very large sample (n = 775 including 525 children age 5.0-12.11 years); (b) the data were collected by 109 professionals (SLPs, audiologists, and psychologists) across a broad geographic region; (c) the sample represented appropriate gender, race/ethnicity, and socioeconomic statistics based on U.S. Census data; and (d) several validity and reliability studies were conducted which demonstrated that the test has good test-retest

reliability (.78 and .77 for SCAN-3:A and SCAN-3:C, respectively), high internal consistency (.93 and .91 for 3:A and 3:C, respectively), and high interscorer agreement (.98 for 3:A and 3:C; data cited in Andrews &Castilleja, 2007).

Lastly, the data in Table 4 suggest that a number of the tests in each of the three popular AP test categories are rarely used, as reflected by respondent rates ranging from 7% to 40%. This pattern is true for the results not only of the current study but also the earlier survey studies. Possible reasons for the low popularity of these tests include the following:

1. Many of these tests have multiple versions, and when clinicians order these tests from various manufacturers, there is a lack of data available regarding the appropriate normative data for each version.
2. Some clinics/audiologists develop their own normative data that may or may not reflect sound psychometric principles.
3. Information on how stimuli were created, what types of populations were sampled for developing norms, and how large these samples were is often not available to the clinician. These practices can lead to considerable confusion for the clinician regarding the appropriate use and interpretation of the test findings.

Management

Only four studies to date have focused on surveying clinical practices in AP testing, and these studies had little reportable data for APD management. Martin et al. (1998) stated that they asked one "subjective in nature" question on audiologic management, and the few audiologists who responded indicated that they generally referred AP patients elsewhere. Chermak et al. (1998) asked two questions. The first question asked where respondents would refer patients after AP diagnosis, and their results indicated primarily to an SLP (22%), another audiologist (17%), or a teacher (11%). The second question asked where respondents would refer patients if they suspected CANS problems, and their results indicated primarily an ENT (29%), neurologist (23%), or neuro-otologist (19%). Emanuel (2002) did not include any questions on management. Chermak et al. (2007) asked eight questions on intervention, but six of the questions were only answered by one respondent. The remaining two questions asked whether the respondent provided treatment/management to APD patients (94% of the 17 respondents said no) and how often particular specialists should conduct specifically listed treatment/management options (n = 17-25, depending on the treatment; see below for further discussion). Thus, one of the strengths of the current survey is that the information was obtained from a large sample on follow-up procedures following a diagnosis of AP.

In the current study, the vast majority of respondents (97%) indicated that audiologists should be the professionals to diagnose APD; a much smaller group (16%) indicated that SLPs were also qualified to diagnose APD. When the question shifted into treatment/management, a slightly larger number but still not a majority of respondents (40%) selected SLPs as responsible for recommending treatment/management, with the majority of respondents (81%) indicating that audiologists had this responsibility. When asked who was responsible for actually providing treatment/management, the response pattern shifted such that 40% selected audiologists, and the majority of respondents selected SLPs (74%) and educators (52%).

It is commonly reported that audiology began as a therapybased profession in the rehabilitation of soldiers returning fromWorldWar II with hearing loss. As the field has evolved, it has expanded into many areas of audiologic and balance diagnosis and treatment, with a large focus on the fitting of advanced technology. The focus on therapy appears to have become distinctly deemphasized in general audiologic practice. The current survey provides evidence for this shift in the area of AP. Specifically, many more respondents indicated that audiologists were responsible for diagnosis of APD than indicated that audiologists were responsible for providing treatment/management. The majority of respondents indicated that provision of ADP therapy/management was under the purview of SLPs and educators. With this said, 40% of the respondents did indicate that audiologists should be responsible for providing treatment/management, so it appears a sizable percentage of audiologists have not given up the AP therapy aspects of the profession.

In this survey, respondents were far less likely to recommend specific therapies for APD compared with non-therapybased recommendations such as environmental modifications and compensatory strategies. This is consistent with the findings of Chermak et al. (2007); in their study, the majority of respondents indicated that SLPs were responsible for providing therapy-based intervention (specifically, metalinguistic, metacognitive, and cognitive strategies; auditory training; and computer-based therapy tools); in contrast, the majority of their respondents indicated that audiologists were responsible for providing non-therapy-based management (specifically, assistive listening devices and environmental modifications).

In the current survey, all of the audiologists who responded to the questions regarding the various types of recommendation strategies selected multiple recommendation strategies, suggesting audiologists are providing patients with a number of options to address APD. The fact that more items were selected from the environmental strategies list (e.g., preferential seating or sound-field FM system) than from the remediation strategies or compensatory strategies lists suggests either a comfort level with these recommendations or, possibly, the view from some respondents that audiologists who are not providing treatment/management should not be prescribing specific therapy techniques that other professionals will use with patients. This is a common medical model, in which a recommendation is made for therapy, with specific strategies left to the expertise of the therapist. Since fewer than half of the respondents indicated that providing therapy/management was the responsibility of the audiologist, this response pattern is not unexpected. For the audiologists who did recommend remediation and compensatory strategies, the most commonly recommended were Earobics; skills training in the areas of auditory closure, phoneme and temporal training, active listening, and metamemory; and context derived vocabulary training. Some respondents commented that they did not have the time or training to provide APD treatment, while others indicated reimbursement was a deterrent.

Not only is audiology historically a therapy-based profession, an examination of the current scopes of practice for both AAA (2004) and ASHA (2004) indicates that audiologists are responsible for diagnosis and management of APD. Specifically, ASHA (2004, p. 6) states that the audiologist is responsible for the "evaluation and management of children and adults with auditory-related processing disorders," and AAA's scope of practice (2004, p. 3) states that "the audiologist is an integral part of the team within the school system that manages students with hearing impairments and students with auditory processing disorders." Although providing therapy is not specifically articulated, "management" may include all aspects of intervention including environmental modification, compensatory strategies, and remediation. Thus, the audiologist's involvement in the provision of services to children and adults diagnosed with APD may include all aspects of care. The finding that the majority of respondents felt the SLP was responsible for providing therapy/ management to APD patients may reflect the protocol at their facility or a number of factors limiting service provision. This is supported by the number of respondents who indicated that their ability to provide services was limited by reimbursement issues (40%), lack of training (32%), school district policies (30%), time constraints (22%), and individual school policies (12%).

The present survey found that most audiologists do not use either a published or a site-generated preprinted list of management recommendations; instead, themajority of respondents (75%) indicated they always or often create a customized list of management recommendations based on the findings of diagnostic tests. The majority (58%) indicated they always or often use a preprinted list based on diagnostic profile; however, the option of a customized list based on diagnostic profile was not included in this survey. Therefore, it is possible that audiologists use a profile diagnosis with an individualized list of recommendations and thus selected always/often for both categories. Optimally, recommendations should be developed specifically for each patient based on the deficits identified in the test battery (ASHA, 2005), and this is what the results suggest that the majority of audiologists are doing. With that said, just over a third of respondents always/often provide a preprinted list, which suggests a large number of audiologists do not provide individualized recommendations, unless their preprinted list includes a place for checkmarks to indicate which specific recommendations apply to

that particular patient, an option not specified on the questionnaire and thus not possible to determine from the data.

Note that in the survey reported here (created in 2007 and disseminated in 2008), the term management was selected as part of the title, as the heading for one section of the survey, and in many of the survey questions (similar to questions by Chermak et al., 2007, which was used as a model for the current survey). The term treatment was also included, but the term intervention was not used. When respondents were asked to indicate which recommendations they made for AP follow-up, the categories of environmental modifications (e.g., preferential seating and FM systems), remediation strategies (e.g., Fast ForWord and Earobics), and compensatory strategies (e.g., active listening skills training and cognitive behavior modification) were provided on the survey. According to AAA (2010, p. 6):

Intervention is an encompassing term referring to one or more actions taken in order to produce an effect and alter the course of a disease, disorder, or pathological condition. Treatment is any specific procedure used to prevent, remediate (i.e., cure), or ameliorate a disease, disorder, or pathological condition. Management refers to compensatory approaches (e.g., strategies, technologies) used to reduce the impact of deficits that are resistant to remediation.

Therefore, in future surveys, the term management should be replaced with intervention, and compensatory strategies should be replaced with management to follow more current terminology.

Summary

The results of this large-scale survey suggest several exciting trends regarding the diagnosis and management of APD. It appears that clinical audiologists who are self-reported experts in AP are taking a relatively consistent approach toward the diagnosis of APD. This approach includes screening for APD, requiring a complete audiologic test battery prior to administering behavioral AP tests, completing a thorough case history including both parental and teacher input for the pediatric population, and conducting a variety of behavioral AP tests that aim to assess different AP skills and different levels/regions of the peripheral auditory nervous system and CANS. Secondly, the audiologists who participated in this study reported that their APD assessment procedures often included input from multidisciplinary specialists including SLPs, psychologists, educational specialists, neurologists, and otolaryngologists. The input from this team of professionals as well as input from a child's parents are integral to planning appropriate management/intervention strategies for the individual and his or her family.

In the past decade, the field has seen considerable progress in the development of more rigorous and psychometrically sound behavioral AP test materials, such as the RGDT (e.g., Muluk, Yalcinkaya, &Keith, in press; Yalcinkaya, Muluk, Atas, &Keith, 2009), the Gaps-In-Noise test (e.g., Musiek et al., 2005; Shinn, Chermak, &Musiek, 2009; Weihing, Musiek, &Shinn, 2007), and the SCAN-3:A/SCAN-3:C (e.g., Andrews &Castilleja, 2007). Published data have been made available regarding how the stimuli were developed for these tests, how normative data were collected, and who is an appropriate age group and/or clinical population for this type of testing. Continued advancement with this type of in-depth information is needed to ensure that AP tests are applied to appropriate populations and yield information that is reliable and valid.

The results of the current study suggest that the majority of audiologists involved in AP testing believe diagnosing APD and making recommendations for treatment/management are the responsibility of the audiologist. In contrast, the majority of respondents indicated that provision of therapy/ management is the responsibility of SLPs and educational specialists. With that said, 40% of the respondents indicated audiologists are responsible for providing therapy/management; therefore, a fairly sizable number of audiologists still feel audiologists should be providing therapy/management. Many of the audiologists in the current study indicated that their ability to provide therapy/management is restricted by reimbursement issues and inadequate training. If APD therapy is to remain within the scope of practice for audiologists, university program directors should improve APD therapy training, and audiology professional associations should advocate for improved

reimbursement of APD therapy. To improve training for audiologists who are currently practicing, hands-on AP therapy should be a focus of national and statewide professional conferences and intensive seminars. In addition, audiologists need to continue toworkwith colleagues in hearing science, cognitive neuroscience, and neurobiology, as these professions continue to learn how the brain processes both verbal and nonverbal stimuli at different levels and regions of the CANS. Multidisciplinary neuroscience must continually be considered and, if appropriate, incorporated into the development of improved screening and diagnostic tests for assessing AP skills as well as intervention strategies to address APD.

Abstract: To summarize the literature on patterns and risks of personal listening device (PLD) use, which is ubiquitous among teenagers and young adults. The review emphasizes risk awareness, health concerns of PLD users, inclination to take actions to prevent hearing loss from exposure to loud music, and specific instructional messages that are likely to motivate such preventive actions. We conducted a systematic, critical review of the English-language scholarly literature on the topic of PLDs and their potential effects on human hearing. We used popular database search engines to locate relevant professional journals, books, recent conference papers, and other reference sources. Adolescents and young adults appear to have somewhat different perspectives on risks to hearing posed by PLD use. Messages designed to suggest actions they might take in avoiding or reducing these risks, therefore, need to be targeted to achieve optimal outcomes. We offer specific recommendations regarding the framing and content of educational messages that are most likely to be effective in reducing the potentially harmful effects of loud music on hearing in these populations, and we note future research needs.

Purpose: To summarize the literature on patterns and risks of personal listening device (PLD) use, which is ubiquitous among teenagers and young adults. The review emphasizes risk awareness, health concerns of PLD users, inclination to take actions to prevent hearing loss from exposure to loud music, and specific instructional messages that are likely to motivate such preventive actions.
Method: We conducted a systematic, critical review of the English-language scholarly literature on the topic of PLDs and their potential effects on human hearing. We used popular database search engines to locate relevant professional journals, books, recent conference papers, and other reference sources.
Conclusions: Adolescents and young adults appear to have somewhat different perspectives on risks to hearing

posed by PLD use. Messages designed to suggest actions they might take in avoiding or reducing these risks, therefore, need to be targeted to achieve optimal outcomes. We offer specific recommendations regarding the framing and content of educational messages that are most likely to be effective in reducing the potentially harmful effects of loud music on hearing in these populations, and we note future research needs.

Key Words: hearing health messages, MP3 players, noise-induced hearing loss, personal listening devices

It is well established that permanent noise-induced hearing loss (NIHL) can result from exposure to any sound that is sufficient in intensity and duration. The damage is typically to the inner ear and, although somewhat dependent on the susceptibility of individual ears, is largely preventable (Clarke &Bohne, 1999). In fact, exposure to excessive levels of noise is the leading preventable cause of sensorineural hearing loss (Rabinowitz, 2010).

In recent years, recreational activities have gained attention as a leading cause of NIHL, and personal listening devices (PLDs), which are used primarily for the reproduction of music, have been the focus of intensive research. Although the public generally associates sensorineural hearing loss with aging, this problem may now be affecting younger generations due to exposure to various recreational activities, including PLD use. A recent study (Shargorodsky, Curhan, Curhan, &Eavey, 2010), in which 1988-1994 data from The Third National Health and Nutrition Examination Survey (NHANES III) and 2005-2006 data from the NHANES were compared, concluded that the prevalence of hearing loss among U.S. adolescents ages 12-19 years increased from 14.9% in 1988-1994 to 19.5% in 2005-2006. Although the increased hearing loss observed in the 2005-2006 cohort was typically unilateral and only slight or mild in degree, it was high-frequency in nature and statistically significant. Following a similar analysis of the same prevalence data, using comparable inclusionary criteria but slightly different definitions of pure-tone average, Henderson, Testa, and Hartnick (2011) found no indication of an increase in overall noise-induced threshold shifts (NITSs) in the 2005-2006 cohort when compared with the 1988-1994 cohort. Female youths, however, when compared with their male counterparts, were similarly exposed to recreational noise, were less prone to use hearing protection, and showed an increased prevalence of NITSs. Shargorodsky et al. (2010) and Henderson et al. (2011) conjectured that loud music may be a possible contributing factor for the increased prevalence. They noted that despite a greater awareness of music-induced hearing loss in recent years, adolescents and young adults tend to underestimate the warning symptoms of hearing loss following exposure to loud music and to exhibit a relative lack of concern for such symptoms.

Despite data such as these, it must be acknowledged that researchers hold divergent views about the extent to which the prevalence of hearing loss and changes in hearing sensitivity-and specifically changes in NIHL-have occurred over the past several decades. Except in cases in which there were substantial asymmetries in the threshold data, the audiometric data analyzed in the two studies mentioned above generally were not subjected to a retest, thus making it impossible to determine whether the observed threshold shifts were temporary or permanent. Schlauch and Carney (2011) employed computer simulations to estimate false-positive rates for protocols that use notched audiograms to signify NIHL; the authors argue that the NHANES III data for children ages 6-11 years are consistent with their simulations and suggest no significant NIHL in this young subgroup. They also found that pass-fail data suggested by expert clinicians, when applied to the NHANES III data, yielded unacceptably high false-positive rates. They speculated that earphone reference levels, audiometric variability at 6 kHz, failure to repeat and average threshold measurements, and the identification of unilateral hearing loss as associated with NIHL are methodological problems that may lead to high false-positive rates. The presence of disease entities, the technological sophistication of test equipment, advances in medical and surgical treatments for conductive hearing loss, and the effectiveness of hearing conservation programs are all factors, singly or in combination, that may affect prevalence data across generations (Hoffman, Dobie, Ko, Themann, &Murphy, 2010). Unfortunately, these factors limit our ability to draw definitive conclusions about changes in the prevalence of hearing loss from such comparisons.

Before PLD use can be clearly linked to an increased incidence of NIHL, many issues remain to be resolved. A reasonable position to take on this controversial subject is that expressed by Fligor (2009a), who indicated that while most peer-reviewed studies have revealed that the average PLD user is not at risk for NIHL, one should not ignore the needs of the others who are at risk. Today, there is a continuing concern that the ubiquitous nature of PLDs may increase the risk to hearing, as evidenced by reports in the current literature and the popular media. Although not necessarily a precipitating factor, the fact that PLDs are highly portable and currently capable of storing up to 40,000 songs and playing for up to 36 hr on a fully charged battery serves as a predisposing condition to reinforce this concern. For those who are at risk, audiologists and other professionals need to convey messages about hearing health risks and self-protective behaviors as well as to conduct research on the appropriateness of targeted messages aimed at preventing or reducing any deleterious effects of PLDs on hearing.

The goal of this article was to provide a comprehensive review of literature that addresses a risk issue which has reemerged due primarily to the patterns of use of PLDs and attitudes expressed by young people that they are invulnerable to hearing loss from such use. To this end, we conducted a systematic review of the English-language scholarly literature on the potential risks to hearing posed by the use of PLDs. Coverage included the primary peer-reviewed literature, as well as books and book chapters, recent conference papers, online journals, technical reports, and standards. The latter materials were reviewed because of their potential supplementary value in providing a framework for understanding the current public and professional discourse surrounding this controversial topic. Our search method involved the use of popular database search engines, including Academic OneFile, CINAHL Plus, Google, Google Scholar, MEDLINE (on FirstSearch), OmniFile Full Text Select, and ProQuest. References in the included studies were manually searched for additional resources. Relevant search terms were used to locate materials associated with damage risk criteria, patterns of PLD use in young adults and adolescents, and the effect of different earphone types on output levels and preferred listening levels. Also, we searched for materials that provided a theoretical framework as to why some young people engage in risky behavior, as well as recommendations regarding specific messages that might be communicated to them to raise their awareness of the risks of hearing loss from PLD use and to motivate them to take precautions that effectively reduce those risks. The above topics compose the major sections of our review.

Our knowledge of PLD usage and the extent to which it raises the risk of hearing loss has been derived from a combination of survey and experimental research. Surveys have typically provided information about patterns of use, risk awareness, degree of concern about consequences, and types of behaviors in which individuals are willing to engage to avoid or lower hearing health risks. Experimental studies have typically provided information regarding the actual output levels of PLDs, listening levels that young adults prefer under real-world conditions, and whether or not these levels are capable of inflicting hearing impairment. Reflecting the technological changes over the past several decades, experimental investigations have been conducted on the auditory effects of exposure to loud music, played through earphones, using stereo receivers (MacLean, Stuart, &Stenstrom, 1992;Wood &Lipscomb, 1972), portable radios and personal cassette players (Bradley, Fortnum,&Coles, 1987; Catalano&Levin, 1985; Hellström, 1991; Hellström &Axelsson, 1988; Katz, Gerstman, Sanderson,&Buchanan, 1982;Meyer-Bisch, 1996; Pugsley, Stuart, Kalinowski, &Armson, 1993; Rice, Rossi, &Olina, 1987; Turunen-Rise, Flottorp, &Tvete, 1991; Wong, Van Hasselt, Tang, &Yiu, 1990), compact discs (Fligor &Cox, 2004), and more recently, MP3 players (Atienza et al., 2007, 2008; Danhauer et al., 2009; Farina, 2007; Fligor &Ives, 2006; Hammershøi, 2007; Hodgetts, Rieger, &Szarko, 2007; Hoover &Krishnamurti, 2010; Keith, Michaud, &Chiu, 2008; Kumar, Mathew, Alexander, &Kiran, 2009; McNeill, Keith, Feder, Konkle, &Michaud, 2010; Peng, Tao, &Huang, 2007; Portnuff &Fligor, 2006; Punch et al., 2009; Rabinowitz, 2010; Shah, Gopal, Reis, &Novak, 2009; Snowden &Zapala, 2010; Torre, 2008; Vogel, Brug, Hosli, van der Ploeg, &Raat, 2008; Vogel, Brug, van der Ploeg, &Raat, 2007; Vogel, Verschuure, van der Ploeg, Brug, &Raat, 2009;

Williams, 2005; Zogby International, 2006a, 2006b). The literature does not provide a consensus view regarding a causative relationship between PLD use and hearing loss, although many investigators have concluded that PLDs, especially as used by many teenagers and young adults, present a substantial risk of hearing loss or are a probable contributing factor to hearing loss over the lifespan. Representative survey and experimental studies reported in the peer-reviewed literature on the relationship between the use of PLDs and hearing loss are summarized in Table 1.

Damage Risk Criteria: What Levels and Durations Are Unsafe?

Our knowledge of vulnerability to NIHL comes largely from reports of associations between measured levels of various occupational noises and audiometric hearing loss. Decades of research have revealed that both the level and duration of noise are the two major determinants of hearing impairment. Together, these elements form the basis for damage risk criteria. Measures of exposure levels have traditionally used the dBA scale of sound level meters. This scale is intended to filter, or exclude, lower frequencies to which the ear is relatively insensitive. The National Institute for Occupational Safety and Health (NIOSH) has established the criteria most often used today to predict the damage resulting from exposure to various levels of occupational noise, and these criteria are commonly used to assess the level of risk from exposure to many types of environmental noise, including music from PLDs. NIOSH (1998) specifies recommended exposure limits that allow an individual to be exposed continuously to an 85-dBA noise source over an 8-hr period before that source is considered to be a significant contributor to NIHL. Such a noise or an equivalent-level intermittent noise-expressed as a time-weighted average and measured in equivalent continuous sound level (Leq) in decibels over an 8-hr period-is regarded as a 100% dose. A 3-dB timeintensity trading relationship is assumed, such that a noise level of 88 (85 + 3) dBA is allowable for 4 hr, 91 (88 + 3) dBA is allowable for 2 hr, and so on. As applied to PLD listening, once a given output level of music is known, the following formula can be used to calculate the exposure time at which a 100% dose is reached:

T = 8/2^sup (L - 85)/3^

(where T is the exposure time, in hours, to reach 100% dose, and L is the measured output level in dBA). Exposures beyond a 100% dose are considered likely to induce hearing loss.

A notable number of researchers have attempted to determine the maximum PLD volume settings or output listening levels that are safe, based on the above or a derivative formula. Because the reference microphone for quantifying the degree of risk from occupational noise has typically been placed at ear level, with the listener absent, a sound-field equivalent correction factor should be made to output levels of PLD earphones to reflect the fact that these measurements are often made near the eardrum, either in the listener's ear canal or in an artificial ear or acoustic manikin, as opposed to outside the head (Fligor, 2009b; Hammershøi, 2007; Keith et al., 2008; Shotland, 1996). These corrections should also be assumed to differ slightly for different earphone types (MacLean et al., 1992). In general, the research to date has underutilized these sound-field equivalent corrections, with the net result being that the literature falls somewhat short in providing definitive information on damage risk from PLD use.1

Portnuff and Fligor (2006) determined damage risk using five MP3 players from three manufacturers and expressed their measurements in sound-field equivalent levels. They incorporated stock (earbud) earphones and four additional models of earphones with each player, and measured across five popular music genres. For maximum volume settings, they found periods of up to only 18 min/day to be safe. Regardless of earphone type, no limit was recommended at volume control settings below 60%; at 60%, no limit was recommended for earbuds or supra-aural earphones. At higher volume settings, specific limits ranged from 3 min to 20 hr, depending on earphone type. They found no significant differences across genres of music.

Hodgetts et al. (2007) found that maximum output levels of the MP3 player they studied could be used for only 1-15 min/day with earbuds and supra-aural earphones. Ninety percent of college students in Torre's (2008) study indicated that they used their PLDs at medium or loud volume settings, which corresponded to sound

pressure levels of 72 and 88 dB, respectively. At self-identified typical and worst-case volume settings whose sound levels were established experimentally, and at self-reported duration of daily use, none of the university students in a study by McNeill et al. (2010) exceeded the NIOSH (1998) damage risk level of 85 dBA (Leq8). Nineteen of the 28 students, however, reported at least one symptom of possible NIHL, with tinnitus reported by 10 students. Atienza et al. (2007, 2008) determined output levels produced by an Apple iPod Nano at various volume settings, concluding that users could safely listen at their preferred levels with supra-aural earphones or earbuds at full volume for slightly over 1 hr/day. Fligor (2009b) suggested a rule of thumb that limits the volume control of earbuds to 80% of maximum if the listening time is 90 min or less per day. He notes, in addition, the difficulty of linking qualitative descriptors, such as those used in surveys, to specific output levels.

Relatively few studies have included actual measurements of hearing sensitivity in PLD users. Ahmed and colleagues (2007) studied 24 college students whose patterns of PLD use were judged to be potentially hazardous only for a minority; there was no audiometric indication (through 14000 Hz) of early hearing loss in any of the students. Shah et al. (2009), in a study of PLD use, conducted pure-tone screening on 94 undergraduate students, graduate students, and faculty and staff. Hearing loss was found in only a small percentage of their sample, mostly in the faculty and staff. Hearing sensitivity, however, was not associated with the number of PLDs used, amount of time of PLD use, or hearing-related symptoms. An earlier study by Meyer-Bisch (1996) found that two thirds of 1,364 individuals who were regularly exposed to loud music from cassette players, rock concerts, and discotheques exhibited worsened high-frequency pure-tone hearing thresholds. That is, there was a small but statistically significant elevation of thresholds in individuals whose exposures to loud music were greater than 7 hr weekly, compared to those who were exposed for 2-7 hr weekly. Kumar et al. (2009) found normal audiometric thresholds in 70 adults who had used PLDs for over 2 years, as well as in 30 nonusers of PLDs. They also found, however, a positive correlation between hearing thresholds and music levels and a negative correlation between music levels and distortion product otoacoustic emission (DPOAE) amplitudes and signal-to-noise ratios, leading them to conclude that listening to music through PLDs at higher intensities may cause subtle preclinical damage to the auditory system that could result in permanent hearing loss later in life. It is important to note that Lapsley Miller, Marshall, Heller, and Hughes (2006) reported that DPOAE amplitudes were more sensitive to NIHL than pure-tone hearing thresholds.

Peng et al. (2007) conducted conventional and extended high-frequency audiometry (10-20 kHz) on two groups: 120 college students who were users of PLDs and 30 normal hearing young adults who were nonusers. They found hearing thresholds in the 3000-8000-Hz frequency range to be significantly increased (>25 dB HL) in the PLD listeners, detecting impaired hearing in 14% of the 240 ears studied. Results of these latter two studies suggest that high-frequency audiometry may be a good early indicator of cochlear hearing loss due to noise exposure.

Patterns of PLD Use in Young Adults and Adolescents

In this section, we explore PLD use patterns and how they differ for young adults and adolescents. We give special attention to risk awareness, hearing health concerns, and susceptibility to behavioral changes that reduce risks to hearing, as these factors are especially pertinent to the development and dissemination of health-related messages.

Young Adults

For years, college students have represented a major consumer group in which the downloading of MP3 music and the use of MP3 players are widely popular. As early as 2000, Latonero reported that 69% of college students were downloading MP3 music, and a recent study (Danhauer et al., 2009) reported that almost 94% of college students owned a PLD capable of downloading music. In developed countries, PLD use appears to be a global phenomenon. In a study of 1,512 Dutch adolescents (Vogel et al., 2009), for example, 90% reported listening to PLDs through earphones.

Hoover and Krishnamurti (2010), in a survey of college students who were frequent users of MP3 players, found

that two thirds used their device for 3 or more days/week, more than three fourths used their MP3 player for 2 hr/day or less, and about half listened at 50% of the maximum volume setting or less. Users reported walking or commuting on campus as the most frequent daily activities associated with PLD use, noting that they listened at increased volume settings when necessary to overcome background noise. Exercising was reported as the most frequent weekly activity associated with PLD use. About a third of the college students who frequently used MP3 players reported occasionally using them at maximum volume settings. The authors expressed concerns regarding college students' occasional use of MP3 players at full volume and their reduced environmental awareness.

In another study of college students (Punch et al., 2009), 83% reported using an MP3 device for listening to music, mostly with earbuds or supra-aural (over-the-ear) headphones. More than 75% of users reported using their devices daily or several times per week, with roughly half reporting daily use. About two thirds of MP3 users indicated that they listened to the device for 1 hr or more per day. Over half reported that they sometimes or often used their MP3 device to block background noise (58%) and that they were somewhat or very concerned about losing their hearing from PLD use (55%). Generalizing from their sample, the researchers estimated that about 6% of college students listened to MP3 players at volume settings sufficiently high to put them at risk for hearing loss. Fligor (2007) indicated that this percentage ranged from 5% to 15%, depending on the listening environment, with higher volume levels being common in noisy surroundings. Torre (2008) found that over 90% of the college student participants in his survey used a PLD, with almost 90% reporting listening at either a medium or loud volume setting and over 50% reporting listening between 1 and 3 hr/day. McNeill et al. (2010) reported, in a small sample of college students, the median frequency and duration of use to be 6.5 days/week at 2 hr/day.

In a cross-sectional convenience sample of 94 adults (18 to 65 years old) at a university recreation center (Shah et al., 2009), the majority expressed concern about hearing loss (85%) and were willing to protect their hearing by using lower volume settings (77%), and more than half mistakenly felt that NIHL is a medically reversible condition. Many (40%) expressed a desire for their family physician to be more concerned about their hearing, a finding supported by other studies (Chung, Des Roches, Meunier, &Eavey, 2005; Quintanilla-Dieck, Artunduaga, &Eavey, 2009).

Adolescents

The downloading of digital music has become increasingly popular among younger groups. Snowden and Zapala (2010) found that the majority of middle schoolers they surveyed listened to their iPods at unsafe levels. They described middle schoolers as inaccurate judges of the intensity of their selected PLD volume levels, prone to risking NIHL, and failing to see their behavior as risky. Although teenagers (Zogby International, 2006b) and college students (Snowden &Zapala, 2010) reported similar degrees of willingness to reduce their volume settings and listening time, the college students indicated a greater willingness to purchase special earphones, in an effort to protect their hearing, than the teens. The adults in the Zogby International (2006b) study indicated that they were less likely than the teens or the college students to take any preventive actions.

Vogel et al. (2008) obtained qualitative information from focus group discussions of adolescents age 12 to 18 years who were enrolled in prevocational and pre-university education programs. Although these students appeared to be generally aware of the risks of hearing loss from exposure to loud music, they expressed low personal vulnerability to musicinduced hearing loss and a low likelihood that they would take protective precautions. Most adolescents in that study, especially the male students and students from prevocational schools, indicated that they often played their MP3 players at maximum volume, expressed a low personal vulnerability to music-induced hearing loss, and demonstrated poor receptivity to any interference with their music-listening habits. The authors recommended that interventions should target students from prevocational schools and focus on increasing adolescents' knowledge of the risks of loud music and how to protect themselves. Their findings are consistent with the observation that some adolescents do not think consciously

about their MP3-related listening behavior and are likely, left to themselves, to engage in risky listening behaviors and are unlikely to seek protection (Kasper, 2006).

The existence of gender, race, and ethnicity differences in patterns of PLD usage has not been explored extensively, but preliminary data suggest directions in which to aim health communication messages. In adolescents (ages 12-19 years), girls have been found to listen to MP3 music more often than boys, but boys listened at louder levels, making both genders vulnerable to hearing loss (Vogel et al., 2009). Vogel et al. (2007) identified young people who are male and/or of lower economic status or education level as target groups at which hearing loss prevention messages should be aimed. Their findings are consistent with the survey results reported by Shargorodsky et al. (2010). The latter researchers found the prevalence of hearing loss not to differ significantly by age, race, or ethnicity in either the 1988-1994 or 2005-2006 surveys, described earlier.

In their study of middle schoolers, Snowden and Zapala (2010) reported that some students practiced monaural earbud use and sharing an earbud with a friend. The authors suggested that this practice may result in monaural volume levels that exceed those in either ear when listening binaurally, thus increasing the potential for hearing damage. They, along with Vogel et al. (2008), recommended that manufacturers of PLDs should limit the output of their units in future models. That strategy has already been adopted in France, where the maximum output is limited to 100 dB SPL (Dance &Wash, 2008). Snowden and Zapala noted that PLDs could be made safer by developing applications using visual indications of safe and unsafe volume levels and that such applications should be accompanied by education.

Based on a total of 2,500 completed MTV.com survey questionnaires (Quintanilla-Dieck et al., 2009), hearing loss was found to be considered a problem by 32% of respondents, even though nearly half admitted experiencing symptoms such as tinnitus or hearing loss after loud music exposure. Most respondents reported that they learned about prevention of hearing loss mainly through the popular media, indicating that they would adopt ear-protective behavior if urged to do so by health care professionals.

Effects of Earphone Types

Currently, three types of earphones-earbuds, supraaural, and inserts-are widely available commercially. Over half (50%-92%) of PLD users report using conventional stock or extended-range earbuds (Danhauer et al., 2009; Hodgetts et al., 2007; Hoover &Krishnamurti, 2010; Punch et al., 2009).Different earphone styles are known to produce different output levels at the same volume settings (Atienza et al., 2007, 2008; Fligor &Cox, 2004; Fligor &Ives, 2006; Hodgetts et al., 2007; Portnuff &Fligor, 2006). Measured output levels of earbuds are capable of producing 5-6-dB higher levels than supra-aural earphones (Portnuff &Fligor, 2006), and insert earphones are typically capable of producing higher levels than either supra-aural earphones or earbuds (Atienza et al., 2007, 2008; Keith et al., 2008; Rabinowitz, 2010). Fligor and Ives (2006) have stated that preferred listening levels for different styles of earphones should not be expected to be different for the different styles. Hodgetts et al. (2007), however, found preferred listening levels under noisy conditions to be higher with earbuds than with supra-aural earphones, and Atienza and colleagues (2007, 2008) found the opposite. In the latter study, the mean preferred output level was highest for supra-aural earphones, next highest for earbuds, and lowest for insert earphones under quiet, lownoise, and high-noise conditions. Under the high-noise condition, insert earphones were preferred at a 7-dB lower level than with earbuds and at a 12-dB lower level than with supra-aural earphones. These differences in output capabilities very likely reflect differences in the degree to which the different styles occlude the ear canal. This explanation is consistent with the observation that insert earphones have the highest noise-attenuating characteristics, supra-aural earphones have the least, and earbuds have intermediate noiseattenuating properties. Users of PLDs tend to raise the volume setting as background conditions become more distracting (Airo, Pekkarinen, &Olkinuora, 1996; Atienza et al., 2007, 2008; Danhauer et al., 2009; Hodgetts et al., 2007). Because listeners tend to use them at lower output levels, insert earphones offer the safest option, especially in situations in which awareness of environmental noise and hearing or understanding conversations are not critical.

A few investigators have measured the maximum output of PLDs. Keith et al. (2008) measured maximum output levels of nine different models of PLDs and 20 earphones of various types, and found them to range from 101 to 107 dB SPL. Portnuff and Fligor (2006) found maximum levels to range from 96 to 105 dBA. Atienza et al. (2007, 2008) measured levels at the eardrum, using an acoustic manikin, showing maximum levels ranging from approximately 90 to 98 dBA across supra-aural, earbud, and insert earphones. These levels are above those capable of inducing hearing loss when used for prolonged periods, as explained above.

Unfortunately, earphones designed to reduce background noise through active noise cancellation have been found to result in preferred output levels in noisy background conditions that are only slightly lower than with traditional earphones (Hodgetts et al., 2007). Fligor and Meinke (2009) have reported that roughly 5% to 10% of users listen at high levels, regardless of background noise, concluding that the use of noise-canceling or sound-isolating earphones will not necessarily reduce the risk to hearing. Adolescents are prone not to use noise-limiting earphones (Vogel et al., 2009).

Framework for Health Risk Messages

A compelling theoretical framework for developing and communicating messages as part of public information campaigns to prevent hearing loss from PLD use is the Protection Motivation Theory (PMT; Rogers, 1983; Rogers &Prentice- Dunn, 1997). PMT is one of several theories proposed to understand how people choose to behave when faced with various threats, including threats to health. An underlying assumption of these theories is that if people can be motivated to perform adaptive behaviors over maladaptive ones, risk conditions can be identified and prevented. As with other such theories, PMT is based on the idea that motivation toward protection results from a perceived threat and a desire to avoid a potentially negative outcome. It also contains a costbenefit analysis component in which the individual weighs the expected benefits of taking a precautionary action against the costs of taking that action. PMT is unique among similar models-including the well-known Health Belief Model (Janz &Becker, 1984; Rosenstock, 1990)-in that it is organized around "two processes that attempt to match the cognitive processes that people use in evaluating threats (the threat-appraisal process) and in selecting among coping alternatives (the coping-appraisal process)" (Floyd, Prentice-Dunn, &Rogers, 2000, p. 409). PMT appears to be the only such model to incorporate self-efficacy as a separate component, which has been shown to be an important influencing agent in motivational, cognitive, and affective processes (Bandura, 1992; Floyd et al., 2000). Sutton (1982) showed, through a meta-analysis conducted on studies of fear-arousing communications published between 1953 and 1980, that increases in the perceived level of fear consistently resulted in increases in acceptance of the proposed adaptive behavior or intention and that increments in perceived response efficacy increased the intentions to select the adaptive response. In a later meta-analysis, Floyd et al. (2000) demonstrated a moderately strong relationship between increases in threat severity, threat vulnerability, response efficacy, and self-efficacy in facilitating adaptive intentions or behaviors. Conversely, they found adaptive intentions or behaviors to increase with decreases in maladaptive response rewards and adaptive response costs. They concluded that PMT may be useful as a framework for developing individual and community interventions.

In a study of tobacco use in young children, adolescents, and young adults age 10-20 years, Sturges and Rogers (1996) found PMT to be valid in these populations. In general, the children did not show many of the hypothesized informationprocessing deficits related to health threats and how to cope with them, but the theory was found to be effective in explaining children's behavior when they understood the coping strategies and believed they could implement them. The authors suggested that children, and especially younger children, should be taught what actions are best in dealing with health risks and how they can effectively execute those actions.

With respect to our current goal of targeting specific health messages for PLD users, PMT helps to address several basic questions: For those who may be at risk of hearing loss from the use of PLDs, what are the specific health and social consequences of engaging in risky behaviors, what strategies and specific behaviors

are effective in eliminating or reducing those risks, and how might those strategies be implemented in ways that increase the probability of adaptive behaviors and decrease the probability of maladaptive ones?

To develop effective interventions for influencing young people to use PLDs safely, Vogel et al. (2007) hypothesized, based on PMT, that if an individual has the ability and selfconfidence to engage in a specific adaptive response (selfefficacy) or believes that the adaptive response is effective in warding off a threat (response efficacy), there will be a positive motivation to perform that adaptive response. For PMT to hold, the threat must be perceived as severe and as having a high personal relevance to which one is vulnerable. If either self-efficacy or response efficacy is low, there will be a low compliance to recommendations to engage in the adaptive response. The probability of an adaptive response is decreased by the perceived rewards of a maladaptive one. Vogel et al. (2007) cited an example of a person who finds listening to loud music during exercise to be both motivating and enjoyable. Such a person might well be willing to risk hearing loss to conform to stylistic norms and youthful images of attractiveness and healthy bodies. Information campaigns aimed at raising awareness of the seriousness of a threat (i.e., using PLDs at high levels can result in irreversible hearing loss) might effectively change listening habits.

Results of a socially oriented public health media campaign by Beaudoin and Thorson (2007) showed that influencing social indicators among adults can effectively advance youth health outcomes. They found that media campaign exposure was positively associated with beliefs about youth development and behaviors toward youth development. Both outcome measures increased significantly over time with the dissemination of the campaign's television and newspaper advertisements and increased only among respondents who were exposed to the media campaign. Such campaigns can influence the two social indicators, which, in turn, can be expected to have a positive effect on attitudes and behaviors related to youth development.

Conveying Targeted Hearing Health Messages

Among others, Henderson et al. (2011) have indicated that hearing conservation programs aimed at young children and teenagers improve knowledge about the dangers of noise and positively affect their behavior. Clearly, health communication messages should be aimed at preventing or minimizing hearing damage by targeting adolescents (teenagers and middle schoolers) and young adults (including college students), while realizing that these two groups may expose themselves to different degrees of risk, primarily due to differences in awareness of risk and personal vulnerability. In this section, we offer recommendations regarding strategies and specific types of messages that we believe should be conveyed to young adults and adolescents regarding hearing health risks from PLD use. While most of these recommendations follow naturally from our literature review, some are speculative and, therefore, warrant further research to test their effectiveness. (Research needs are addressed in the final section of this article.)

First and foremost, all messages should be conveyed via age-appropriate media. These media should include public service announcements on TV, radio (including satellite radio), and online newspapers and blogs, as well as advertisements or public service announcements in magazines and newsletters, and on Internet sites. Messages should be aimed at educating and informing adolescents and young adults about the potential consequences of PLD use on hearing, and they could consist of written articles and postings and links to websites such as YouTube and YouTube Direct. To maximize impact, the messages should feature spokespersons from the health professions and, at some level of involvement, age-appropriate peer groups. For adolescents, attitude shifts toward hearing-healthy behaviors are likely to require multimodality interventions (Griest, Folmer, &Martin, 2007).

Parents and teachers play important roles in modifying and intervening in children's lives and promoting safe listening practices. It is important, therefore, that accurate and relevant messages be directed to them so they are optimally equipped to inform their children and students about the potential risks of PLDs.

Messages should emphasize the gradual, incipient, invisible, and medically and surgically irreversible (permanent) nature of NIHL; signs of potential damage to hearing, such as the frequent need to ask for

repetition in conversational speech; and the negative consequences of hearing loss on safety and on communication, including the effect of hearing loss on maintaining relationships with friends and family. Adolescents, in particular, should be informed that NIHL is usually slow to develop and shows no symptoms until it becomes substantial and permanent.

A major message to instill in all PLD users is that intensity and listening duration are the two most critical factors leading to NIHL. The danger can be reduced, therefore, either by turning down the volume or by listening for shorter periods of time. A good rule of thumb (Fligor, 2009b) is to limit PLD volume to 80% of the maximum dial setting if the listening time is 90 min or less per day, and to limit volume to no more than 60% of the maximum setting for longer listening times.

Adolescents should be informed that tinnitus, or ringing in the ear, may be a warning sign to turn down the volume or to stop listening for a while. Other warning signs are difficulty understanding conversations or difficulty hearing background noises.

The potential advantages and disadvantages of using insert earphones, as opposed to earbuds or supra-aural earphones, should be stressed, especially to young adults. Insert earphones can protect against background noises, resulting in less need to turn up the volume. Inserts should not be used, however, when hearing conversation or background noise is critical. A recommendation to use insert earphones should be accompanied by a reminder that there are some situations requiring alertness to background noises for reasons of personal safety. Adolescents should be warned that turning up the volume to block out environmental noises can be extremely dangerous, such as when crossing a busy street. Young people of driving age should be warned of the dangers of wearing earphones of any type when operating a motor vehicle.

Members of our profession should advocate that manufacturers include warnings on PLDs or device packaging about listening to loud music, and should advocate to physicians and other medical personnel that they should routinely convey health communication messages regarding PLD use during patient visits. Pediatricians as well as family medicine and primary care physicians are in key positions to provide basic information on the preventability and negative consequences of NIHL, as well as the identification and referral of patients with suspected hearing loss. These medical personnel can be a major influence in preventing NIHL. They need to consider PLD use as a high-priority health issue and discuss the health risks of PLDs in consultations with their younger patients.

Based on a Zogby International (2006a) survey and on the work of Vogel et al. (2007), several subgroups of young people should be specifically targeted. Males may be especially prone to NIHL through loud music from PLDs, and they should be warned about the need to keep volume levels low or moderate. Young people of Hispanic or Latino descent, as well as other minority groups, should especially be warned regarding listening to music that is too loud. Hispanic teens have been shown to use PLDs for longer periods and at higher volume settings than the general population of teenagers, and Hispanic adults appear to be experiencing higher rates of hearing loss than non-Hispanic adults, Hispanic teens, and teens in general (Zogby International, 2006a). Preventive efforts should also target adolescents in prevocational educational programs and those who are not living with both parents (Vogel et al., 2007).

Children, young adults, and parents should be alerted that PLDs are not the only potential source of preventable hearing loss. Adolescents, in particular, should be taught the negative consequences of hearing loss, healthy listening behaviors, and possible preventive measures that will protect their hearing throughout their lives. Messages regarding the need to wear ear protection when working at noisy jobs, performing noisy household activities, or participating in recreational activities-including attendance at rock and other music concerts-are crucial in protecting hearing throughout the lifespan. Where rock concerts are concerned, information should be provided about the commercial availability of musician's earplugs.

Adolescents should be warned that listening to a PLD earphone in only one ear may increase the likelihood of hearing loss in that ear because monaural listening requires a higher intensity than binaural listening to achieve

the same loudness. Because PLDs do not have to be loud enough to be heard by others to damage hearing, adolescents and young adults should be informed that warnings by parents or others to turn down the volume may not be sufficient to prevent hearing loss. Children and their parents can engage in selfcontained programs that are already available, such as Listen To Your Buds (American Speech-Language-Hearing Association, 2010), Dangerous Decibels (www.dangerousdecibels. org; Griest et al., 2007), and Wise Ears! (National Institute on Deafness and Other Communication Disorders, 2010). These programs offer tips and activities designed to conserve hearing and prevent hearing loss. The Dangerous Decibels campaign teaches safe listening practices and has been used successfully in children in Grades 4 through 7 (Griest et al., 2007). Delivering these messages to our youth will allow them to enjoy the benefits of PLD technology while avoiding the potentially deleterious effects of noise-induced hearing impairment.

Future Health Risk Communication Research Needs

Clearly, studies of the effectiveness of various media used in implementing the above messages and strategies, singly or in combination, need to be conducted. Definitive studies of pre- and postintervention knowledge, attitudes, and behaviors regarding PLD use, measured through surveys and experimental measurements of preferred use levels, are greatly needed. Future studies should investigate the role of parent monitoring and habit strength, as well as factors that motivate and serve as barriers to the safe use of PLDs. Relationships between hearing health risk campaigns and the degree to which affected populations comply with recommendations should be determined using a variety of attitudinal and behavioral outcome measures. Future research efforts generally should rely less on convenience sample surveys and more on purposive and stratified random sampling techniques, as well as on experimental designs. Theory-based longitudinal studies of frequent users of PLDs are needed to determine the sociodemographic and psychosocial factors that successfully predict strategies and measures that effectively prevent hearing loss. As appropriate, these investigations should include standard and high-frequency audiometric testing. Another significant need is for large-scale prevalence studies of hearing loss, whether from noise or other causes, to include retests of audiometric thresholds and other audiologic data. Such results would allow a determination of whether NIHLs were temporary or permanent. Finally, given the known association between hearing loss and other conditions and behaviors that are broadly detrimental to health-including smoking, lack of exercise, poor dental health, diabetes, and cardiovascular disease (Shah et al., 2009)-risk-assessment studies of these factors might also incorporate exposure to recreational noise and amplified music.

Acknowledgments

We wish to acknowledge the members of an undergraduate honors seminar at Michigan State University who participated in a series of related research projects that inspired this article, including the following students: Alexandra Artymovich, Hazel Atienza, Sameer Bhagwan, Tori Frost, Minyoung Jeong, Alicia Kramer, Fan Lin, Allan Morris, Daniel Pabst, Neil Patel, and Amy Warren. Two student facilitators, Emilie Sweet and Nathan Williams, also made significant contributions. We gratefully acknowledge the Office of the Provost and the Honors College of Michigan State University for administrative and budgetary support. We also thank Brad Rakerd and Kami Silk for commenting on early drafts of the manuscript.

Footnote

1Levels in the ear canal are known to be at least slightly higher than those existing near the entrance of the ear canal, around 7 dBA higher (Keith et al., 2008). Data that do not incorporate a sound-field equivalent correction factor, therefore, are likely to overestimate damage risk.

Even-maybe especially-when problems have become overwhelming, don't expect agreement on what to do about them. . . .

PROLOGUE

Saturday, February 22, 2020

Earth hovered, almost at full phase, breathtakingly magnificent. Distance concealed the works- and blights - of man, and the globe seemed pristine. Its oceans sparkled. Its cloud tops and icecaps glistened. And it was huge: The natural moon, had it been visible, would have appeared only about one-hundredth as wide.

Earth seemed close enough to touch through the exercise room's tinted dome, but Gabriel Campbell held firmly to the handles of the stationary bicycle. Not that he relied on the strength of his grip: He wore a seatbelt, too, and straps bound his feet to the pedals. This world had too little gravity to notice.

His eyes alternated between the vista overhead and the image of Jillian, his fiancée, which he had taped to the bike's digital readout. Strawberry-blond hair cascaded down her neck and shoulders. Freckles lay scattered across that most adorable, pert little nose. Her clear green eyes - and more so, her smile - all but outshone the Earth.

He was here, on Phoebe, to make a future for both: the Earth and the love of his life. In just one more month, he would go home. Then he and Jillian would marry and they would never be apart again.

Basking in earthlight, his legs pumping furiously on the bike, Gabe was pleasantly tired, professionally fulfilled, emotionally satisfied - unaware that before two hours had passed, he would be dead.

Phoebe completed an orbit around the Earth in just less than six hours, and as Gabe pedaled, darkness crept across the face the world. The changing phase of the Earth told him he had been working out for almost two hours.

Sweat soaked his Minnesota Twins T-shirt, and still ahead of him was a stint on the not quite weight machine: the resistive exercise device. Without exercise, muscles atrophied and bones lost mass in Phoebe's minuscule gravity. Four hours of daily workout were mandated, but he would have worked out anyway. He patted Julian's picture. "I'll be plenty fit for you when I come home." Fit, and horny as the devil.

And with no way up here to spend a dime, he would have banked six months' salary with which to build their future. The pay was damned good, too, much higher than anything he could get on the ground. He tried not to think of the premium as hazardous-duty pay.

The bike whirred. A damper raided in the ventilation system. Voices, indistinct, blended with dueling music players. And then, from the comm unit clipped to his sleeve, soft chimes. Gabe tapped the unit. "Campbell."

"We've got a bot in trouble," Tina Lundgren said, her voice throaty. She was deputy station chief of Phoebe base and in command on the night shift. Not that day or night had any meaning here. The station followed Eastern time for the convenience of folks on the ground. "In sector twelve. "

"And it's my turn to go outside." Hell, Gabe was happy to go out. Only a handful of geologists had ever left Earth, and be was one of them. Had there been any way to get Julian up here, he would want to stay forever.

"What's the problem?"

"Stupid bot tangled itself up in a rock jumble. Otherwise, it's healthy."

Likely a thirty-second task, after an hour or so to suit up and trek halfway across the moonlet. Good deal.

Tina contacting him meant that he was in charge of the excursion. But no one went outside alone- too many things could go wrong, Gabe asked, "Who else is on call tonight?"

"Thaddeus and Bryce. Shall I give one of them a holler for you?"

"I'll take Thad. Newbie could use the practice." Gabe eased off his pedaling. "And no, don't call. I'm in the gym. I need to cool off first." Outside was not the place to get stiff and inflexible.

After winding down for a few minutes, Gabe unstrapped his slippers from the pedals, unbelted, and, carefully dismounting, firmly planted a slipper on one of the deck's Velcro strips. Trailing damp footprints, he crossed the

exercise room, the Velcro pads on the soles of his slippers zip-zipping with each step.
At the hatchway he took hold of the handrail that ran along the corridor ceiling. The Tarzan swing was the quickest way through the station. Many of his crewmates would be asleep, and he kept a Tarzan yell to himself.
Thaddeus Stankiewicz was not in his quarters, the tiny common room, or the even tinier sanitary facilities. When Gabe tried the machine shop, the hatch squeaked on its hinges.
Thad was new to Phoebe and micro-gee; his surprised twitch launched him from his stool and scattered whatever he was working on. Gabe saw cordless soldering pistols, metal tubes, metal rods, wire coils - and, writhing free at the end of its oxygen and acetylene hoses, a cutting torch tipped with blue flame.
Gabe leapt, catching the torch by a hose and with his other hand giving Thad a firm shove clear. The push - equal and opposite reactions - brought Gabe to a near halt at mid room, above the deck. About a foot: Call it thirty seconds hang time. That was plenty long to give Thad a tongue-lashing for his carelessness.
Newbie looked so flustered that Gabe relented. He killed the torch and merely glared as Thad, who by then had grabbed a bench edge, began gathering parts (of what?) and cramming them into his pockets. Stankiewicz was short, broad-shouldered, and intense. His thick black eyebrows and deep-set eyes made him seem perpetually brooding. He wore a standard station jumpsuit, the royal-blue version, with its integral Velcro slippers.
Finally touching down, Gabe slid his foot until it engaged a Velcro strip. "What are you working on?"
Thad shrugged, looking uneasy. Embarrassed? "Personal project."
The station offered precious litde privacy, so Gabe let it go. "A surface rover got stuck. You and I are up to extract it."
"Okay." Thad kept grabbing and stowing the scattered pieces of his project. "Almost done."
"Leave that, Newbie. We have a job to do."
They made their way to the main air lock. The closer they got, the more dark streaks and splotches marked the gray metal panels that lined the corridor. You couldn't help but track Phoebe's dust and grime into the station, and once inside, the stuff found its way everywhere. The crew vacuumed endlessly, but it was a losing battle.
Their spacesuits were filthier than the interior halls and no longer permitted in most of the station. Once you couldn't change in a closet-sized cabin, bracing yourself between opposing walls, the best place to suit up was inside the air lock.
In dthe air lock, back to back and studiously ignoring each other, the two men stripped. Even more studiously they ignored jostling and brushing into each other.
The body suits fit snugly against bare skin. Donning a very elastic body suit in the allbut-nonexistent gravity was like squirming into a sausage casing - underwater. Every nudge and bump sent them careening off bulkheads and decks and each other. Still, these mechanical counterpressure suits beat the hell out of bulky, pressurized spacesuits. Gabe had tried an old-style suit once in training. It was easier to get into, but way more massive. Inertia varied with mass, not weight, and fighting that much inertia was exhausting.
Gabe finally wriggled into his suit and helped Thad finish getting into his own. "Check me out, " Gabe said. He launched himself, with a bit of practiced footwork, into a slow, midair pirouette.
"You look fine," Thad said.
The answer had come too quickly. Anywhere that the suit failed to settle securely into place, fluid would pool beneath. Gaping was the major issue with the skin suits, with the crotch area especially problematical. It wasn't as if Gabe wanted another guy checking out his crotch, but he wanted even less to have blisters down there from an ill-fitting suit. "Check it again," he snapped.
Done properly, spacesuit checkout took time. Eventually, though, their suits were wrinkle-free and without sags or pouching. They mounted and sealed the compression neck rings to which their helmets would attach. They slipped on their backpacks and checked readouts for everything: oxygen, heating, sensors, radio, batteries. Their helmets and air hoses were locked into place.
They stowed their indoor clothes, Thad's pockets clanking, in lockers near the air lock; they buckled on tool

belts and tether reels, stuck emergency maneuvering guns in their holsters, and pulled on gloves and boots. Ready at last, Gabe configured the airlock controls for surface access.
"Oscar, end-to-end system check," Gabe said. Status messages, the text all green, scrolled down the inside of his helmet visor. He had named the voice-activated user interface Oscar as a nod to the suit in Have Spacesuit, Will Travel, a book he had loved as a child- and because, crammed into this suit, he knew how a sardine must feel.
"Comm check, Thad," Gabe radioed on the public channel.
"Back at you," Stankiewicz said.
Gabe called, "Tina? Two robot wranglers set to go outside."
"Happy trails," Tina answered, yawning. "Stay in touch."
"Roger that." Gabe tapped the airlock control panel. Pump noises faded as air was sucked into holding tanks. He felt the first stirrings of warmth from the heating elements in the thermal layer of his suit. Light poured inside as the outer hatch opened. Shrunken to a crescent, the Earth still shone more brightly than a full moon. For now, the moon itself remained hidden behind the Earth.
Newbie gestured at the ladder. "Age before beauty."
"Pearls before swine."
Gabe grabbed the ladder rails and climbed. He paused on the third rung, with only his head and shoulders above the surface. The horizon was freakishly close. Despite earthlight, the landscape was only a dim presence, less reflective than asphalt. Without its coat of rocks, soot, and hydrocarbons, Phoebe's ice - the ice they were here to mine, the ice that could change everything- would have streamed off as a spectacular comet tail.
His grandparents still talked about where they were, what they had been doing, when they first heard that President Kennedy had been shot. For his parents' generation, and even for some of Gabe's own, the event seared into the collective consciousness was 9/11. The World Trade Centers crashing down had marked Gabe too- he had been sixteen that day- but the news that had truly marked him, had changed everything for him, even more than 9/11 or the Crudetastrophe, had come a mere five years ago.
As though it were yesterday, he remembered: a rumor at first, run rampant on the blogosphere, then the hastily called presidential address. A space rock, a big one, was headed Earth's way. It was not dinosaur-killer sized, not quite, and the likelihood it would hit Earth was only one in a thousand - but no sane person would leave home against those odds, let alone bet the future of civilization. The rock had to be deflected, and despite its many woes only the United States had the capability to tackle the job.
But the excitement, the game changer, was this: Rather than deflect the rock away, NASA would undertake to aim it more precisely at Earth. To ensure capture of the object. To exploit its resources and forever change space exploration.
And to hell with whether anyone else thought this was a bad idea. Gabe had never encountered much in the way of presidential leadership. It was exhilarating.
He had long ago lost his youthful interest in the space program. Decade after decade of pointlessly circling the world, scarcely skimming the top of the atmosphere: What was the point? No one cared anymore.
But suddenly there was a reason. Saving the planet. Maybe, in the process, pulling the country out of an economic abyss. And to be honest- adventure. Faster than the president could finish speaking that night, Gabe had vowed he would be an astronaut. Somehow.
That rock - only it had turned out to be far more complex and interesting, a dormant comet - was now Earth's second moon. Was Phoebe. And once again, be was about to explore its ancient surface.
"The view here is less interesting," Thad radioed from the bottom of the air lock.
"Sorry." Gabe unreeled four feet of tether, clipping its carabiner around the staked cable labeled "sector twelve." He clipped a second tether to the guide cable before grabbing handholds outside the hatch and pulling himself

up and out. He waited ten feet along the cable until, gopherlike, Thad's head and shoulders appeared.
"Two tethers," Gabe reminded the newbie.
It was easier by far to fall off this toy world than to cross it. Phoebe was roughly a sphere a mile and a quarter across- where rough better described the body than sphere. It was round in the sense that a popcorn ball was round, with stony lumps taking the place of popped kernels and veins of frothy ice- and in spots, only vacuum - taking the part of molasses. And in the sense that a popcorn ball remained a ball after it had been whacked a bit, dented here, flattened there. Phoebe was less a single object than a rubble pile loosely bonded by its mutual gravity. If its orbit had dipped much lower, the tidal forces from Earth's gravity would have ripped the little moon to shreds.
"Two tethers," Thad repeated. "Done. After you, Pearl."
Gabe pulled himself hand over hand along the cable, coasting above the inky surface. His eyes insisted he was soaring up a cliff face. Gravity's feeble tug told his inner ears he was falling into the cliff face. His gut wished eyes and ears would come to some agreement.
After twenty yanks Gabe stopped pulling. "Coasting," he radioed the newbie.
"Thanks. The view from behind is unattractive enough without climbing up your butt."
Gabe slowed with gentle hand pressure against the cable at the first glint ahead of a piton anchored in the rock. Carefully he undipped one carabiner and snapped it back onto the cable on the opposite side of the ring. He did the same with his second tether. He made sure Newbie followed the same fail-safe procedure before resuming the trip to sector twelve.
The surface lights, antennae, and trash dump of the station dropped behind the too close horizon. But a status icon in his HUD shone a steady, reassuring green, confirming connectivity with Tina and the command center. The metal guide cable did double duty as an antenna.
Every hundred or so feet a piton interrupted their glide, and in such short increments they made their way toward sector twelve. After ten minutes Gabe checked in with Tina. Twice he saw survey robots - their silvery, octopoid shapes unmistakable - creeping along the surface. The second bot's instrument suite must have sensed a buried ice seam, because the machine was staking a radio beacon. Had Gabe cared to tune to the proper frequency, he would have heard soft beeping from the marker.
Ice meant water. Water meant oxygen and hydrogen. And water, oxygen, and hydrogen already in near-Earth orbit- not lofted from Earth's surface or the permanently shadowed polar craters of the distant moon at the cost of thousands of dollars per pound-were dearer than gold or platinum. So, too, whatever mineral wealth could be wrung from the rocks of Phoebe. On scheduled outings, he continued to survey for exploitable resources.
It was said: low Earth orbit is halfway to anywhere in the solar system. That was a metaphorical truth, almost poetic. Half the work of going anywhere in the solar system was expended fighting Earth's gravity. Building power sats with Phoebe's mineral resources, beaming down solar energy to an energy-starved world, would be only the beginning. Phoebe would be the gateway to the planets.
Away from the station the moonscape dissolved into a shadowy sameness. They passed the pilot distillery sited at a safe distance from the habitat. Parallel glints revealed pipes snaking across the dark surface, delivering water, oxygen, and hydrogen to the base.
Gabe played tour guide, pointing out the little world's interesting features. "On our left, the thermal nuclear rockets that nudged Phoebe into orbit." He glanced at his Geiger counter, even though workers had long since recycled the uranium fuel rods in the base power plant. No matter how many powersats got their start here, Phoebe, forever behind its sunshield, would stay nuclear. "And on our right, the Grand Chasm. It's no great shakes by Earth standards, but relative to Phoebe, it's huge."
"Uh-huh," Thad said.
Newbie had been moody since they left the station. As for what preoccupied him; Gabe could only guess. Maybe no more was at work here than that Thad- like most of the crew - was an engineer, without interest in

Phoebe itself. When Thad deigned to interrupt the travelogue, it was always with practical questions. About pressure suits, their related gear, and how soon anyone would come after them if comm should breakdown... Fair enough. Knowing the limitations and vulnerabilities of the equipment could save a person's life. Although Gabe wished he could share the excitement of discovery, the rocks were not going anywhere. Maybe Newbie would lighten up after he got more comfortable with his equipment.

They glided past the infrared telescope. Good, Gabe thought: we're halfway there. About all he understood about IR astronomy was that hot objects emitted infrared, so you wanted your infrared instruments kept cold to minimize their own intrinsic thermal noise. Behind its sunshield, Phoebe was about as cold as anywhere in Earth's neighborhood ever got. The 'scope's cryocooler, powered by the base nuclear reactor, kept the IR sensor colder still.

He slowed or stopped whenever a surface feature caught his eye, but even a cursory look said most of these rocks were yet more carbonaceous chondrites and silicates. Two bits of stone he could not immediately identify went into his sample bag, for tests back at the station.

He was curious about this tiny world, even if there was no point in discussing it.

Isotope dating of previous samples said Phoebe was more than four billion years old. So why did it still exist? Its desiccated, rocky crust was not that impressive as an insulator. Had it always followed the orbit in which it had been discovered, swooping inside Earth's own orbit, Phoebe's ice would have sublimated long ago, its rocky remains dispersed into a short-period meteor shower. Of course if it had always followed that orbit, the Near Earth Object survey would have spotted Phoebe years earlier. Or Phoebe would have smacked Earth before anyone even knew about deatii from the sky.

So Phoebe had had another orbit, an orbit more distant from the sun. Planetary astronomers had yet to work out Phoebe's original path and what planetary close encounter might have sent Phoebe diving at the Earth. Gabe guessed there was a Nobel waiting for whoever figured it out.

As the Earth waned and the landscape faded into darkness, he had Oscar project a topo map on his HUD. The blinking red dot had them most of the way to the green dot representing the stranded bot. Pits and ravines, ridges and rocky jumbles leapt out of the map image. He tugged his tethers once, twice for reassurance.

"Let's stop for a minute," Gabe called. New Earth was imminent, and Newbie was in for a treat. "Watch the limb of the planet."

Earth's crescent became the thinnest of arcs, then disappeared.

A pale, shimmering arch - part rainbow, part oil slick - emerged from the darkness. Phoebe's sunshield. The free-flying Mylar disk that hovered above Phoebe warded off the sunlight that might yet boil away precious ice as boots and robot tentacles and, eventually, mining operations scraped through the insulating surface layers. The shield's sun-facing side reflected most of the light that hit it. What little sunlight penetrated the shield-the bit they could see- was scattered by the backside's granular coating.

For an endless moment the arch, large but faint, was the brightest object in the sky. Then the trailing edge of the shield, too, slid into the Earth's shadow, abandoning the sky to stars like chips of diamond.

Now the sole clue to Earth's presence was a hole in the star field. Even with eyes fully adjusted to the darkness, from this altitude Gabe could not spot any city lights. He could pretend that all was well below, that the world was not divided between energy haves and have-nots.

"Show's over," Gabe said. He switched on his helmet lights. An instant later, Thad activated his own. "Pretty cool, though, don't you think?"

Thad only grunted.

"So, Thad. What were you making in the shop?" Gabe was just making conversation. Skimming the pitch-black rock face in the near-darkness was eerie.

He felt a tap-tap on his calf and twisted around. Thad had only one hand on the guide cable, waggling his other hand. Two fingers were raised.

"Oscar, private channel two," Gabe ordered. "Okay, Thad. What's going on?"
"Private channel two," Thad repeated. Finally, he added, "You'll keep this to yourself, right?"
"If that's what you want."
Hand over hand, they went. A rim of sunshield reappeared just before the Earth returned as a new crescent. Gabe doused his helmet lights. On his HUD the red and green dots were converging. Another few minutes and they would veer from the guide cable.
Eventually Gabe prompted, "Well?"
"Okay. I put my life in your hands." Thad sighed. "I have a thing for Tiny."
Tina Lundgren was big for an astronaut, even a male astronaut. The nickname was inevitable-and you used it within her earshot at your own peril. Gabe had to admit that, in an Amazonian kind of way, she was sexy. And she was one of only two women, and the only unmarried woman, on Phoebe. Gabe understood Thad wanting this conversation on a private channel.
Having bared his soul, Thad went on and on about Tina's womanly charms.
"Uh-huh," Gabe finally interrupted. "And you were cutting pipe as an outlet for your unrequited love?"
"Not exactly. " A rueful laugh. "I'm making a still. Whether or not homebrew appeals to her, I figure it won't go to waste."
"Does she know how you feel?" Gabe asked.
"Not from me! Not yet. Frankly, the woman scares the crap out of me. Maybe that's why I have to have her."
To their left, a ghostly plume: an ice pocket flashing to steam bursting from the ground.
Behind its sunshield Phoebe should be colder than the night side of the moon: For two weeks out of four, every part of the moon but a few deep polar craters felt sunlight. But shield or no, some sunlight did reach Phoebe. No software was perfect, and occasionally the sunshield - tugged by Earth, Moon, and Phoebe, pushed by the solar wind and by sunlight itself, balancing the many conflicting forces with its own feeble thrusters- drifted out of position. Whenever that happened, sunlight beat directly on the surface. Even when the shield balanced perfectly, the traces of sunlight penetrating the shield scattered in unpredictable ways. Earthlight and moonlight were, in the final analysis, echoes of sunlight. And heat leaked from the underground base and its nuclear power plant. All that energy mingled, meandered, and reradiated in unpredictable ways.
And so, seemingly at random, little geysers. The vapor was too diffuse to do any harm. Most times. If you were unlucky, a geyser could sweep you right off Phoebe.
"A still," Gabe repeated, his thoughts divided between the plume, already trailing off, the topo map on his HUD, the landscape sliding by inches beneath his visor, and the conversation. Ethyl alcohol boils at a lower temperature than water, so alcohol fumes waft up a still coil before water vapor. You separated out the early condensate. But up comes of having gravity. "Will a stiil even work in Phoebe's grav-"
Too much happened at once, the sequence unclear:
-A sharp tug on Gabe's backpack.
- Thad saying, "Wrong answer."
-A power alarm.
-A second yank.
-Helmet lights and HUD going dark.
-A hard shove forward.
Gabe twisted around. Earthlight showed Thad a good twenty feet away, receding. Just staring. And bulging from the mesh pouch of Thad's tool belt: two battery packs.
Without power for his suit's heating elements, Gabe would freeze within minutes. Already the cold seeped into him, body and thoughts turning sluggish. He got his feet beneath him, even as he ripped lengths of tether from their reels. He leapt.
His right foot slipped on loose gravel and he sailed far to the side.

The shorter tether pulled him up short. Its yank started him spinning even as the tug started him back toward the surface. Too slowly. He took the maneuvering pistol from its holster- but it slipped from fingers already numb with cold. As he drifted down he managed to grip a rock outcropping.
All the while, maintaining his distance, Thad watched. Stared.
"Why?" Gabe screamed. Not that his radio worked without batteries. Not that his shout could cross the vacuum. "Why are you doing this?"
Maybe his murderer read Gabe's lips. Whatever the reason, Thad shrugged.
Gabe advanced. Thad retreated.
As cold became all, as consciousness faded, the last thing Gabe saw was the waxing crescent Earth.
Earth no longer seemed close enough to touch.
"He just went nuts!" Thad said once more.
With minor variations the words had become his mantra. First with Tiny, when he had called in from across Phoebe about the "accident." Over and over with Bryce Lewis and Alan Childs after they joined Thad on the surface. And now hopefully for the last time, in the station's comm-gear-packed command center, with Lyman Hsu, the dour station chief.
"Details, please." Hsu rubbed his pencil-thin mustache as he spoke.
Thad ignored the request. "You should have let me go with the other guys. You can't imagine what it was like." I damn well hope you can't imagine it. He struggled to understand it.
"You'd been outside long enough for one day. You know the rules."
Because their utility craft were little more than flying broomsticks: compressed-air bottles, saddles, and minimal controls mounted to latticework frames. A counter-pressure suit was your only protection.
"But I don't have to like the rules," Thad said. Which, emphatically, he did not. What if he had overlooked something? Joining the rescue team might have given him a chance to cover his tracks.
"Details," Hsu prompted.
"You heard Gabe switch to private channel two." It had all come down to Gabe taking his cue, because everything on the public channel got recorded. Sooner or later, he would have figured out what Thad was building. Certainly the bullshit about Tiny and making a still for her would not bear scrutiny. That fable was all Thad could come up with on the spot, blather to occupy Gabe's mind until they got farther from the station.
"When I linked in, Gabe was already mid-rant. He missed Julian, unbearably. He knew- but couldn't explain how- that she was cheating on him. He loved her and needed her and couldn't bear for anyone else to be with her. He would show her. And then" - Thad paused dramatically - "he undipped his tethers."
"And you. . . ?"
"What do you think, Lyman? I tried to talk sense into him, damn it."
"And not a word of this reported to base."
"I didn't dare switch channels! There was no telling what Gabe might do if I wasn't on. If I didn't respond when he expected an answer."
"And he jumped anyway."
"As I keep telling you," Thad said.
He had never been much of a basketball player. On a good day, his vertical leap was two feet. On Phoebe, that was more than enough leg strength to vault two men and their gear past escape velocity. He had let go of the body, untethered, before coming to the end of his own fully unrolled tethers. After the ropes pulled him short with a jerk, Thad had watched the corpse recede into the darkness.
Hsu tipped back his head, staring through the command-center dome. "He had second thoughts."
"What do you mean?" Thad asked.
"Every indication is that Gabe froze to death. But when Tina and Lewis found Gabe, the suit heater was on. He must have been in late-stage hypothermia by then, half delirious. It's a marvel his suit still recognized his voice."

Hsu sighed. "By then it was too late."
The heaters kicked back on once Thad replaced the batteries. Not done till Gabe was unequivocally dead.
"It's a shame," Thad said, meaning it. Gabe was not a bad guy, only in the wrong place at the wrong time.
"A damn shame."
Silence stretched awkwardly. After a while Thad said, "It's been a hell of a day. I'd like to . . . hell, I don't know what." Except that he knew damn well. He had to finish what Gabe had interrupted, and get everything stashed away. At least then the man would have died for a reason. "Something other than relive this disaster."
Hsu nodded. "Sounds like a good idea. Get some sleep."
"I will," Thad said. And wondered if he could.
CONVICTION
2023
Monday, April 10
Marcus Judson slipped into the back of the downtown Baltimore hotel ballroom more than an hour late. Though the room was packed, it did not seem like anyone was having a ball. Certainly not his colleagues huddled at the speakers' table at the opposite end of the room.
He surveilled from behind a freestanding sign that read The Power of Powersats: a Town Meeting. From the way Jeff Robbins, one of the EPA representatives on the dais, blotted his face with his handkerchief, the townsfolk bore, however metaphorically, torches and pitchforks.
The PowerHolo orientation spiel (of which Marcus was thoroughly sick, after many such gadierings) ran about thirty minutes. That meant the Q&A session had just begun. It did not bode well to find Jeff already wound so tight. Plenty of head-in-the-sand types in the crowd, then. Damned Luddites.
Marcus hated being such a cynic - but he was more this way every day.
This could have been any public meeting room anywhere. High ceiling. Cheap carpet and cloth-covered walls to muffle the audience noises. Sidewalls comprised of narrow segments that, folded into accordion pleats, would open into other, similar rooms for additional space. Recessed ceiling lights. Amplifier and loudspeakers deployed across the foot of the dais. HoIo projection console.
Men and women filled the rows of chairs, and yet more people had queued up in the aisles for turns at the audience microphones. At the right-hand mike, a tall, balding man, his sleeves rolled up, was gesturing grandly.
Marcus had arrived too late to catch the man's point. If he had a point. They often didn't.
"... would be a better use of public land," the balding man finally concluded.
"Thank you for your comment, " Lisa Jackson began. As she - as all the panelists - had been trained. "We agree that parks are important. That said, so is a sufficiency of electrical power. We at the Department of the Interior must consider both."
The novelty of powers at town meetings was long past; the room's lone tripod-mounted camera might feed only the municipal Internet server. With no media visible the protocol would have been the same, because half the audience sat holding comps or phones or datasheets. Any slip-up would be on YouTube within minutes. So all panelists were trained in changing the subject. Better a non-answer than an impolitic one.
If inconvenient questions were to be evaded, what was the point? Why hold these town meetings at all? Marcus had asked, and his question, evidently, was also impolitic. "It's policy," a long-ago boss had once told Marcus in similar circumstances. "It doesn't have to make sense."
But coaching by a NASA spin doctor was not what had made Marcus a cynic.
He half listened, half pondered how and when to move to the front of the room. On the dais, behind the long, skinny table and its billowing, ruffled skirt, sat eight chairs: two places each for Interior, Energy, the EPA, and NASA. The lone unoccupied seat was Marcus's.
With Lisa expounding from five chairs away from the empty seat, this seemed as good a time as any for Marcus to claim his spot.

He edged through the least crowded aisle, murmuring apologies as he went, answering dirty looks by tapping the NASA ID badge clipped to his suit lapel. I'm with the government. I really am here to help.
Once through the crowd, he slid into the empty chair at the speakers' table.
Ellen Tanaka, NASA program manager for the powersat- and Marcus's boss - looked weary. They all did. Her eyes, too myopic for LASIK, were owl-like behind thick, round lenses. She covered her mike with a hand. "Good of you to join us," she whispered.
That he had texted ahead changed nothing. Everyone had made the drive that morning from somewhere in metro DC. She would not want to hear about the rain, the line at the gas station, or signals flashing red throughout Fairfax County because the traffic management system had crashed or been hacked. He would not have, either.
"Car trouble," he mouthed. "Sorry."
Lisa was still answering the balding man. "We'll be using property already dedicated to power generation, in this case for ground-based solar power. In particular, we'll retrofit selected solar farms with arrays of short antennas suited to receiving power downlinks. Land recycling, if you will - very environmentally correct. The antennas will be vertical, scarcely blocking any sunlight to the solar cells on the ground. So, you see, the powersat demonstration does not preempt any parkland."
"But that land shouldn't be wasted on-" "Thank you for your comment," Ellen interrupted. "I'm afraid that's all the time we have with so many others still waiting." She pointed to the head of another line, where a middle-aged woman, rail thin, her face tanned and leathery, clutched a folded sheet of paper. The woman wore the judgmental expression of a Resetter. "Yes, ma'am?"
Marcus and Ellen took turns moderating these meetings, because NASA's part of the solar-power-satelite project drew the fewest questions. Public comments mostly concerned public safety, energy policy, and land use. Never mind, Marcus thought, that Powersat One, the full-scale demo system nearing completion, would be the largest structure ever built. Or that NASA was constructing PS-I in space, where neither night nor weather could interrupt the sunlight streaming onto its solar cells.
But all that dependable- and desperately needed - solar energy became useful only when it reached the ground. And once brought to Earth, the power had to be distributed far and wide. Terrestrial solar farms already had connections to the national power grid. Siting the downlink antennas amid the ground-based solar farms just made sense.
To Marcus, anyway.
"About that downlink," the thin woman began, frowning. "'Downlink' sounds like an Internet connection, and that's more than a little disingenuous. Your downlink is nothing so benign. You're talking about microwaves. A gigawatt or so of microwaves. If you turn on that satellite, it'll roast anyone unlucky enough to encounter the power beam."
"No, it won't," someone muttered from down the table- and a mike picked it up.
Marcus leaned forward to see who had gone off-script. Apparently Brad Kaminski, from DOE. He was clutching his mike stand, and a bit red in the face.
"Um, thank you for your comment," Brad backtracked. "Yes, downlinks from the power satellite will use microwaves. That's for a good reason: Earth's atmosphere is transparent to microwaves. By beaming microwaves, we can harvest most of the power on the ground.
"But as for safety, ma'am, there is no cause for concern. The beam is strongest at its center. By the edge - "
"How strong?" someone in the crowd hollered.
"About like direct, overhead sunlight," Brad said. "By the edge of the- "
"Like a second sun beating down on you," the woman at the mike said. "That should be healthy."
Brad persisted. "By the edge of the collection area, a zone miles across, the beam has attenuated to well within public safety standards."

The woman laughed humorlessly. "You expect the birds to mind your fences?"
From deep within the crowd, a snort. "Lady, do you have any idea how many birds get chopped up by wind generators?"
"Forget the damned birds!" someone shouted back from across the ballroom. "Just keep the lights on and my car charged."
Taunts and insults erupted, on every side of the issue. Cameras big and small pointed to memorialize the chaos. It took Ellen several minutes to restore order
In order that more decorous criticisms could resume. That powersats were: unsafe, unnecessary, or poor investments. That if only everyone conserved, instead of wasting resources on foolishly audacious projects, it would be better for the United States and the entire Earth, too. That the country could extract additional energy from the tides, or build more wind farms, or re-shingle more roofs with solar cells, or grow more biomass, or ... do anything other than the powersat project.
And from the opposite end of the opinion spectrum: That the wind did not always blow when people need power. That-duh!- the Sun did not shine at night or do much for snow-covered roofs. That sunlight beating down on Arizona did nothing for New England. That people shrieking "energy sprawl" against a few square miles to be used for East Coast microwave downlinks fooled no one by suggesting new high-voltage power lines could be built across the continent from solar farms in the southwestern deserts. That the NIMBYs had even less credibility proposing huge new storage systems to save solar power for exploitation at night. And that if the tree-huggers did not wise up, civilization would grind to a halt. Shivering in the dark.
Since the Crudetastrophe, oil was scarce and painfully expensive. That did not make gasoline any less essential. There simply was not enough electrical power generation to cope with the hurried - and ongoing - switchover to plug-in cars; if there had been, the overburdened power grid could not reliably distribute the added load. Marcus did not bring up any of that. No one on the panel did. They were not permitted to say anything verging on politics, geo- or other.
Do it all, Marcus wanted to shout, but that was yet another truth no one on the panel was permitted to speak. Any other means of power generator, distribution, or conservation was someone else's project.
From time to time it was his turn to field a harangue. He dutifully thanked whomever for their comment and, all too often, parroted some preapproved, eminently inoffensive platitude. And began to wonder if there was any way he could not have become cynical.
If he hadn't been already.
A young woman in a Johns Hopkins sweatshirt reached the front of a comment line. An engineering student, Marcus suspected, because she asked about the radiation environment in space gradually degrading solar cells. When he thanked her for the question, he really meant it. He was an engineer too.
He talked about radiation hardening, onorbit repair methods, and opportunities for in-space remanufacturing. He reviewed the deleterious effects of weather on terrestrial solar cells. This, finally, was a question he could answer without breaking protocol - not to mention an interesting topic - and he pretended not to notice his boss's sidelong glances until she tap-tapped her mike to cut him off. It was almost noon and they were, "regrettably nearly out of time."
Two more danced-around questions and the ordeal was over. Until two days hence, in another city. Marcus forgot which, and it hardly mattered.
This was no way to save a country.
Long after Marcus and his colleagues had collected their things and were ready to hit the road, many of their audience still milled about, arguing in animated clumps. The stragglers showed no sign of clearing the aisles. The wall behind the dais had two camouflaged service doors. Marcus opened one a few inches and peeked out. He found the service hallway empty and, apart from the distant, muffled clatter of pots and pans, quiet. "Shall we?" he suggested to his colleagues.

No one argued.
In the austere corridor, her shoes clicking on the tile floor, Ellen limped along beside Marcus. She had not quite recovered from a skiing accident the previous winter. Ellen was tall to begin with; in heels, she was almost his height. "Not fun, Marcus, but we need public support. It's going to be a big change."
"Understood," he said. And still a waste of their time.
"Not everything can be as fascinating as radiation-hardening techniques for solar cells. " With a laugh, she changed the subject. "What's the car problem?"
"The circuit breaker in my garage tripped overnight." The overtaxed grid, sagging and surging, was beyond anyone's ability to predict-and with every new electric car on the street the load became a little greater, a bit more mobile, and that much less predictable. "The breaker must have popped right after I got home and plugged in the car, because I had about zero charge this morning."
"And you had to buy gas? Ouch. Well, you must have had ration credits left. That's something."
Double doors swung open into the service corridor, the kitchen noises swelling, and waiters rushed toward them bearing lunch trays. Marcus stepped aside.
Twenty bucks and change per gallon. That ridiculous line at the pump. Ration credits he had been saving for a vacation. None of it bore dunking about.
"And Marcus. . ."
The pregnant pause. Her charcoal-gray power suit. Heels. She was way overdressed for the morning's public flogging. "Where are you off to, boss, and what do you need me to cover for you?"
She grinned. "Clearly we've worked together too long. The administrator called last night. He wants a program update today. Hence, you'll be taking my place at this afternoon's interagency coordination session.
I'll mail the minutes from the last session." When the administrator of NASA called, you went. Still . . . "Isn't that task force all career civil servants?"
Which Marcus was not. He was a SETA contractor: systems engineering and technical assistance. Fortunate SETA contractors got involved in everything their government counterparts did. Unfortunate SETA contractors took meeting minutes and fetched coffee. Lucky or not, they spent most of every workday stymied and snubbed by the contractors from the big aerospace corporations who did most of the actual R&D.
If you had to have a supervisor, Ellen was as good as ttiey came. Kendricks Aerospace, prime contractor for the demonstration powersat, balanced the scales. Most Kendricks engineers on the project detested Marcus. Not personally, or even professionally - they would have hated anyone looking over their shoulders. Asking questions. Making suggestions. Auditing their work. Highlighting risks. He got the disdain they would not dare exhibit toward Ellen.
When had he last been able to do, not merely review?
"Trust me," Ellen said. "You won't be the support contractor to sit in."
"What's my goal?"
"Answer questions and take notes. Beyond information exchange, these meetings don't specific goals." She paused. "If anyone tries to pin you down to something uncomfortable, you can plead lack of authority."
Because he had no authority. God, he loathed meetings.
They exited the service area into a carpeted corridor. A wall sign pointed the way to the main lobby. They continued walking. "Okay," Marcus said, "where is this meeting?"
"DOE in Germantown. Nancy Ramirez's office."
Reflexively, Marcus began guesstimating the miles added to today's commute. He must have winced.
"I'd reimburse you for the gas if I could," Ellen said.
But more than that, she had the look that said I wish there were something I could do for you. At least she had stopped asking if he "wanted to talk about it." Because he really, really did not.
As for NASA reimbursing him for the gas, he understood: Her hands were tied. Space Systems Science,

Marcus's direct employer, had bid for the SETA contract at Goddard Space FUght Center without reimbursement for local travel. Shifting local travel costs onto the staff kept the hourly rates a few cents lower. It hadn't much mattered, when Marcus took this job. He had lived only a couple of miles from GSFC then. He told himself he might not have a job if SSS had pursued the work less aggressively.

He told himself lots of things. Other things he just refused to think about.

"But maybe," Ellen added hopefully, "your car charged up during the meeting."

"I wouldn't complain." Even at the hotel's exorbitant parking-plus hourly rates.

But in the two hours he had spent at the town meeting, his car would not have taken much of a charge. The Jincheng was overdue for a battery-pack replacement - which would run him about half of what a new car would cost. New car or new battery? He would put off buying either for as long as he could, rather than support the lithium cartel. Bolivia and Chie, curse them, controlled half the world's lithium supply. Every lithium-ion battery bought anywhere propped up prices for the cartel.

Supporting the Russian oil cartel this morning felt just as crappy.

In the hotel garage, the eight panelists fanned out toward their various vehicles. Coming straight from home, only three had managed to carpool. "Have a good meeting," Marcus said as he and Ellen paused by his car.

"You too," she said. "And don't do anything I wouldn't."

"You should have thought of that earlier. " Smiling, she kept walking.

Marcus's car had accepted scarcely a tenth of a recharge, about what he expected. The car would switch to its little gas engine well before he reached his meeting.

"Destination: Department of Energy, Germantown complex," he announced, backing out of his parking spot.

The console beeped and a reasonable-looking map appeared in the main dashboard display. He tapped the ACCEPT key.

Once he merged into the clotted traffic of 1-695 he activated autodrive, and the car guided itself to the rear of an auto platoon. He found himself nose-to-tail with a late-model blue Toyota. Seconds later, a white cargo van filled his rearview mirror. The van was too close to make out the company logo on its hood.

He had more pressing things to read than logos. Marcus dismissed the map to check and Ellen had already forwarded the he needed. But he had driven too many years before autodrive to conwhile cars not two feet apart joined departed the platoon, and when to both sides, bumper to bumper, eighteen-wheelers blotted out the sky.

With only the ride to prepare, he opaqued windows and began skimming.

He had also been around long enough to expect recession to reduce traffic. Not since Crudetastrophe. Without funding for highways crumbled faster than diminished.

Marcus began reading Ellen's annotated minutes. He stopped noticing (Around accidents? Potholes? The crossing the road? Through the windows, he could not tell.) and from one freeway to the next. The noises faded....

A pop-up usurped the dashboard screen. red letters announced: Power alert. text, scrolling, gave the particulars: a line severed from the NantuckSound wind farm. Terrorism neither indinor ruled out.

Marcus rapped the screen to acknowledge again to retrieve a list of related headlines. The list expanded faster than he could tap through to even a smattering of the articles. Scattered secondary outages across Massachusetts as generators, distribution stations, and power lines overloaded and shut down. Sporadic blackouts predicted throughout New England, possibly rippling down the East Coast, while the grid rebalanced, or until the wind farm's underwater high-voltage line could be repaired. The schedule of preemptive brownouts. Talking heads blathering about unsafe, indefensible infrastructure. Resetter groups saying the same, more nastily. Predictions, into the tens of thousands, how many cars would fail to recharge overnight. The certain spike tomorrow in East Coast gas prices, a buck or more per gallon, when all those cars headed for the pumps. The stock market tanking.

Multiple groups and causes claimed responsibility.
Cursing them all, he went back to Ellen's notes. Too soon, the dashboard trilled: time to disengage autodrive. He took back control and made his way to the DOE parking lot. The charger-equipped slots were all occupied. Sighing, Marcus got out of his car. Another damned meeting. He wondered if ever again he would get to do something.
Wednesday, April 12
"Good afternoon," Dillon Russo told the latest earnest entrepreneur to pass through his office that day.
They were all earnest. It took more than earnest to set yourself apart. He had been merely earnest once. Then he had gotten savvy. And shorted a portfolio of mortgage-backed securities before the markets realized that sub-primes were toxic. And so, became very rich.
And so, here he was....
Who is this woman? Courtney something. One more engineer and MBA, yadda yadda yadda. Dillon had already forgotten her last name. If it mattered, he could find the name in her leave-behind or on his calendar. He did not foresee it mattering.
Speed dating, venture-capital style was a lot like speed dating of the social kind, only even more demeaning. Dillon allotted each petitioner a half hour: fifteen minutes for the pitch, ten for Q&A, and five alone, afterward, to organize any notes he had taken. The lone note for Courtney read not on your life, jotted down before, earnestly asserting her appreciation for his time, she all but backed out of his office.
He dropped her leave-behind into a drawer. She had brought the day's fifth pitch for enhanced cellulosic biofuel production. Her process involved platinum nanoparticles, lots and lots of them, employed as catalysts. As though, even in a world starved for energy, that could make any kind of economic sense.
It hardly mattered. Fail or succeed, anything anyone could hope to accomplish with biofuel synthesis was mere tinkering at the margins. He only cared about opportunities that could make a real difference.
Another make-us-both-a-pile-of-money pitch would come through his door in about four minutes. He used a half minute to get out from behind his desk and stretch. The rest he would spend admiring Central Park, thirty-eight stories below.
At least the biofuel types had done enough homework to know that his interests lay in eco-friendly opportunities. Ditto Noah, the gangly, pinch-faced man pitching virtual-reality tools for high-end telecommuting and Suresh, with a new wrinkle in fuel cells. Those who had not done their homework, who wasted his time with trivial visions for the next big social network or junk food, got the hook. Fast.
Dillon watched a line of mounted police watch a mass gathering down in the park. In theory demonstrations were legal in Central Park, but permits remained hard to come by and the crowd swirled and surged in a pretense of spontaneity. He never could judge crowd sizes, not even from his bird's-eye view. A thousand? Two? It did not help his estimating that the crowd shifted restlessly. When, all but inevitably, the cops dispersed the demonstrators, a new flash mob would simply converge elsewhere in the park.
Permit or no, frequent arrests notwithstanding, the Resetters demonstrated daily in the park. Applauding, if not the Crudetastrophe itself, the resulting economic slowdown - and, with it, the reduced use of fossil fuels - as benefits to the environment and the planet. Opposing new energy infrastructure as only repeating past environmental insults.
Dillon could sympathize with their opinions. But to expect civil disobedience and petty vandalism to change anything? Such naïveté sadly amused him.
Someone rapped firmly on his door.
"Come in," he called.
A blond woman strode in, wearing a severely tailored dark-blue suit. She was short, compact, and very serious.
"Mr. Russo," she began, speaking quickly, not yet halfway to his desk. Very focused. Focused beat the hell out of earnest. "I'm Kayla Jorgenson, of Jorgenson Power Systems. Thanks for seeing me. You won't be sorry."

I'll be the judge of that. "Have a seat, Kayla."
Handing him a brochure, she launched into her pitch. "What the world needs, more than anything, is clean, affordable electrical power generation. We had sporadic petroleum shortages before the Crudetastrophe. Electric cars - not that anyone can produce them fast enough - help only to the degree there is electricity to recharge their batteries. Too often, there isn't."
Focused and aware. Dillon began leafing through her brochure.
She did not let his page flipping distract her. "Why I'm here, in a phrase: ocean thermal energy conversion. OTEC is conceptually very simple - and a vast untapped resource. Any heat engine turns heat energy into mechanical work by exploiting a temperature differential. Steam engines are heat engines, the high temperature that drives them coming from fire heating a boiler.
"Now consider the ocean. The tropical ocean's surface can approach human body temperature, and yet around a half mile below, where sunlight never penetrates, the temperature is scarcely above freezing! Tremendous power-generating potential exists in the differential between the hot and cold layers of the ocean - and with no energy source involved but sunlight.
"I would guess you've been pitched concepts for harvesting wave power. The energy OTEC can theoretically harvest is greater by an order of magnitude. The challenge is in efficiently and affordably ..."
Did Kayla ever stop for air? His wife, while playing her French horn, did somettiing she called circular breathing. What, exactly, Crystal did eluded him- surely the windpipe worked in only one direction at a time- but somehow she could sustain a note indefinitely.
Just as, somehow, Kayla kept up her patter. "... and while the theoretical efficiency of a heat engine operating with such a small temperature difference is about seven percent, past OTEC trials have achieved only one or two percent. With our proprietary technology, we can ..."
Dillon took down his first note. This could be real. He did not begrudge Kayla her full fifteen minutes. "So you're going to save the world," he probed.
"Hardly. We need many ways to generate power, Resetter fanatics notwithstanding. OTEC can be one method. It should be one, in the tropics, anyway. " She rattled off more of OTECs virtues. Finally, she took a breath. "Will Russo Venture Capital Partners back us?"
"I'll have to touch base in-house." That was a stall, because as principal partner Dillon's was the only opinion that mattered. He only took aboard investors cowed by his reputation, being especially partial to the pension funds of small towns in flyover states. Well, there was one exception, but Yakov's interests were . . . different.
Yakov was different: fascinating and worldly-wise. If Yakov sometimes demanded more involvement than Dillon's usual partners, he also brought resources none of Dillon's other partners could offer.
Kayla persisted. "If you have further questions ... ?"
"But I will admit to being intrigued." Dillon spared her the briefest of smiles. "Perhaps sometime I could tour your prototype. " "Absolutely! Her discipline finally slipped. With a grin, she whipped a folded datasheet from her jacket pocket. "Let's set that up now."
"We're about out of time," he countered. "I'll be in touch."
She all but floated from his office- at die last, as naïve as any of the day's supplicants. As naïve, in her own way, as the Resetter activists whom she disdained.
Nodding welcome to yet another earnest entrepreneur, Dillon thought: That's how I can do what I do.
Thursday, April 13
Valerie Clayburn glowered at her datasheet. Neither it nor the wildly colored globe it projected deserved her wrath- but they were here. Telecommuting was fine in its place, but much of her job demanded the personal touch.
And with that moment of resentment, she felt rotten, as though she were shortchanging the sick little boy in the next room.

Not that Simon sounded sick. He was making the deep-in-his-throat revving and growling noise that all little boys make- to the amusement and consternation of their mothers- whether playing with cars, G. I. Joes, or toy dinosaurs.

She had three sisters. None of them ever made sounds like her son and his friends did.

She had once found Simon galloping in circles "flying" a toy stuffed rabbit, its floppy ears bent sideways like wings, making those same annoying/adorable noises. Something she and her sisters would never have thought to try. He had been about three. Smiling at the memory, she went to check on him.

She found him deep in his toy box, playthings strewn about his bare feet. From the doorway to his bedroom, the little-boy noises sounded a bit different than usual. Deeper. Phlegmy. "Back in bed, kiddo," she commanded.

"But Mom. I was only-"

"Doesn't matter," she said. "Pick a toy and get back under the covers."

He emerged from the toy box, one hand clutching little cars and the other action figures. Testing the limits. She let it pass. "Bed. Now. Move."

He dumped his double handful of toys on his blanket. "I have to go to the bathroom."

Predictable. As he passed her in the doorway she felt Simon's forehead: still warm. His blond hair was dark with sweat. The jungle-camouflage pajamas (little boys!) he wore were snug and inches too short, but he would not give them up until she replaced them. If he would only stay in bed, the bare ankles and wrists would hardly matter.

Heading off an "I'm thirsty" stall, she topped off the orange juice in the glass on his nightstand while he dawdled in the bathroom.

With a struggle, she got him into bed. "Tuck me in?" he asked.

"Sure, pumpkin."

Simon made a face. He was nine, too old and rough-and-tough to be anyone's pumpkin.

Not so. She half tucked, half tickled until he giggled. "Now stay in bed," she ordered.

She returned to the kitchen. Elbows on the table, chin in her hands, glower reemerging, she resumed her staring contest with the slowly turning globe.

Saturn's largest moon: Titan.

This was not how any human would - or could - behold Titan, its dense atmosphere all but opaque to visible light. Only radio-frequency waves pierced the perpetual shroud to reveal the tumultuous surface of one of the most interesting - and, in some ways, most Earthlike- bodies in the solar system.

The holo orb was all swathes, indeed layers of swathes, like a world made of papiermâché. Each strip was a separate radar study, some undertaken from Earth, others from fly-bys years earlier by the late, lamented Cassini probe. Swathes varied in color, a distinct hue assigned to represent each radar wavelength. Dark and light shades showed what polarization had been used, the choice optimized for sensing smooth or rough features.

Despite appearances, the mosaic was not constructed from photographs, because radar did not "see" as a camera would. Behind the imagery lay complicated mathematics, embodied in even messier software, that reconstructed topographic features from Doppler shifts, the slightest differences in round-trip signal delays, and echo strengths. (Not that the echoes were strong: At their closest, Earth and Saturn were about eight hundred million miles apart.) Fortunately she had reached the stage in her career when grad students handled the programming scut work.

All those swathes and the riot of colors would have suggested to most people that Titan had been well mapped. Not so. Valerie was no casual observer, and her eyes went straight to the problem areas, mostly adjacent swadies that failed to align. Oh, nearby swadies might appear to match, were meant to overlap, but that could not just be assumed. Scanning a particular bit of Titan from across the solar system was tricky.

Stuck home for the day, if not the rest of the week, eyeballing strips for common features was something she

could do. And deucedly difficult.
Titan was a dynamic place, its surface sculpted by erosion and weather, its methane lakes ever shrinking and expanding, its orbit tweaked and tugged in a complex dance by sixty-plus lesser moons, the entire world tidally flexed by Saturn's immense gravity. Software tried, with mixed success, to align radar images. Human eyes were still the best at matching multiple views of a canyon or lakeshore or hill captured at different resolutions, at different times, from different angles. Nor did the hills always stay put between radar studies. Dunes hundreds of feet tall and hundreds of miles long- dunes not of sand, but of exotic hydrocarbons (looking, the one time a probe had landed to look, like wet coffee grounds - drifted with the seasons. The marvel was that Valerie and her grad students had stitched together even this poor semblance of a topo map.
Here and there, maddeningly, areas remained pitch black. Not yet scanned. Titan Incognita.
Water bottle in hand, she stared at the tan layer- what there was of it. The latest survey had produced hardly any data. No data she might have chalked up to bad aim, but the bit that had come in confirmed proper aiming, and diagnostics confirmed correct operation of the receiver.
So what had happened? A software glitch that somehow discarded the radar echoes? Always possible, but she had seen nothing indicative of mishandled data. Radio interference that perfectly canceled the signal but did not reveal itself? Very implausible.
It took a while for the penny to drop. It took an hour of calculations, punctuated by two quick peeks in on Simon, asleep amid a jumble of toys, to work out the geometry and confirm her suspicions.
There had been interference, all right: The signal bleeping blocked, after a round trip of almost two billion miles. By Phoebe's sunshield.
Of course the Moon, the first-and-real Moon, sometimes got in the radar telescope's way - but on its stately orbit Luna crossed the plane of the ecliptic, potentially blocking the line of sight to other targets in the solar system, only once every couple weeks. Phoebe and its sunshield whizzed around the Earth in less than six hours!
Damnation, she knew that. Phoebe and its shield were small, but her luck was bound to run out.
As it had.
Valerie sighed. She could plan future observations around them, but what a nuisance. Long-term, the observatory needed to reprogram ASTRID- astronomer's integrated desktop- to keep Phoebe-compromised observations from ever getting scheduled. And
And it had not been a penny that had dropped before. Wrong metaphor. A shoe had dropped. No, a big honking boot. And now, so did the other one.
Phoebe was not the big problem. The big problem was everything that Phoebe portended ....
Marcus loitered in a vending room, sipping a cup of lousy coffee, savoring the break from an interminable meeting. Sunlight streamed through the room's window wall, which offered an otherwise uninspiring view of an interior courtyard.
A predisposition to fog from off the Potomac had given this neighborhood its name, but diplomatic obfuscation was what preserved the label. To most of the world, Foggy Bottom meant the State Department, in whose blocky headquarters Marcus had unhappily spent his afternoon. Ellen had gotten a call just as the meeting started. She left, giving him only a you-know-how-it-is shrug for explanation.
Today was nonetheless a change of pace, because this meeting involved international whining. As the demo powersat approached completion, more and more countries were objecting to powersats as weapons of mass destruction.
And so Marcus had gotten to explain microwave downlinks to a roomful of Foreign Service Officers. Yes, the beam carried a lot of power. That was the project's purpose: bringing power to the ground. And of course the beam was concentrated, to minimize the dedicated collection area on the ground.
Then it had been on to safety interlocks. Every collection station had a guide beacon that the power satellite used as its target. If a collection station detected the power beam slipping off-center, off went the beacon and

the satellite ceased transmission.
"Target?" an FSO had repeated.
"A poor choice of words, " Marcus had answered. He wasn't a diplomat. Aimed would be no better. "Directed. The satellite directs the beam at the collection station."
"And beams only at collection stations?" another FSO had asked. "My online identity has been hijacked twice, and you wouldn't believe what a pain in the posterior that was. So you'll understand ttiat I'm just a tad skeptical about how secure any system is."
"Yes, only at collection stations. " In his mind, Marcus had added an exclamation point. And speculated about birthdays and children's names used as passwords. "Downlink coordinates are hard-coded into the powersat. By design, we can only update coordinates physically, on PS-I itself. To update the list of authorized collection stations, we'll dispatch a robot probe."
"Switchable on and off. The downlink point commanded from the ground."
Who wants a system that can't be turned off? "The idea," Marcus had explained, "is to deliver power where it is most valuable, and that varies. It could be the DC area in summer, and maybe only in the hottest part of the day when the use of air conditioning peaks. It could be Fargo in winter, during a cold snap, when the demand surges for heat. Or filling in when some wind farm lacks wind. Or anywhere an equipment failure creates a power shortfall. And by beaming to the downlink station nearest the point of need, we reduce stress on the national grid."
"If I may summarize," the first FSO had jumped back in. What the hell? Were they tag-teaming him? "A gigawatt of focused energy 'directed' at the ground. Steerable beams. It could be a weapon."
"And any satellite launch could become a ballistic missile aimed at the ground," Marcus had snapped in frustration, only to be told he was not being helpful.
To the degree Marcus had ever had control of the session, that was when he lost it. From then until the break, the FSOs had revisited, with painful circumlocution, perhaps every criticism anyone ever made about the U.S., back to those (idiots, in Marcus's opinion) who had objected to American unilateralism in the capture of Phoebe. Diverting a space object, let alone using a nuclear-powered thruster for the dormant comet's final orbital insertion, could be construed as a violation, at least in spirit, of the Outer Space Treaty. (Excuse me: the Treaty on Principles Governing the Activities of States in the Exploration and Use of Outer Space, including the Moon and Other Celestial Bodies.)
In what universe was doing nothing, and maybe having Phoebe hit Earth, the preferred course? The same universe, evidently, where one listened to members of the energy cartels, and the cartels' most dependent and coercible customers, and Third World ankle biters who did not care how bad things got for them as long as they could get in a dig at the United States, and
Marcus stopped himself mid-mental rant. Reliving the experience accomplished nothing. Besides, his geopolitical opinions were doubtiess as well-founded as the engineering opinions of a roomful of diplomats.
"Hey.Judson."
Marcus turned around. One of the FSOs stood in the break-room entrance. Somebody Ryerson. No, Ryerson Smith. "Yes?"
"We're ready to resume," Smith said.
Yay! "Okay. I'll be right-"
When Marcus's cell rang, the caller was not in his directory. He did not recognize the number that came up instead of a name. Not even the area code. "I should get this," he said.
"You know where to find us." Smith headed down the corridor.
Taking the call, Marcus did not recognize the face projected from the cell display. She wasn't someone he would forget, not with those high cheekbones, chiseled features, hazel eyes, and full lips. Her hair, a rich brown, worn shoulder length, nicely framed her face. Forty-ish: about his age. And she looked mad.

Mad about what? he wondered. He said, cautiously, "Hello."
"Marcus Judson?"
He nodded.
"Valerie Clayburn. I'm calling about the powersat."
While she spoke he had queried her area code. West Virginia? "Did you see me on the 3-V news?" he guessed. Damn town meetings.
"Hardly," she snipped. A bit of glower added, aren't we full of ourselves. "I Googled 'powersat NASA program manager' and got your boss. She gave me this number. "
"I'm due back in a meeting, Ms. Clayburn. May I ask what this is about?"
"It's Dr. Clayburn, and I'm calling to schedule a meeting."
Doctor of what? But Ellen had vetted the woman, supposedly, and he had a flexible day coming up. "I have some time open next Monday morning. Will fifteen minutes suffice? Telecon, or will you be coming to my office in Maryland?"
"Fifteen minutes?" She laughed. "Not even close, and anyway, you need to come out here. But Monday works. "
"Why there- and where is that, by the way?"
"Here is the Green Bank Observatory. And why here? Trust me, it'll make sense when you see the place."
Could she be any stingier with information? He had neither the time nor the inclination to play twenty questions.
"I've got to go," he told her. I'll get back to you."
"I'll be here," she said, and broke the connection.
His datasheet folded in quarters because that took less effort than clearing the table, eating (and trying not to taste) a nuked frozen dinner, Marcus sampled the news. In one window headlines scrolled, an all-too-familiar litany of scattered blackouts, spot gasoline shortages, and layoffs. The Russian-led cartel had announced a production cut, sending of futures up ten dollars a barrel. A credit-rating service and a large hospital chain were the latest to disclose that hackers had compromised their customer files. Across the Middle East and Central Asia, more terrorist bombings and sectarian slaughter. In a streaming-video window - for the third day, but still telegenic- squadrons of Resetter activists disrupted construction of a new offshore liquefied-natural-gas terminal near Newark.
Enough, he decided. A few sharp taps on the periphery of the datasheet banished the depressing news and put a virtual keyboard in their place. He started to surf.
The Green Bank Observatory was in Green Bank, West Virginia, which was in the middle of nowhere. Deeper into the middle of nowhere, nonsensical as that was, than he had guessed. Run by the National Science Foundation.
And Valerie Clayburn, Ph.D.? He found her, too. More than enough to beg the question what an up-and-coming astronomer wanted with him. Presumably not for any insight he might offer into distant galaxies or dark energy, or whatever was the hot topic in radio astronomy these days.
Marcus went for a walk to clear his head. The evening breeze was pleasantly cool. Lawn sprinklers muffled the drone of traffic. In most front yards, the cherry trees were in bloom, just past their peak. Even in the many yards with for sale and foreclosure signs. And overhead ...
Urban glow and the crescent moon had all but washed the stars from the sky. Phoebe was too dark to see even during the rolling blackouts. Phoebe's sunshield was for the moment essentially edge-on to him, and so also invisible. But The Space Place sparkled, the brightest "star" in the sky; it put even Venus to shame. The orbiting hotel complex, its surface silvered for cooling, was its own best advertisement.
When he won, say, two lotteries, or struck oil in his backyard, he would be sure to book a stay.
As for the nearly completed powersat, Marcus searched in vain. Alas. He would have welcomed some evidence that his life entailed more than meetings and talk.

When he had called Ellen from his car to ask about her curious referral- and to vent about that afternoon's waste of time at State- his boss, in very few words, speaking more in sorrow than in anger, had shocked Marcus into silence. Hours later, her rebuke still stung: "Have you considered the possibility that someone else might know something?"

Yeah, he had. Only cynic that he had become, it had been a while. Since Lindsey.

By the dim glow of a neighbor's post lamp he texted the enigmatic Dr. Clayburn. CU Monday a.m. around 11.

Monday, April 17

The road trip to Green Bank began painlessly enough, the morning warm and sunny. The observatory banned electric vehicles because they might cause interference, so Marcus had a government motor-pool car and full tank of gas. The car's data link kept dropping out. After twenty miles he gave up on his e-mail.

The first half of his drive, more than a hundred miles, was Interstate, and autodrive did all the work. Leaving behind the DC-area sprawl the scenery was gorgeous, especially as he crested the Blue Ridge, the Shenandoah Valley, lush and green, stretching before him. The sky was a beautiful clear blue. Radio blasting, he drummed on the dashboard to the beat of the music, trying to ignore the many tasks he could, and perhaps should, be attending to at the office. He wondered what he would do when he arrived early.

He got off the Interstate near Harrisonburg. Almost at once he encountered the billboard: not digital, but an old-style, inkand-paper signboard, sun-faded.

The sky, the Tower,
We lust for power.
The Flood, the Burn,
We never learn.
Reset.
Repent.

"The Burn" was not bad- poetically speaking - for the Crudetastrophe. Marcus could not come up with a biblical-sounding term for powersat, either. "We never learn" rang all too true, although his take on the lessons to be learned and the poet's clearly differed.

US 33-W narrowed to two lanes, soon ran out of embedded sensors for autodrive, and lost its shoulders to narrow some more. Sturdy trees crowded right up to the pavement. He slowed way down, and his fretting changed to showing up late. The "towns" along the "highway" became smaller and smaller, and the houses scattered between towns ever shabbier.

Until there were no towns. He guessed he had missed the West Virginia border. By then he was well into the Appalachians, deep within the George Washington National Forest. Negotiating switchbacks. Up and down steep grades, many of them miles long. As were - whenever gaps opened among the trees- the luxuriant wooded vistas. Stunning. Fantastic.

The Blue Ridge? By comparison (at least where he had crested it), that was a speed bump.

And despite Marcus's best intentions, he thought, Lindsey would have loved this drive.

For a long time, he and Lindsey had been great together.

Almost always they had fun. Even when they didn't, when the world made one of them sputter, the other would find the silver lining, or the amusing absurdity of it all, or a way to put matters into perspective. They both liked scenic drives and country inns. They liked hiking and canoeing, classical music and experimenting with exotic cuisines. They learned together to scuba. They mocked the same bad movies.

More than anything, she always knew the right thing to say.

"I know your brother is a slacker, " she had once said, driving home from a miserable dinner out with his parents.

Had Marcus not already loved Lindsey, those few words would have done the trick.

It was nothing against Sean. His older brother was who he was. Sliding through life on charm and modest

ambitions somehow worked for him.
But growing up, "It's not what you know, it's who you know," had suited Marcus about as well as, "Why can't you be more like your brother?"
As a kid, Marcus could never understand why their parents tolerated Sean's mediocre grades and goofing off. The folks did not much like their jobs, but they were far from lazy. Dad was a lawyer and the Washington lobbyist for a national association of rural electrical utilities. Mom was a realtor and had an MBA. Not until well into high school had Marcus seen the bigger picture. Wheedling legislative favors, unloading money pits onto unsuspecting buyers, and coasting through school had something in common. All were ways to game the system. And that apparently was what impressed his parents.
Marcus could never bring himself to see things their way. He wanted to learn, not just make good grades. To make a difference, not a living. To change the world, not game it.
Sean put in four years in general studies at a party college. He went on to become the one-man HR Department at a small company - gloating, to parental approval, that the position lacked quantifiable responsibilities.
Marcus earned a math degree at the University of Virginia and a Master's degree in systems engineering from MIT. He went on to do contract work at NASA where, with luck and if he did things right, maybe he could change more than one world.
What he could not change was his parents' attitude. Their only feedback on Marcus's choices was that he worked too hard, that he let Space Systems Science and NASA take advantage of him. Sean said the same, only more bluntly: "You're a sucker, bro."
But Lindsey got him. He thought he got her.
Ready to move in together, the big question had been: where? His apartment was in Greenbelt, Maryland, near Goddard. Hers was in the City of Fairfax, Virginia, near the insurance company where she worked (and not far, as it happened, from the house where he had grown up). Neittier apartment was big enough for two, not unless at least one of them shed a lot of possessions. Nowhere in the middle appealed to either of them.
He suggested they find a place near her work, and she countered with moving near his. She was so solicitous about what his commute might become, so sympathetic, that it drove him to insist on northern Virginia. Together they found the townhouse in Reston, a beautiful place with a private dock on Lake Anne. He bought a canoe. It was going to be her moving-in present.
Reston would mean an easy twenty-minute commute for Lindsey, and he was thrilled for her. "To return the favor" she insisted that he buy the townhouse solo. The equity growth would all be his - the slow, grinding decline in house prices had to end someday - and she would spare him the complications of entwining their finances. Though he did not follow her logic- there was no hurry, but marriage was the obvious next step - he went along. That Marcus own the place was obviously important to her.
Because for Lindsey, moving in together had become Plan B. Because she was in the running to open and manage a new regional office, in Seattle. She kept that possibility to herself until, two days after closing on the townhouse, her promotion came through. By the end of that week she was off to the Left Coast, for the opportunity she "couldn't not take."
You understand, Marcus. Right? And you own a house now, so be glad.
It hadn't helped Marcus's newfound cynicism that Lindsey's manipulations impressed Sean. As in, "You're a sucker, bro."
West Virginia Route 28, when Marcus finally came to it, was as isolated and unused as the crumbling road that had preceded it. For no discernable reason the national forest he had yet to leave had changed names from George Washington to Monongahela.
He knew he was close when radio reception went to hell. Guessing what he would find, he checked his cell: no service. So he must have zipped past a second road sign unawares: announcement of the National Radio Quiet Zone.

GPS satellites paid no heed to a terrestrial ban on transmission, though, and his nav system worked fine. He spotted the modest sign for the National Radio Astronomy Observatory where he expected, just before the unincorporated town of Green Bank.

A few low buildings clustered near the observatory entrance. As he passed the Science Center, the two cars and one yellow school bus in its parking lot seemed forlorn. He parked outside the L-shaped building Valerie Clayburn's acknowledging text message had indicated.

He was a half hour early.

Bright white dish antennas, one after another, receded into the distance. None stood close enough to offer any sense of scale. So how big were they? Rather than kill time at the Science Center among grade-schoolers, why not find out? He could not have asked for a nicer day for a stroll.

His first stop: the trio of signposts abutting the parking lot. Ambling over, curious, Marcus found placards for the sun, Mercury, and Venus. Earth had a sign not far away. Touring the scale model of the solar system would take him out to the big antennas. He walked to "Mars," only a few steps from "Earth."

Past "Mars" he came to a tollgate-like barrier across the road. Boldly lettered signs announced Diesels only beyond this point and Turn off your digital cameras. A well-trodden footpath circumvented the gate and he kept going. By the time he spotted the Jupiter sign, the first big antenna had caught his interest. It had a descriptive sign too. The dish was forty-five feet across! How big were the antennas in the distance?

Marcus understood the scale of the solar system - intellectually. Hiking it, even at a 1:3,000,000,000 scale, was something else again. "Pluto" and the last of the big dishes were still more than a mile away. He turned around without ever seeing the sign for Uranus.

Valerie's office in the Jansky Lab overlooked the parking lot, and she glanced out her window whenever she heard a car. Firsttime visitors tended to arrive very early or very late. No one's intuition about the drive was any good untU they had made the trip once. Twice cars came, and both times technicians she knew got out. A third car brought one of her grad students.

Rapt in her work she must have missed a car, because the next time she checked outside a man wearing a suit and tie was striding toward the building. Looking down from the second floor, she could not see his face, but it had to be Judson. No one but gowies dressed so formally, and then only on a first visit.

Scientists dressed casually. Today she wore jeans, a random T-shirt, and a plaid flannel overshirt. When the Nobel Committee called, she would shop for a dress. Maybe.

Shutting her office door behind her, Valerie bounded down the stairs. The man with the charcoal suit was in Reception, signing for a visitor badge. "Marcus?" she called out.

The man turned, and she recognized the face from last week's conversation. Judson, all right.

He had clear blue eyes, wavy black hair (at the moment wind-stirred) gone gray at the temples, a strong jaw, and, despite the early hour, hints of a five o'clock shadow. A bit guarded in his expression, perhaps, but fair enough: She had been less than forthcoming. Forty or so, she estimated. Not Hollywood handsome, but handsome enough. Not that that mattered. He was about six-two and broad-shouldered. Maybe a few pounds over his ideal weight, but he carried it well. Other than overdressed, he seemed, all in all, like an everyday sort of guy.

"I'm Marcus," he agreed, extending his hand. "Hello, Valerie."

"Thanks for coming." She hesitated. This was a person in front of her, not some bureaucratic abstraction.

But neither were powersats abstractions.

"Valerie?" he prompted.

"Right." She took his hand, casting off her doubts. "Welcome to the National Radio Astronomy Observatory, NRAO. We'll start with a tour. The things we need to discuss will make more sense with some background."

"What else have you planned?"

"The weekly technical lunch discussion among the professional staff, always fascinating, and we'll wrap up with

a quiet conversation in my office." A long and pointed conversation.
"Okay. Lead on."
Following her outside, he seemed surprised at her beat-up old Volkswagen Jetta.
"Because it's a diesel model," she explained. "We only take bikes and diesels near the dishes. Anything else would mean RF from spark plugs or electric motors. And the older the car, the better. New cars have electrical everything, from locks to clocks to seat positioners. Makes them noisy."
"The instruments are that sensitive?"
Wait till you see the dishes up close, she thought. A short drive brought them to the internal gate. She got out of the car to swipe her ID badge through the reader. Just past the gate, she pulled onto the shoulder. "That's one of our smaller telescopes. Forty-five feet across."
"I know. I walked around for a bit."
"How far did you get?"
"Half past Saturn before I turned around. Any farther and I would have been late."
She pulled the Jetta onto the shoulder near each telescope to share some of its background. Near one dish, bikes leaned against a trailer: the mark of grad students at work. She took Marcus inside the cramped maintenance trailer for a peek at the equipment - and at the quarter-inch steel walls shielding the dish from the electronics.
Back in her car, as she started to describe the first eighty-five-footer, the Science Center's white diesel tour bus lumbered past, "This is part of a three-telescope interferometer. An interferometer -"
"Synthesizes data from multiple instruments into one image. The composite has the resolution of an instrument the size of the separation between instruments. Same principle as synthetic aperture radar. " He grinned. "I'm an engineer, and I come prepared."
Valerie knew the former. She had hoped for the latter - and that he would be openminded. Only then did it occur to her to ask how open-minded she was.
It was not the time to second-guess herself. And anyway, he would get much the same message from many of the staff. All the more important that she get him to lunch on time. . . .
"Let's skip to the main event, " she said. Because the big dish will knock your socks off.
When she next parked, Marcus, his eyes round, rushed from the car. Everyone did. She gave him time to take it all in: the world's largest birdbath, atop an intricate lattice pyramid, above a round trolley base with sixteen enormous wheels. In addition to a standalone trailer, a built-in shielded room high above the ground held many of the onsite controls. The instrument arm, jutting out from and over the dish, made the telescope that much more impressive.
"The Green Bank Telescope," she began, pointing up at the enormous paraboloid dish. "Completed in 2000, the GBT replaced the smaller big telescope that collapsed under its own weight from metal fatigue in 1988. The dish's signal-collecting surface measures one hundred meters by one hundred ten meters - longer in both dimensions than a football field. Only that's not a surface, but 2,004 small aluminum surfaces. Automation tilts and warps each panel in real time as the structure moves, to compensate for sagging, thermal grathents, and wind."
"Damn, that's big. What happens if lightning strikes?"
"It happens about four times a year, without incident. The GBT weighs more than sixteen million pounds, about the same as nineteen loaded and fueled jumbo jets. When lightning does strike, that's a lot of metal, with all its metal wheels firmly pressed against the well-grounded steel track. The track is lots of metal too: a circle sixty-four meters in diameter."
She resumed her script. "When tipped such that the instrument arm reaches its highest position, the GBT stands taller than the Statue of Liberty. This is the world's largest fully steerable radio telescope."
Hand to his forehead, shading his eyes, Marcus countered, "Surely Arecibo is bigger."

Because everyone knew the observatory at Arecibo, Puerto Rico. Filmmakers loved it. The first time she remembered seeing the Arecibo dish was in some old James Bond flick. Goldeneye, maybe.

Arecibo's dish was three hundred meters across, its aluminum panels suspended over a mesh of steel cables to form a single surface: way too massive to move. To aim the Arecibo telescope - to the extent it could be aimed- you positioned its suspended instrumentation module using the cables that spanned the dish. None of which mattered. If she failed, Arecibo would face the same problems as Green Bank.

Valerie limited herself to, "Bigger, but not fully steerable." She pointed at the GBT's base, where the mammoth wheels engaged the circular steel track. "As opposed to our big scope. This whole structure can rotate up to forty degrees a minute, versus one-fourth degree per minute needed to keep pace with Earth's rotation. The dish can tip up and down at as much as twenty degrees per minute. That instrument turret at the end of the arm holds up to eight independent instrument modules, each-"

"Back up, " Marcus said. "Those tipping and turning rates. You're telling me that the GBT can track planets, asteroids, even close-orbiting satellites. Stars and galaxies only move with the Earth's rotation. " She must have looked surprised because he added, "Remember who I work for?"

"Right. And sorry."

"Except asteroids and most planets don't emit radio waves. In the middle of the quiet zone, where my cell phone has no service and NRAO won't even permit digital cameras up close, I can't believe the observatory is pumping out radar pulses so you can read the echoes. "

He was quick, which was promising, and he seemed engaged in what she'd had to show him. But around the eyes she saw a touch of . . . something. Suspicion? Was she that transparent, or was it something else?

"You're correct," she said. "Arecibo transmits and Green Bank reads the faint echoes. We could transmit ourselves" - she pointed up at the instrumentation arm- "by replacing one of the receiver modules with a transmitter, but that would hardly be radio quiet. My work involves the radar mapping of Titan, and we partner with Arecibo to do it."

"Titan? Just how sensitive is this scope?"

"If there were a cell phone on Titan, with the GBT I could listen to the call." Barring other complications, and that topic was coming. "We need to move along, Marcus. The weekly science lunch is not to be missed."

Especially because you are on deck.

Patrick Burkhalter toted his cafeteria tray to the residence hall's second floor, where he found the social lounge half filled. Many of his colleagues were already seated and eating. Others surrounded Valerie Clayburn and her guest, meal trays in hand, intercepted before they could find a table. With maybe eight thousand people in the entire county, everyone welcomed new faces. But visitors and outsiders comprised very different categories, and after eight years here Patrick remained an outsider.

"Hey," he offered as he took an empty seat. Tamara Miller glanced his way, nodded, and went back to her conversation with Liam Harris. Something about intergalactic dust.

Patrick went to work on his country-fried steak, mashed potatoes, and gravy. His choices would do nothing for his waistline or his cholesterol, but who did he have to impress?

Or to live for? That was a thought depressing enough to make him set down his fork.

Their guest got perhaps two minutes with his lunch before Valerie began tapping her water glass with a butter knife. "Hi, everyone. We have a visitor, as you may have noticed."

Not to mention that she had put out the word to make sure the tech staff all came today. Would she get the outcome for which she so obviously schemed? In Patrick's experience, manipulating scientists and engineers worked about as well as herding cats.

"Hello," the chorus rang out raggedly, from around the collection of short, narrow tables arrayed in a U.

Valerie said, "Our visitor, Marcus Judson, works at NASA Goddard on the demonstration powersat project. I'm hoping he'll tell us about it."

Patrick refocused on his lunch while others murmured their encouragement.
Judson kept his response short, and Patrick approved. You didn't know you were today's featured attraction, did you?
"So what do you think, folks?" Valerie prompted. "How will powersats affect us here?"
And the games began.
"A powersat is a huge noise generator, " Aaron Friedman said. "And because it's skybased, that's noise from which we can't hide."
"The power beam is focused." Judson slid away his tray, the meal all but untouched, clearly perceptive enough to see what was coming. "The downlink won't come anywhere near here."
"Doesn't matter," Aaron persisted. "Well, aiming will help, but not enough. The satellite shapes the beam with phased-array techniques, right? So there are unavoidable side lobes to the main beam. That's basic math. Even sixty dB down, there'll be a lot of noise."
Engineers and astronomers set aside lunches to argue about phased arrays: their pointing accuracy and failure modes, die frequency distributions apt to show up within the noise, and whether sixty decibels was the expected attenuation for a side lobe. Of course even sixty dB down from one gigawatt left a kilowatt of noise.
Judson kept thanking people for their comments. Mostly he let the staff argue among themselves, jotting notes on paper napkins- and looking ticked off.
This was not a mugging, exactly. More like an intervention, or maybe an inquisition. When Patrick tried to catch Valerie's eye, she looked away.
Patrick knew all about inquisitions by die tech staff. That had been his introduction to Green Bank, too, if for a different reason. Judson would go home with only bad memories to show for the day. Whereas he . . .
He still bore the scars. Patrick was more ttian qualified to coordinate routine maintenance and teach visiting astronomers to operate the gear, so it hadn't been entirely a pity appointment. More like an I'll owe you one arrangement between execs at the apex of Big Science.
After the Jules Verne probe went missing, JPL wanted Patrick gone. NASA did, too, but even more, they wanted to put a halt to the embarrassing publicity. No matter what anyone suspected, they could only prove that he had cut procedural corners to upload an emergency maneuver. That die distant probe went silent days later could have been pure coincidence.
And so Patrick had made clear what would keep him from giving interviews and suing for wrongful termination. He required ongoing access to a big dish - somewhere.
Without too much torture of the English language, Green Bank was somewhere.
And so he went in one not-so-easy step from the principal investigator of a major interplanetary probe to lowly observatory staffer. Training and maintenance offered plenty of opportunity to use radio telescopes without grant applications sure to be rejected.
He used the big dishes every chance he could get.
After the divorce- no way would Anna move here from Pasadena - what else did he have to do?
He had sworn to Anna that things would turn out all right. That maybe this had happened for a good reason. He would not have trusted him, either, especially given how little he had been able to explain, but it still hurt diat she hadn't. More than anything, he missed the kids. He wondered if Rob and Clarissa would ever understand, or forgive him for the divorce.
When Patrick tuned back to the present, Judson remained in the hot seat. Only the objections varied: from powersats, miles across, getting in the way of observations, to the heat they would reradiate as infrared, to minutiae of RF interference. Some people argued for the joy of arguing. Par for the course here, but Judson could not know that.
Along the way, an admin slipped into die lounge and handed Valerie a folded sheet of paper. Another joy of life in the quiet zone: runners instead of cell phones. Valerie grimaced at whatever she found written, dashed off

her own note, and handed it to Judson, then rushed off.
By the time the hyperbole reached, "Powersats will mean the end of astronomy until" - yeah, right! - "someone builds an observatory on the far side of the moon," Patrick had had enough.
"There's more to life than astronomy," he snorted. Too bad Valerie had left. If anyone needed the reminder, she did. But for Simon, she might never go home. "And life takes power, people. Lots and lots of power."
Turning, Tamara gave Patrick an Et tu, Brute stare, but from across the room a couple of engineers nodded.
"We learned to live with DirecTV," Ernesto Perez conceded.
To which someone snapped, "Yeah, by giving up listening on those frequencies."
Rekindling the debate, from which it took the tech director noisily sliding back her chair to bring a halt.
At least, Marcus thought, tucking his notes from the lunch into his shirt pocket, one secret of the Universe had been revealed. Town meetings were not the worst way to spend a day.
If he had correctly parsed Valerie's scrawl, she was retrieving a sick kid from school and going home for the rest of the afternoon. One scribble might have said "single mom," to explain her disappearance. It was too bad about her son, but Marcus was happy to make a quick getaway.
Only driving home, as much as he tried to enjoy the Appalachian scenery, he couldn't. Ellen's recent rebuke kept nagging at him: Have you considered the possibility someone else might know something?
If he could get past Valerie bushwhacking him, she had given him a lot to ponder.
Wednesday, April 19
Marcus poked at a telecom console, setting parameters for the upcoming conference call, and thinking: all meetings are not created equal. He was in a mundane conference room at Goddard, deep within suburban Maryland, but this call was out of this world.
Whatever grief the week might bring him, the progress review reminded him why everything else was worth it.
Landscape undulated over the conference table, sliding past as a distant camera swiveled on its post. Somewhere behind the camera, the full moon was about to set; Phoebe's hills and structures cast long, knife-edged shadows. To his right, in the tourist bot preserve, the Grand Chasm gaped: a vast, inky blackness. The dazzling "star" just above the eerily close horizon was The Space Place, almost two hundred miles ahead of Phoebe in its orbit.
Ellen limped into the telecom room, bearing Starbucks. Despite physical therapy, her leg still bothered her. She set a cardboard cup on the table beside him.
"Thanks," he said, concentrating on the final link left to configure. "That said, you have no respect for tradition. "
She laughed. "Okay, who confirmed for today's session?"
He gestured at the holo. "The usual folks on the far end, though Dartene Stryker is at the powersat. She'll call in from there."
"How far is the far end today?"
As distant as it could be. "As the neutrino flies" - right through the Earth, without noticing - "it's about thirteen thousand miles. Relayed through two geosynch comsats and then down to Phoebe, call it a half second."
She closed the door and settled into a chair. "Who's joining from on the ground?"
"Phil and Bethany." Phil Majeski was the prime contractor's program manager. Bethany Taylor was Phil's chief engineer. Both disdained SETA contractors. "Phil's netting in from corporate. Bethany called to say she's stuck at a subcontractor's facility. Resetter picketing, unrelated to us- something about shale-oil gasification in Wyoming. I'm linking her in now." Marcus waved a wireless key fob at the sensor in the comm console. The authentication LED blinked green. "Ready."
"Let's go."
Marcus shrank the Phoebe image to one-fourth size, then switched views from the surface to the base's little common room, where three men sat waiting. As they and Ellen swapped greetings, Marcus connected the other locations.

"Everyone have the agenda?" Ellen asked. She started through her list.
The comm console took notes, but speech-recognition software glitched under the best of circumstances. These weren't. Merely this many people in one conversation sometimes confused the software. With the comm delay between Earth and Phoebe, people spoke over each other as often as not, and echo suppression was less than perfect. Noise suppression filtered out the drone of Phoebe's ventilation fans, but not the random clatters of- well, Marcus did not always know what.
So Marcus took notes, too.
Lots of notes. Hydroponics yields in Phoebe's still experimental gardens. Performance data on the thrusters that would slowly lift the powersat, its construction now almost complete, to its operational orbit. Final integration tests on the microwave transmission arrays. Production data on Phoebe's automated factories, churning out solar cells (and in smaller quantities, other electronics), structural beams, and water and oxygen for the construction crew. Defect and repair rates. Assembly anecdotes - but not many, the process having become routine. Assembly statistics.
PS-I had just topped two million pounds! How amazing was that? The late, unlamented International Space Station had massed only about one third as much, and its on-orbit assembly had required more than a decade. But the ISS had been lugged up to orbit piece by piece, battling Earth's gravity all the way - for more than a thousand dollars for every pound. For a powersat fabricated on Earth, launch costs alone would rival construction costs for a coal power plant of equivalent capacity.
But most of PS-I 's ingredients came from Phoebe's mines. And that was why- while there would never be another big tin-can space station - tens of powersats would join PS-I. Even combined, all those powersats would scarcely touch Phoebe's trillion-ton mass.
Motion in one of the four holos kept drawing his eye. Darlene Stryker, in her skintight counter-pressure suit. She floated above the vast plain of the powersat, the nearest safety-and-inspection camera following her as she drifted at the end of her tether. As the camera tracked her, coworkers - most many-tentacled robots, one human and space-suited like her- passed in and out of the background. He did not see any of the hoppers that shuttled workers the fifty miles from Phoebe to the construction site on the powersat.
Two million pounds was an abstraction. But two miles square, more or less: that was real. That he could feel. Marcus admired the plain of solar cells aglitter in the moonlight. PS-I seemed to stretch on and on forever.
"Okay," Ellen said at last. "Good session, folks. Bethany, I'll look forward to your update on getting the backup water recycling system back to nominal. For next week's meeting?"
"No problem," Bethany said. "Chances are you'll have something in your e-mail by the day after tomorrow. "
"Excellent." Ellen stood. "That should do it, then."
"One thing," Marcus said. The words just popped out. Something about PS-I stretching into the distance. Something about defects, and big engineering, and his subconscious at work.
Phil Majeski scowled, putting his whole face to work: brow furrowed, eyes narrowed, lips pursed. Phil was no fan of support contractors.
"What is it, Marcus?" Ellen sounded surprised. He usually held any comments until after the meeting.
What indeed? Big engineering. What else was big? The solar farm he and Ellen had toured. Square miles there, too, of solar cells, plus the rectifying antennas newly added to receive the microwave downlink from PS-I. The Green Bank Telescope, the collection area of its dish a "mere" two-plus acres. Eavesdropping on phone calls out near Saturn.
Then he had it: the flip side of the powersat, from this vantage unseen. The microwave transmission arrays. No one had ever deployed such a large phased-array transmitter, whether using solid-state masers or tube-based amplifiers coupled to microwave antennas. Nothing ever built even came close. PS-I incorporated both types of arrays, each in several design variations. The separate arrays would operate standalone or in unison, allowing side-by-side comparisons. In every case, many thousands of transmitters . . .

"The failure rates on the klystrons and masers?" Marcus began cautiously.
"What about them?" Bethany said. "We covered that. They're all testing well within contract specs."
"Understood. But when won't at least one tube or maser be out of spec? Pumping out microwaves at unintended frequencies?" Because the focused, steerable power beam resulted from exactly controlling- individually and in real time - the many thousand transmitters. The math of phased arrays was a thing of beauty, the choreography of constructive and destructive interference among transmitters. Only waves at the wrong frequency would not interfere properly, would not aggregate into a controlled beam. Wrong frequencies were just . . . noise. "A single misbehaving klystron- out of thousands- is like a whole TV satellite transmitting on an unauthorized frequency. "
"Which is why," Bethany snapped, "when a klystron goes out of spec, we'll power it down. Powersat-resident maintenance robots and spare parts, remember?"
And if, in the meanwhile, the interference obliterates an interstellar observation years in the planning, or the faint echoes of a radar beam bounced off Titan?
"Maybe the radio astronomers have a legitimate concern," Marcus said. "How soon will PS-I detect and adapt to an out-of-tolerance transmitter?"
"Soon enough," Bethany came back, only without her usual cockiness.
Ellen heard the uncertainty too. "As I recall, Kendricks signed up to a requirement to minimize RF interference with ground-based systems."
"We all have a schedule requirement, " Phil rebutted. Schedule was the blunt instrument with which Congress beat up NASA, and NASA the contractor. But deadlines could work both ways. "Surely schedule takes precedence over hypothetical failure modes."
"And suppose that such a hypothetical failure occurs?" Ellen persisted. "What operational tests do you have planned to demonstrate PS-I 's corrective action?" Pause. "Marcus, would you check that for me?"
"Sure, Ellen," Marcus said.
He was all but certain that the test-case database contained nothing relevant. And that Kendricks's award fee for the calendar quarter would take a hit if Ellen wrote up the finding as a critical deficiency. And that Phil, who as the Kendricks program manager got a slice of the award fee, would share die pain.
Phil sighed. "It won't be necessary, Ellen. Transmitter failure and response sounds like another set of simulations we should run. "
"And also," Marcus added, "simulations with randomly spaced pairs of transmitters gone rogue at the same time." Twisting the knife, but also being practical. "Dealing in such large numbers, two near-concurrent faults are bound to happen. "
Because what the hell. Phil hated him anyway.
Toe tapping aimlessly (and occasionally kicking the ethernet cable), Valerie pondered an empty screen. She was so tempted to roll up her datasheet, but at week's end the application window closed for observing time on the big dish. Miss the cutoff- or fail to make a strong case- and she would have to wait four months to reapply. She and a few hundred other needy applicants.
By her side at the dinette table, Simon worked on a school assignment. Or, to judge from his fidgeting, not. At least while she sat there, the IM window on his datasheet remained closed. "How's the assignment coming?" she asked.
He countered with, "What's for dinner?"
Not encouraging while Simon still toyed with his midafternoon snack, and with a big stack of homework due the next day. "Want me to take a look? Need some help?"
"Nah." Fidget, fidget.
She looked anyway. The top window in his datasheet was a social studies unit called The Great Oil Shock. There had been, she read furtively, "an unexpected drop-off in production among some of the world's largest oil

suppliers." Very PC: Something had happened. Not something anyone caused to have happened.
Not that she would want to try explaining the Crudetastrophe to a nine-year-old, but it was no mere "drop-off," and someone had most definitely caused it. Even though who, and what had happened October 12, 2014, remained a closely held secret of the Restored Caliphate.
But far more was known than the sanitized children's lesson Valerie was surreptitiously slamming. . . .
Oil prices surged in the weeks following Simon's birth. Valerie scarcely noticed, let alone registered that the jump supposedly was a big deal. With a colicky newborn to care for, who had time to sleep, much less to surf? Or, for that matter, to drive? She had nowhere to go for the next few months, and work, when she did go back, was in biking distance. And hallelujah for teachers: Keith had the summer off too. If the world chose to have a crisis - and when was it not on the verge of one?- she figured the world could muddle through without her. And, anyway, didn't energy prices yo-yo every few years?
The world did have a crisis without her.
That August the Caliph's Guard declared to the world that it had deployed atomic devices deep within the country's main petroleum reservoirs. To deter aggression by its enemies - variously: counter-revolutionary elements, apostate neighboring regimes, the Zionist entity, and hostile Crusader powers - the Guard vowed to deny their oil for all time if blasphemers impinged on the Caliph's holy sovereignty.
Still, she scarcely noticed. Simon was all of three months old. Keith was up to his eyeballs in last-minute lesson plans. After two years as a substitute, he had just gotten an appointment to teach economics at the Pocahontas County High School. She and Keith both struggled to make childcare arrangements so she could get back to work at the observatory. The scattered few minutes she could spare from family, if only to clear the cobwebs from her brain, she spent poring over the latest exosolar planet surveys.
If none of that had been happening in her life, she still would not have understood what insanity drove the Guard to trigger its nukes. To this day, perhaps no one knew outside the regime's inner circles. And maybe not even them. After the explosions, Guard factions had turned on one another, and on foreigners, in an orgy of blame, purges, and executions.
But however mysterious the Crudetastrophe's origins, its consequences were all too clear:
- Radiation tainted petroleum reserves measuring in the billions of barrels, the contamination spreading into neighboring states' oil fields. Whether the reservoirs were always linked deep underground or the atomic blasts had opened fissures between once distinct reservoirs - experts disagreed - petroleum exports abruptly ceased from across a wide area.
-Regional antagonisms erupted into open warfare.
-Oil-field destruction and shipping blockades spread far beyond the Restored Caliphate's borders. Economies collapsed across the Middle East.
-The price of petroleum tripled.
The supply and price shocks plunged most of the world into deep recession. Unlike the oil embargos of 1967, 1973, and 1979- their extent and duration limited, ultimately, by the suppliers' dependence on oil sales - the Crudetastrophe was irreversible. Many onetime exporters could not resume production as fervently as they wished to.
China's and Japan's export-driven economies collapsed further and faster than most. Almost overnight, China and Japan were selling U.S. treasury bonds rather than buying them. Interest rates soared, currencies deflated, and countries reneged on their debts.
Stagflation, Keith said. Stagnation and inflation together.
Nine years later, The Great Stagflation still raged. But not everywhere -
The Crudetastrophe explosions had not affected Russia's vast oil and gas reserves. Russia emerged from the crisis as a petro-superpower, controlling unprecedented wealth, snapping up American treasury bonds at firesale prices, and vying for global economic hegemony.

And as chaos spread across the Middle East, Keiths Marine Corps reserve unit was called up ....
"Mom. Mom. Mom!"
Valerie shook off the old, sad memories to find Simon squinting at her suspiciously. "What is it?"
"What is for dinner?"
She was in no mood to cook. "Frozen pizza." As Simon beamed approval- not exactly a compliment to her culinary skills- the phone rang.
Life without cell phones was liberating. But only corded phones? Shaking her head at the primitiveness of it all, Valerie took the three steps to her ancient, corded landline phone. Simon was squirrelly today. If she took the call on her datasheet he would be out of his chair like a shot to mug for the webcam.
"Valerie?"
She could not place the voice. "Yes?"
"Marcus Judson." Pause. "Is this a bad time?"
In hindsight, she had not handled his visit very wisely. It was hard to imagine this call ending well. "Now is fine. What's up?"
"You and your cronies gave me something to think about. And the thing is . . . you're right. There might be a problem. "
The well-stretched cord would reach well into the dining room. She went; Simon followed; she shooed him back.
"Your assignment," she mouthed. "Go on, Marcus."
"It's not like I think we should stop work on the powersat, but there could be complications. There might be problematical failure modes we need to work around. " When he started explaining phased arrays to her, she interrupted. "Remember who / work for?"
"Touché." He coughed. "I meant to ask, Valerie. How's your son feeling?"
"Thanks for asking. Simon has progressed to the malingering stage." And unless he is bleeding from the ears in the morning, he's going back to school.
"Okay, here's the thing. We never had our one-on-one discussion, and I'd also like to collect input from specialists there to fold into a failure-mode simulation. What if I come back out, say, Friday the twenty-eighth?"
"That would work." But there was something else in his voice. A hesitance. He wouldn't. Would he? "Was there something else?"
"Yeah ... I wondered if I could take you out to dinner afterward. "
Crap, he would. She hadn't dated but once or twice since Keith thed. For the longest time, she hadn't been ready. After, Simon and work consumed her time. Anyway, she was content with things the way they were. Or was it resigned?
Had she wanted to, who was there to date, anyway? Coworkers? Uh-uh.
If she told Marcus no, then what? A sudden loss of interest in radio astronomy? He did not seem like the punitive type. Hell, she had sandbagged him. Maybe he meant only a dinner of colleagues.
As her thoughts churned, the silence stretched.
"Or not," Marcus said. "I thought we might hit it off, but maybe you're seeing someone. Or whatever. Forget I asked. It has no bearing on my returning to Green Bank. I do need to talk with the experts."
"No," Valerie said, surprising herself, "asking is fine." Reassuring which of them? "And dinner does sound like fun."
Friday, April 28
Astronomers, engineers, and programmers wandered in and out of the Green Bank social lounge, where the atmosphere was more like an after-hours bull session than an inquiry. For long-scheduled observing time or to handle other commitments, Marcus told himsetf every time someone left. But despite the informality- or, perhaps, because of it- the notes file on his datasheet grew voluminous. His fingers ached from so much typing on its virtual keyboard. One thing this gathering was not: a DC-style, stultifying meeting.

Phil Majeski's simulation team would have its hands full in the coming weeks.
Valerie Clayburn was among the nomads, leaving Marcus to wonder how they would synch up for dinner. Whenever she popped in he treated her like anyone else - this was work, not a date, and her coworkers were all around, too - while second-guessing himsetf whether he was being too distant.
Why, but for a getting-back-on-the-horse-that-threw-you theory, had he asked her out?
Because Lindsey - the horse who had thrown him - was three months gone. Because life went on. Because Valerie was smart, intriguingly intense, and, despite her apparent efforts not to show it, hot.
"... until they're in the way. "
They? Marcus had let his mind wander. Again. "Say that again?"
"Are we going too fast?" Tamara Miller asked. "Moving targets. How will we know where they are until they're in our way?"
Going too fast would serve as an excuse. Marcus opened a datasheet window for the auto-transcription function. With everyone chiming in at will, the voice-recognition output was half gibberish, but half was more than he had processed over the past few seconds. He skimmed. Aha. Migration.
All powersats, not just PS-I, would be built near Phoebe and its mines and factories. After completion and checkout, the powersats would be boosted - slowly, because tiiey were so massive - to their final destinations. In geosynchronous Earth orbit, GEO, tiiey would be all but stationary overhead.
"So your concern," Marcus inferred, "is the trek to GEO, with the powersat's orbit spiraling out till it arrives. "
Tamara nodded. "Yeah. How will I know when and where it's going to get in my way? Or maybe they, if there may be more than one powersat migrating at once."
"Not just us," Valerie said, back again. "Optical astronomer, too. And pity the poor Earth-based infrared astronomers. A structure that's miles square soaks up a lot of sunlight."
"Kind of the idea," Marcus said, getting laughs. "But I see your point. You need a way to plan around the powersats even before they settle into geosynch. I can recommend an Internet application anyone can access for tracking and orbital predictions. And real-time position, too, as determined by GPS. Okay?"
"What about flight plans?" Tamara countered. "Shouldn't powersats be in FAA files?"
Marcus took notes. "Probably a good idea." And around Phoebe and The Space Place, essential for safety too.
"Real-time access," Ernesto Perez added, "so we can input the powersat orbital predictions into our scheduling software."
When Valerie disappeared again, around four p.m., Marcus tiiought maybe she had left to change clothes. (He planned to change, but after his first visit he had known to leave coat and tie in the car.) When she reappeared half an hour later, though, she still wore the same blue jeans and tan sweater. Even in sneakers, she was almost his height. He guessed she was about five foot ten.
She could wear a flour sack and be gorgeous. As for his coat and tie, they could stay where they were.
Five-ish, Aaron Friedman left with a parting shot of, "See you later, Valerie."
Marcus waited for her to correct her colleague. She did not. He thought he had asked Valerie out. On a date. Had "can I take you out to dinner?" somehow changed meanings during his time with Lindsey?
Shit, he was not ready for this.
The two of them finally had the lounge to themselves. "Ready for dinner?" he asked.
She smiled awkwardly. "Sure. That'll be nice."
"I'll need you to suggest someplace to eat."
"Not hard." She smiled again, and this time it came across more sincere. "We don't have many to choose among."
They headed in his car for Durbin, only slightly less tiny than Green Bank. Instead of making get-acquainted chat (not that he seemed to remember how), he focused on the narrow, twisty roads. The ten-mile, thirty-minute drive took most of his attention.

Unless dimness counted as décor, the family restaurant and bar had none. Several people he recognized from today's meeting, including Aaron Friedman, occupied stools at the bar. Banter with the bartender suggested they were regulars. That was one mystery solved, anyway. As for Valerie's expectations for the evening? Time would tell.

Compared to the afternoon's free-for-all, the conversation once he and Valerie were seated felt stiff. His scars were too fresh. Her scars, whatever they were, seemed to run deeper. He called it a toss-up who felt more ill at ease.

Ruling out shoptalk might have been a mistake. What did people talk about on first dates? He couldn't remember. The short menus, when the waitress brought them by, offered few possibilities to eat or discuss.

"How old is your son?" he asked as they waited for their appetizers. "Simon?"

Getting the name right got him another of those too-rare natural smiles. "Simon. He's nine. Precocious guy, in a mischievous kind of way. Reminds me . . ."

Of his father, Marcus filled in the blank. It felt too soon to ask. All he came up with, gracelessly, when enough time had passed was, "What have you read recently for fun?"

She named two novels he had never heard of, but he asked about them anyway. The waitress arrived with their entrées and the conversation trailed off again. This evening was a disaster.

Valerie told herself she should be home with her son. Only she knew that for a lie: Simon did just fine with babysitters, had more or less adopted Brianna as his big sister. Lying to yourself is never a good sign.

Her head was not in the game.

She found little to say when Marcus asked about favorite movies and music, or volunteered his own. When he launched into gadgets-about which, as an engineer, he was predictably enthusiastic- she shot that down too. Sorry even as she said it, she disgorged some inanity about devices that would not function in the quiet zone or were a pain tethered to an ethernet cable.

And when he unintentionally brought Keith to mind, she shut down even more.

She should have asked around about first-date topics. Clearly, she would not need to ask about second dates.

"Will you excuse me? I should check on Simon," she said.

"Sure." Reflexively reaching for his cell, Marcus laughed at himself. (She liked that in a guy. Too bad she was such a failure at this.) "I guess the restaurant has landlines you can use."

"For regulars, the house phone. It's behind the bar." She stood. "I'll be right back."

She found Patrick Burkhalter holding down a barstool. The rest of the Green Bank regulars appeared to have left.

Patrick must not have shaved that day. She thought he had worn the same pants and shirt the day before. He was heavier every time she saw him, his clothes tighter, his gut bulging over his belt. The mound of buffalo wings in front of him would do nothing to reverse the trend. And he drank alone far too often. Poor guy: No one to go home to.

"How's the big date going?" Patrick asked her.

"Just colleagues," she said. After the fact, if not by original intent. "Hand me the phone?"

To judge by the giggling in the background when Brianna answered, Simon was doing fine.

Patrick was nursing a beer with one hand, prodding his datasheet with the other. An ethernet cable snaked behind the bar from the datasheet. Something about Patrick tickled at the back of her mind.

Damn! Maybe she had gadgets to share after all. And they were wireless in a big way.

Black, sterile landscape hung in a shallow arc before Marcus. Up close, churned ground. In the left distance, a range of low hills. Straight ahead, receding into the distance, a pockmarked plain. In the right distance, rippled terrain that blended into more hills.

Phoebe, as he had never experienced it.

He and Valerie sat side by side on her living-room couch, an ordinary game controller in front of each of ttiem

on the coffee table. "What do you tiiink?"
Marcus hardly minded being invited inside after dinner - but he was more than a little surprised. She had insisted she had something to show him. What was this about? "Interesting," he offered neutrally.
"Give it a shot," she said.
He glanced down at his game controller. Landscape shifted as his head moved. Infrared laser beams shining into his eyes and sensors tracking eye motions from the reflections. He looked up and the landscape shifted again. "The hills to my extreme left and right look alike."
"Identical, in fact. The bot's full-circle view is compressed into ninety degrees, because you, unlike the bot, can't see three-sixty. To your far left and far right, about ten degrees of landscape overlap for continuity. You get used to it."
Marcus had never seen the attraction of the Phoebe tourist bots. Moon bots, maybe. Over the years robotic lunar landers had deployed those to far-flung and quite varied terrain. The catch was cost: Lunar bots were expensive. Once an armchair explorer sent a lunar rent-a-bot over a cliff or into a crevasse- that was that. And because of the comm delay to/from the moon, accidents did happen. And so, time on lunar bots did not come cheap.
Lose a bot on tiny, nearby Phoebe- much less likely, anyway, given the shorter comm delays - and often someone could retrieve it. Recoverability made armchair exploration of Phoebe affordable.
But Marcus "saw" PS-I and Phoebe almost daily, with clearance to operate the surfacecamera systems. (Not bots, though. For security purposes, work bots could only be accessed with much higher clearance than he had, and then only from local terminals.) He had come to think of the rent-a-bots creeping about parts of Phoebe's surface - when, from time to time, they strayed outside the tourist zone - as so much optical clutter.
Still .. .
He swept a hand across his controller. Gesture-sensing logic read the motion - more clever processing of infrared reflections. With an all but imperceptible delay the landscape slid to his right as the bot turned. Motion somehow emphasized the duplicated scenery at the extremes of the holo.
If he recalled correctly, and the fast response suggested he did, Phoebe was all but overhead at the moment.
He swept his hand back - and nothing happened.
"Hold your fingers together," Valerie said, "so you don't clutter the IR reflections. Fingers don't control individual tentacles."
Walking by gesture would be a great user interface. If his hand had eight opposable fingers. If the round-trip delay, ping-ponged through comsats, though far more manageable than in the lunar case, did not sometimes approach a full second. "Walking" involved a joystick and then only indicated a general direction. The bot's onboard nav software figured how to locomote across the landscape.
He swept his hand again, keeping his fingers straight, still, and together. This time, the landscape shifted as he expected. "I don't get it. Exploring Phoebe seems like the last thing that would interest you."
"Patrick, a guy I work with, was into these bots right after Phoebe rentals came online." She seemed about to say more, and to reconsider. "I tried to interest Simon in remote-controlled exploration. Any kid his age is going to spend time in VR, and this seemed much more civilized than the usual shoot'em-ups."
"How'd that go over?"
"About as well as you'd expect. "
Marcus kept gesturing, the landscape swaying in response. "Am I ready to take a step?"
"Uh-huh. Let's find a pair of bots somewhere interesting." She did something with her controller and a translucent pop-up materialized over the landscape. "Okay, here's an idle pair of bots near the Grand Chasm. You take bot 327." With a gesture, she changed the scene.
He had seen the Grand Chasm often enough, but never like this. Never so vast. What had changed?
The horizon was way too close.

"These bots can't be more than a foot tall," he said. "I'm used to watching from the safety cameras, atop eight-foot posts. "
"Size isn't everything," she said. And blushed.
Marcus pretended not to notice, guessing the words had just slipped out. If Valerie was one for flirting or double entendres he had yet to see it.
He waggled a tentacle at her bot. "So, come here often?"
Laughing, she managed to make her bot shrug. "Only twice, both times long ago."
"Hmm. Maybe this can be our place." The line felt hokey, and yet like the first uncontrived comment he had managed all evening.
They each arched a tentacle over the raUing to peer into the abyss, where scree piles dotted the dark, undulating depths. He saw bots stranded partway down and the tentacle tips of others peeking out from beneath piles of rubble. Trapped before the barrier went up, or did tourists climb their bots over the railing?
The chasm sides looked unstable, but exactly how treacherous were they? Marcus needed several tries to grasp and drop a stray pebble over the railing. Under Phoebe's scant gravity, the rock more floated than fell. Finally, picking up speed, it struck a canyon wall and triggered a slow-motion rockslide.
Few people had ever entered the Grand Chasm, and- as much as geologists ached to explore Phoebe's most prominent feature -none had gone down very far. Too dangerous, the risk assessments always concluded. Even flying in, a hopper's exhaust could start an avalanche. Some day, perhaps, when mining was less of a priority, the staff could tunnel into the bottom of the rift.
Someday remained distant.
Marcus had long suspected an excess of caution after the early- and unrelated- incident during the establishment of Phoebe base. One geologist had already died on Phoebe, and NASA was determined not to see more.
Now, in eerie silence, as the slo-mo rockslide went on and on, Marcus reconsidered.
Only how was he seeing this? Not sunlight- ever. Not earthlight, given the minimal comm delay. Phoebe had to be more or less overhead at the moment, deep inside Earth's shadow. Moonlight? The Moon was just past first quarter. The light it cast would strike obliquely, the shadows pointing in one direction - only the shadows around the bots pointed every which way. That suggested artificial lighting, yet he saw neither lamps nor spodights.
He gave up trying to work it out. "I'm confused. Where is our light coming from?"
"Not light. Not as you mean it, anyway. The bots use lidar."
Like radar, only based on laser beams. "So this is all computer-synth imagery?"
"Uh-huh." She stood and stretched. "I feel like coffee. How about you?"
"Sure." He followed her into the kitchen, where a pair of binoculars sat on the counter near the back door.
"Wildlife?" he guessed, pointing.
"Stargazing." She finished putting up the pot of coffee and grabbed the binocs. "Come outside."
The night was cool and cloudless. After the moon, waxing gibbous as he had remembered, The Space Place, playground of petrocrats, kleptocrats, and the otiier superrich, was the brightest object in the sky. Only this was a sky unlike any he had seen in a long time. Far from big-city lights, the stars blazed. Thousands of them.
"Try these." She handed him the binoculars -
Through which countless more stars shone. And there, aglow in infrared from the residual heat of their last passes through sunlight, tiny shapes: an oval, a rectangle, and, the brightest of the three, a not-quite-round pearl. Phoebe's sunshield and PS-I, seen at a bit of an angle, and The Space Place. Phoebe itself was too dark and cold to spot even with thermal imaging.
Her hand was on his back, turning him. "Now look. No, up a little. A little higher."
"At what?"
"You'll know it when you're there. "

The Milky Way looked like spilt milk - with a scattering of diamond chips.
"Wow," he said. "Thanks." He slowly turned, taking in the grandeur of the night sky. He eventually thought to offer Valerie her binocs. To the naked eye the night now seemed blacker than ever. "It's very dark out here."
"Oh, crap!"
Huh? "What's wrong?"
"You didn't plan to drive back tonight, did you? If you think it's dark here ..."
Think how dark it will be in the forest, crossing die mountains, he completed. "Not a problem. I have a room for the night in the observatory residence hall. You don't need to chase me off just yet."
"That's good." A sudden, unexpected peck on the cheek suggested she meant it. "And if you'd like, how about you come by in the morning for breakfast?"
Turning, slipping his arms around her waist, Marcus said, "I'd like that a lot."
Monday, May 8
From the secluded anonymity of a black stretch limo, shared only with a longtime assistant, Yakov Nikolayevich Brodsky watched urban streets slip past.
He always enjoyed visiting Chicago. With its extensive expatriate community, he dined well here, on everything from Mini to borscht to stroganoff. The finest elaborate banquet cost less than a passable snack in Moscow - Because few here could have afforded Moscow prices.
And so, in a very different way he relished the signs of America's decline. The weed-choked medians. The empty stores and shuttered factories. The would-be day laborers milling about in a 7-Eleven parking lot. Most of all he enjoyed the waiting lines and pergallon prices as they passed neighborhood gas stations.
What a difference a decade could make.
The limo sped downtown amid an escort of blue-and-white Chicago police cruisers. Lights flashing, they crossed under the rickety elevated-train tracks that demarcated the Loop.
"We're almost there, sir," the driver announced soon after. "Five minutes."
A driver! How quaintiy decadent. But doubtless the driver with whom he had been provided also spied on him.
"Very well."
Yakov savored, too, Chicago's distinctive architecture. Perhaps his favorite example was the masterpiece that came into view as the motorcade turned onto Jackson Boulevard.
For decades the Chicago Board of Trade BuUding had towered over everything else in this city. From the speeding car, alas, Yakov could not fully appreciate the edifice's art deco distinctiveness. He could scarcely even see the three-story statue of Ceres, goddess of agriculture, which crowned the building's peak.
This building projected a confidence and a presence, embodiment of a bygone era, of an American century. Not so the many modern glass-and-steel skyscrapers: Their drab and boxy exteriors served only as metaphors for the hollowed-out American economy.
Police had cleared the street and sidewalk in front of the Chicago Board of Trade Building and were keeping scores of picketing protesters behind sawhorse barricades. American grain for Americans many placards read. Stop burning food another popular sign demanded.
Inwardly, he smiled.
As the limo pulled up to the curb, eight serious men and women in somber garb marched from the main entrance. Yakov waited for the driver to open his door.
"Welcome, Yakov Nikolayevich!" one of his greeters declared, a hand outstretched. "You honor us by your visit.
"
"Hello, Roland," Yakov acknowledged. Roland Johnston was chief executive officer of the CBOT. Yakov would deal with no one lesser.
"I trust your flight was satisfactory?"
"Very comfortable. Thank you." Washington, to which Yakov was posted as Deputy Trade Representative, was

only a short hop away. Shorter, in fact, than he would have wished. He so seldom found the opportunity to fly his Learjet. "My assistant, Irina Ivanovna Chesnokova."
"Ms. Chesnokova." Roland introduced his aides and hangers-on, and then, with a quick gesture toward the protest, suggested proceeding inside. "I apologize for the ruckus."
"Democracy," Yakov said. They could decide whether he intended sympathetic understanding or ironic dismissal. "Very good. I would like to see the trading floor." The pits of the original trading floor, alas, had been filled with concrete, the new area turned into mundane offices. A travesty, Yakov thought. "And the electronic trading facilities, of course."
"Naturally," an aide agreed. The corner of a folded datasheet peeked from a pocket of her jacket.
The Americans would give him the grand tour, fawn over his every word, then wine and dine him. When he completed his business, their limo would whisk him back to the airport. And between?
Between - to the certain dismay of the demonstrators outside, and countless others of similar opinion - his hosts would do everything in their power to expedite his purchase of corn and wheat. Two million metric tons of each, with intimations of yet larger purchases to follow.
They would bow and scrape and cut corners on his behalf, because he did not need their help. He could, he would suggest obliquely, shift much of his purchasing to the Canadians and Australians. His minions could quietly accumulate much of his stated need in smaller lots, through Internet trading and via pliant third parties, before anyone would see the pattern.
Only he wouldn't. Visibility, not secrecy, suited his purpose. That so rarely happened.
Ethanol substituted for gasoline. Higher grain prices made ethanol more expensive and less competitive. The mere specter of higher grain prices would spook oil markets around the globe. Whatever few extra dollars he might spend on grain- which, with great magnanimity, Russia would distribute to her friends in the Third World- would be more than repaid in higher energy prices.
Roland Johnston was by then extolling the virtues of some recent upgrade to his organization's electronic-trading mechanism.
Yakov just nodded. If anything important came up, Irinushka could summarize later for him. She had already asked several probing questions about the measures taken to assure the integrity of data in their computer systems.
The men among Johnston's staff crowded around her, drawn to her classical beauty, vying to impress. Some must suppose she frowned in concentration at their wit or wisdom, or struggled with English jargon, for their speech had gotten louder and slower. And she, never giving any sign, would despise them for their vanity and condescension.
She had been born deaf. She had neither heard nor spoken until she was five, after receiving the cochlear implants masked by her long, flowing, red hair. When too many people spoke at once, or in chaotic environments like the trading floor, the din sometimes confused the implants' noise filters and speech-discrimination circuits.
Despite everything, she understood more than the fawning, self-important young men could imagine.
"Are you seeing what you wanted?" Johnston asked.
Yakov nodded. "This is a very worthwhile visit."
How strange it was to accomplish grand strategy by means as prosaic as buying corn. Because deputy trade representative was only his cover for his true position: a senior agent of the Federal Security Service.
Russia's interests often required methods more subtle - or far more dramatic,
Saturday, May 13
"What do you think, Professor?" Eric the bartender asked.
Patrick looked away from the 3-V in the corner. "I think the Yankees will win in a blowout."
Eric laughed. "That's a given. No, I wondered if you were ready for another."

It was Patrick's turn to laugh. "No, that's a given."
"I like the way you think, Professor. Be right back."
Three people sat along the bar and a few couples at scattered tables: Saturday night in Outer Nowhere. No families with children, thankfully. He still found families hard to take.
Eric reappeared with a fresh, foaming pint. "Your beer, Professor."
"Thanks." Taking a long slow sip, Patrick returned his attention to the ballgame.
He took no offense at Professor. Eric called anyone from NRAO that. In the winter, when this ski-resort bar would be hopping, Eric's patrons were "Sport." Except any ski bunnies who Eric was hitting on. Them he promoted to "Sportette."
Snowshoe was far enough from Green Bank to keep Patrick's coworkers to a minimum. Alas, because the resorts offered most of the area's finer dining, that niinimum was not zero. As, captured in the behind-the-bar mirror, the approaching man and woman reminded him.
"Hi, Patrick," a familiar voice called cheerily.
Swiveling on his stool, Patrick thought Valerie Clayburn and her NASA friend made a cute couple. Both wore casual slacks and knit shirts: dressed up for her and down for him. "Hi, Valerie."
"Marcus Judson. Patrick Burkhalter." To Patrick, Valerie added, "You remember Marcus visiting us for a staff lunch?"
The name? That, Patrick had forgotten. But Marcus himself, after the reception she had arranged for him? No way. The wonder was that Marcus had gotten past it. Hopefully he had seen through to the good person underneath. Though maybe he just had eyes in his head.
Too much information. "Of course. Hello," Patrick said.
"Pleased to meet you. You're the guy who put Valerie onto Phoebe bots, right?"
Patrick shrugged. "You make it sound like I encouraged her."
Eric sauntered over, a napkin over his arm. "What can I get you, Professors?"
"Two glasses of the house Merlot, Eric," Marcus answered.
"You've been promoted to a regular," Patrick said. And quickly: Valerie's ambush had been only four weeks ago. "Feel honored."
"Patrick is an astronomer too," Valerie said.
"Astrophysicist," Patrick corrected.
Marcus rubbed his chin, brow furrowed. "There's a difference?"
"A big one." Valerie grinned. "Say I'm on a plane. If I feel sociable, I'm an astronomer. Everyone loves astronomy. When I want to read in peace, I'm an astrophysicist.
"Marcus, I'll get us a table. Patrick, will you join us for dinner?"
Which part of astrophysicist was unclear? "I don't plan to stay late tonight," Patrick lied.
Besides, Valerie did not need a chaperone. Patrick wondered if Judson would become a regular with her too. Everyone would know when Judson stopped getting a room in the Res Hall for his weekend visits. Green Bank was a small town, and the observatory staff was even timer.
"If you change your mind, " Valerie persisted, then strode off for the dining room.
Eric ambled back, setting down two wineglasses. "I started you a tab, Professor."
"Thanks." Judson picked up the glasses, took a step away from the bar, and stopped. "Tough break," he said softly.
The Tigers had just left two men stranded on base. "Jankowski is on fire this season," Patrick said. "ERA of what, around two-nine?"
"That's not what I meant."
"Aren't you on a date?" Patrick asked. He turned, pointedly, back to the Yankees/Tigers game.
If there was one thing Patrick could not abide, it was sympathy.

Valerie slid back her plate, pleasantly full. "That was excellent."
"That was a salad," Marcus said, as though disagreeing. He had had a sirloin with a loaded baked potato, and all that remained on his plate was a sprig of parsley. Maybe only half a sprig. "How about some dessert?"
He ate like a force of nature, but if she skipped dessert so would he. "I'd split one." One bite was splitting. "What do you recommend?"
"Pretty much any of the desserts." As in: you pick. Because you studied the dessert choices before you ever looked at entrées. And because you're going to be eating most of it.
Why was dating so complicated?
"How about the death-by-chocolate cake, then. With a scoop of ice cream?"
"That sounds good." And maybe two bites.
"So, about Patrick."
She had wondered when Patrick would come up. "He's a planetary astronomer. I think you two would get along. He's not always so . . ."
"Cranky? Surly? Belligerent?"
"I was going to say gruff." The waitress came by to clear the dinner plates and took their dessert order. Valerie figured she could change topics! Patrick was so . . . sad. "Simon came home from school today with the funniest story. "
"Hold that thought. I have a question about him. Patrick, I mean. What was with the disclaimer when I mentioned Phoebe bots?"
"Honestly? I don't know. It's odd. He used to rent bots quite often. But it's true that he didn't encourage me to try bots myself. "
The waitress returned with their coffees, their dessert, and two forks. Marcus moved the plate into the center of the table. "What does he do at Green Bank?"
"Mostly maintenance, and some training of visiting astronomers. With authorization you can schedule observations over the Internet, but we don't give out those codes to anyone till they've trained onsite." Three bites, she decided, taking a fork. "Do you know his history?"
"Yeah." Marcus's eyes widened with his first bite of cake. "Not the kind of incident I would forget. Ex-JPL. Broke basic ops protocol, and in the process lost a deep-space probe."
"I think that's oversimplified." She fidgeted with her napkin, searching for the right words. Patrick had confided in her, just a little, once when she had really needed the distraction. "Suppose he had gone through channels, that he had submitted a proposed maneuver. Suppose that while he waited for a review committee to approve, the spacecraft got whacked by an oncoming rock." The inward-streaking pebble that, Patrick had said, could not be found in what remained of the final telemetry after his hasty upload. "Would that be better?"
"No one second-guesses waiting for channels. " Marcus, wearing a sudden sour expression, set down his fork. "And when something was everyone's responsibility, that makes it no one's fault. Okay, I might have acted too. More carefully, I would like to think. And without wiping the comm buffer afterward to try to cover my tracks. "
"He's my friend, Marcus." And loss of Patrick's family, career, and the respect of his peers was too steep a penalty.
Patrick had been in her office the day two marines in full dress blues showed up. As Patrick had been there for her for long days after. Merely, quietly, there, not driven off, as were so many, by the embarrassment of not knowing what to say.
A good man hid beneath all that rancor. She felt Patrick's pain.
And in a rush, her own. She still missed Keith terribly. She wished her son could have known his father, taken away when Simon was just learning, stumblingly, to walk. But in an instant, a roadside bomb in Afghanistan had changed . . . everything.
What was she doing on a date?

Keith would want her to get on with her life, but she felt miserable. She tried to keep the turmoil off her face and knew she had failed.
"Sorry, " Marcus said, looking confused at her mood swing. "Are you all right?"
"Just . . . distracted."
"Do you want to talk about it?"
"No," she insisted.
Marcus took the hint. "So Patrick doesn't observe anymore?"
She wrung her napkin some more. "Not officially." Because Patrick's proposals for time on the scopes seldom got approved. "But training involves targets, and he picks the aim points. His students end up tracking lots of objects in the outer asteroid belt. "
"Outer belt," Marcus repeated. "Meaning?"
"Beyond the ice line. Distant enough from the Sun that ice doesn't melt or sublimate."
"Listening for the beacon of the Verne probe, you mean. After, what, eight years?"
"Nine," she corrected. How absurd were the odds Patrick would ever hear it? Space was big. And who knew if the lost spacecraft even still functioned? "I know. It's sad."
"Poor guy."
The waitress topped off their coffees. Valerie wrapped her hands around her cup to warm them. Not that the room was cold.
"I think I should be getting you home, " Marcus said. "You look . . . tired."
She opened her mouth, but an explanation refused to come. Dragging out the evening would not be fair to him.
"You're right," she managed at last. "Sorry."
The drive home to Green Bank continued in awkward silence. She broke it by babbling about how in I960 Green Bank hosted one of the first academically respectable SETI meetings. SETI was one of Patrick's avowed passions, and she launched into describing the transmitter module- never installed, of course - that he had designed and built in his spare time for the big dish. He often puttered after hours in the electronics shop.
Only no one she knew believed Patrick gave a flying fig about SETI, or that he had spent months getting ready to send a reply to some hypothetical aliens. What everyone understood- and no one would ever raise with Patrick- was the thing for which he did prepare: the day he detected the Verne probe's beacon. Each year, as that hope seemed more forlorn, he spent less time tinkering with the idle transmitter.
Her voice trailed off. She and Marcus completed the drive in uncomfortable silence.
They finally turned into her driveway. Light flickered in the windows, Brianna watching 3-V. Then a little figure bounded past the living-room window: Simon, wide awake. Valerie fancied she heard little-boy engine noises. The dashboard clock, as she sneaked a peek, read 8:46. She was pathetic.
"I'm sorry," she told Marcus, yet again, as he walked her to her door. "I'm not fit company tonight. May I call you in the morning? Maybe we can go for brunch. "
"Sure. I can stay till noon or so. Big meeting Monday to prepare for. "
He didn't offer details and she didn't ask. The powersat, quite accidentally, had brought them together. It would not keep them together. It was, like Keith, a subject they did not discuss.
The two unmentioned elephants in the room.
On the porch, Marcus gave her a perfunctory kiss goodnight. "Will you be okay?"
"Sure." She forced a smile. Someday.
Thursday, May 18
Slicing the tops off whitecaps, a sleek, thirty-foot hovercraft raced along the Santa Barbara Channel. In the distance, rugged and pristine, stood one of the islands of Channel Islands National Park. Santa Cruz Island, if Dillon correctly remembered the map. The sky was almost painfully bright. Sun sparkled off the waves.
"Southern California hardly counts as the tropics," Kayla Jorgenson shouted over the roar of the engine. Her tan

Dockers, starched blue blouse, and L. L. Bean windbreaker might as well have been a business suit. She had pulled her hair back into a short ponytail. Only white knuckles as she clenched the handrail betrayed nerves.
"This time of the year surface-water temperature only approaches sixty degrees, so the test bed won't reach the output levels the system would achieve near the equator. We still get a temperature differential, with respect to the bottom of the intake pipe, better than twenty degrees. The results we're measuring match our simulations quite well. That said, to unambiguously prove the technology, we would like to deploy a full-scale demo system somewhere warmer. "
If we get the money, she managed to convey without uttering the words.
Dillon tugged his cap lower. Despite RayBans and the cap's long visor, he squinted against the glare. He was a captive audience on the small boat, and Kayla was not one to waste face time. He remembered his first impression of her: focused.
They could have choppered to the demo site a lot faster, but after criss-crossing the country, flying from one cash-hungry startup to the next, Dillon had opted for sunshine and sea breezes. His face turned toward the afternoon sun, closing his eyes, he thought tanned thoughts.
He was exhausted. Already that week he had toured a lithium-ion automotive battery plant in Saginaw, a superconducting-cable company outside Chicago, a scale-model geothermal power plant in Nevada, and, only the day before, a Silicon Valley semiconductor design shop with some ideas for improving solar cells. The score so far for the week: dud, promising, dud, and scary. Cortez Photovoltaic used chemical dopants and industrial processes that made him nervous as hell. An anonymous tip to the EPA should slow that bunch for a while.
"Besides the convenient location," Kayla kept going, inexorably, "reusing the drilling rig really slashed our upfront costs. All we had to do was lower pipe, something any oil platform is already configured to do. If we extend this concept to . . ."
When Dillon next opened his eyes, the platform, which had been only a dot on the horizon, had swelled into a massive, looming construction.
Oil drilling in the Santa Barbara Channel: madness. Merely to see this oil rig filled him with rage, but he bottled the anger. He could almost wish the Crudetastrophe had tainted the reservoir deep beneath his feet.
Like the drilling platform itself, ocean thermal energy conversion was an enormous undertaking. He felt the throb before he heard it. As they raced toward the old oil platform, the pulsing grew and grew.
"You'll want these," Kayla said. Her left hand came out of her jacket pocket with two pairs of earplugs. "Anti-noise. They cancel repetitive low-pitched sounds like what our big pump makes. "
Not much use to fish, porpoises, or whales. They were screwed. One of the staff engineers Dillon had tasked to vet Jorgenson's pitch had brought up the noise issue. Her guesstimate was that underwater noise from an OTEC plant would exceed ambient levels for a good mile from the platform.
The Santa Barbara Channel was summer home to about ten percent of the world's blue-whale population. What about them?
But Kayla was right about the earplugs. The throbbing all but disappeared once Dillon had his pair in place.
She was still pitching OTEC when the hovercraft, settling into the water, coasted up to the platform's floating dock. The oil platform - an all-but-incomprehensible maze of girders and pipes, catwalks and steel plates- loomed over Dillon. High above, enormous derricks reached far out over the channel.
Twenty feet above the waves, where a spidery catwalk hugged one of the platform's massive support posts, a worker in hard hat and orange coveralls stood waiting. Projecting outward and upward, held almost vertical by taut steel cables, was what could only be a raised gangplank.
Kayla shouted out a string of numbers, and the roustabout released the brake of a winch. With a whirr of gears the gangplank pivoted and began to descend. The floating dock bucked and slued as, with a thud, the foot of the ramp struck.
"Nice drawbridge." Dillon gestured at ocean all around. "And one hell of a moat."

"We don't want uninvited guests, obviously," Kayla said. "We change pass codes daily."
As the dock's wobble dampened out, Coverall Guy loped down the gangplank to meet them. While he and crew secured the hovercraft, Dillon kept looking around. A wiremesh cage bobbed nearby, buoyed by pontoons at the corners. Peering over the hovercraft's side, wondering what the enclosure was and how deep it extended, he was startled by dark, darting shapes within. They had to be two feet long, at least.
"What are those?" he asked, pointing.
"Alaskan sockeye salmon, " Kayla said, grinning at his double-take. "Some of the cold water we've brought to the rig gets vented through the aquaculture units. That should be good for some extra income from the local seafood joints. We're thinking we might farm Maine lobsters in another cage. "
While the chilled water spewing from the rig did what to the indigenous species? Fish farming was not the insult to nature of many ventures he saw, and the shadow of an oil platform was hardly a native habitat, but still the caged salmon saddened him.
Dillon followed Kayla up the gangplank, rising and falling with the floating dock, to the lowest catwalk. From there their route was hand over hand, rung by rung, straight up the massive pillar. When they reached the bottom deck he tried not to look through the metal grating to the surging waves far below.
The next visit, if there was one, he would take the chopper!
From the bottom deck they climbed endless flights of stairs, not stopping until the helipad level. Barrels and bulky gear lay scattered across the helipad. To deter unauthorized landings? "You really don't want visitors, do you?"
Kayla just shrugged.
He grabbed his cap as a wind gust snatched it from his head. Vibrations his earplugs would not let him hear crept up his legs, shaking his entire body.
The California coast sprawled in the distance. Kayla, who had saved her breath for the long climb, resumed her spiel. "Lots of oil platforms are like this. Near enough to land for easy resupply In water deep enough to offer a significant temperature differential. Generating power by dropping pipe here is less disruptive than laying pipe from shore out to deep water."
Compared to some projects Dillon had assessed, this was environmentally sound. Sun would heat the surface waters no matter what. It would be better that obscenities like this platform had never been built, but at least with OTEC the platforms might contribute clean power.
Except that nothing built on a scale this monstrous could ever be benign . . .
"This pilot project will generate, if I remember correctly, five megawatts?" Dillon asked. "How do you deliver the power to where it will be used?"
"Converted to microwaves." She gestured across the helipad to a sturdy metal tower studded with antennae directed to points around the compass. "The smaUll dishes will beam power to nearby drilling platforms, which will no longer need diesel generators to have electricity. The big dish" - which was not all that big- "will beam to the receiving antenna under construction on Santa Cruz Island. I guess visitors at the Nature Conservancy's research center aren't ready to give up supercomputers and hairdryers.
"The microwave tech isn't much different from how the NASA powersat will transmit power to the ground, except that we aren't pushing the state of the art. We're dealing with megawatts, not gigawatts, and sent over a much shorter distance."
Powersats: The most mega megaproject of them all. If Kayla understood what mattered to Dillon- and, of course, she could not possibly - she would have picked a different example. Likening her endeavor to powersats had turned his stomach.
In her ignorance, she kept talking. "Of course not every OTEC facility will use beamed power. Where we lack a line of sight to land, and maybe for really large-scale generators, we expect to run marine power cables. You know, like the big offshore wind farms use."

And Dillon suddenly knew exactly what monkey wrench to throw into these particular works. "I have interests in a superconducting-cable start-up." Even though the bunch in Illinois did not yet know it. They had been eager enough to get some of his money.
"Zero-resistance underwater cables to the power grid on shore. Of course, that would be great." Kayla hesitated. "At the capacities we'll need, superconducting cable is experimental at best. We've got a lot on our plates as it is."
"No, this could work," Dillon said firmly. "Look, I'll put my cards on the table. One-of-a-kind investments aren't worth my time. I look for synergies, win-win situations. Here we have one. The other bunch would get an impressive, real-world demonstration. You would get first crack at a more efficient way to bring OTEC power ashore."
"Does this mean my company has your backing? That you will invest?"
Dillon gazed out across the Santa Barbara Channel, saying nothing, the breeze whipping his hair. She could do the math.
She straightened, squaring her shoulders. "If you back Jorgenson Power Systems at the funding levels we've discussed, we'll assess our fit with your other company. "
"That's all I'm asking."
Because commercializing technology of this scale would involve several more rounds of capitalization. Getting follow-on investments was all but impossible without the tangible endorsement - second-round buy-in - of the earlier investors. So: Kayla 's people would factor the new technology into their plans. Just as, when Dillon called to dangle a bit of venture capital, the Chicago bunch would swallow hard and agree to a marine deployment- desate the complexities that would introduce - for their first big field trial.
With a few million bucks of other people's money, he would tie both ventures in knots.

Test of Spanish sentences to measure speech intelligibility in noise conditions

Author: Cervera, Teresa; González-Alvarez, Julio

Publication info: Behavior Research Methods (Online) 43.2 (Jun 2011): 459-467.
ProQuest document link

Abstract: This article describes the development of a test for measuring the intelligibility of speech in noise for the Spanish language, similar to the test developed by Kalikow, Stevens, and Elliot (Journal of the Acoustical Society of America, 5, 1337-1360, 1977) for the English language. The test consists of six forms, each comprising 25 high-predictability (HP) sentences and 25 low-predictability (LP) sentences. The sentences were used in a perceptual task to assess their intelligibility in babble noise across three different signal-to-noise ratio (SNR) conditions in a sample of 474 normal-hearing listeners. The results showed that the listeners obtained higher scores of intelligibility for HP sentences than for LP sentences, and the scores were lower for the higher SNRs, as was expected. The final six forms were equivalent in intelligibility and phonetic content. [PUBLICATION ABSTRACT]

Full text: Headnote

Abstract This article describes the development of a test for measuring the intelligibility of speech in noise for the Spanish language, similar to the test developed by Kalikow, Stevens, and Elliot (Journal of the Acoustical Society of America, 5, 1337-1360, 1977) for the English language. The test consists of six forms, each comprising 25 high-predictability (HP) sentences and 25 low-predictability (LP) sentences. The sentences were used in a perceptual task to assess their intelligibility in babble noise across three different signal-to-noise ratio (SNR) conditions in a sample of 474 normal-hearing listeners. The results showed that the listeners obtained higher scores of intelligibility for HP sentences than for LP sentences, and the scores were lower for the higher SNRs, as was expected. The final six forms were equivalent in intelligibility and phonetic content.

Keywords Speech perception * Auditory perception * Intelligibility * Masking noise

The assessment of speech intelligibility plays an important role in fields such as audiology, psychoacoustics, and telecommunications, among others. The use of sentence materials to test speech intelligibility has many advantages over using other types of speech stimuli, such as words or syllables, because sentences are more representative of real everyday communicative situations than are words or syllables. On the other hand, these types of stimuli have some disadvantages. For example, if the experimenter uses different experimental conditions, such as different signalto- noise ratios (SNRs) or other listening conditions, the same speech materials cannot be repeated with the same listener.

To address this issue, Kalikow, Stevens, and Elliot (1977) developed a test of speech perception in noise (SPIN) consisting of eight lists of sentences equivalent in intelligibility and tested in different conditions of background babble noise. Thus, an experimenter can select some of these lists and use them in different experimental listening conditions simulating those encountered in everyday speech communication.

The SPIN sentences have another valuable characteristic. Each 50-sentence list contains 25 high-predictability (HP) sentences and 25 low-predictability (LP) sentences. The HP sentences are constructed in such a way that the final word can somehow be predicted by the preceding context, and the LP sentences are constructed in such a way that the final word cannot be predicted by the context. Each HP sentence has its corresponding LP sentence, so that the same final word appears in both the HP sentence and its corresponding LP sentence. The listeners must respond by providing the final word or key word. Comparing the performance of individuals on the recognition of these two types of sentences makes it possible to assess the separate effects of auditory acuity and linguistic knowledge, expressed as the capability of using the preceding context to recognize the final word. Thus, the contribution of either sensory or cognitive processing to the total score obtained by the listener can be estimated by comparing performances on the HP and LP sentences. The assumption is that the HP sentences produce higher scores than do the LP sentences, especially in adverse listening conditions. In these situations, when the acoustical cues and bottom-up processing are not enough to accomplish speech perception, top-down processing (linguistic knowledge or the use of context) can facilitate this identification.

The evaluation of speech intelligibility is especially important in adverse listening conditions that simulate everyday listening situations, such as background noise at different signal-to noise levels (Dubno, Ahlstrom, &Horwitz, 2000; Gordon-Salant &Fitzgibbons, 1999, 2001, 2004; Gordon-Salant, Fitzgibbons, &Friedman, 2007; Humes, Burk, Coughlin, Busey, &Strauser, 2007; Kalikow et al., 1977), fast speech (Gordon-Salant &Fitzgibbons, 1999, 2001, 2004; Gordon-Salant et al., 2007; Humes et al., 2007), same versus different speakers' voices (Goy, Pichora-Fuller, van Lieshout, Singh, &Schneider, 2007), or some speech distortions such as jitter (Pichora-Fuller, Schneider, MacDonald, Pass, &Brown, 2007) or noise-vocoded speech (Sheldom, Pichora-Fuller, &Schneider, 2008).

Another area in which the measurement of speech intelligibility is especially relevant is clinical audiology. The SPIN test has demonstrated its clinical utility in measuring the effects of linguistic cues on speech discrimination in studies by Bilger, Nuetzel, Rabinowitz, and Rzeczkowsky (1984) and Hutcherson, Dirks, and Morgan (1979) for listeners with sensorineural hearing loss or in the study by Del Dot, Hickson, and O'Connell (1992) for

listeners using hearing aids.

There are many other situations in which testing the effects of linguistic knowledge is a relevant issue. For instance, the study by Elliot (1979) evaluated from what age children are able to use contextual or linguistic cues to achieve speech perception in noise, while the study by Mayo, Florentine, and Buus (1997) determined how age of acquisition influences second-language speech perception. In the latter study, differences in the recognition of HP and LP sentences, especially in noise conditions, would indicate the degree to which the nonnative listeners had mastered the ability to profit from the semantic and syntactic information provided by the context.

Another research area of interest is the recognition of speech in noise in elderly listeners. The differences these listeners show for the HP versus LP sentences have been extensively studied (Dubno et al., 2000; Gordon-Salant &Fitzgibbons, 1997; Perry &Wingfield, 1994; Pichora-Fuller, 2008; Pichora-Fuller, Schneider, &Daneman, 1995; Sommers &Danielson, 1999; Wingfield, Tun, &McCoy, 2005). In these listeners, decreases in sensory information due to loss of hearing acuity, especially in adverse listening conditions, can be compensated by information provided by the context (Pichora Fuller, 2008).

Thus, the SPIN test has been applied to a variety of experimental conditions and types of listeners in the English language, and it has proved to be a useful tool in psycholinguistics, psychoacoustics, and audiology.

The objective of the present study was to develop a test to measure the intelligibility of speech in noise for the Spanish language similar to the test developed by Kalikow et al. (1977) for the English language in an experiment conducted to measure the intelligibility of a pool of sentences with different signal-to-noise ratios (SNRs). These sentences were used in a previous study (Cervera &Gonzalez- Alvarez, 2010). In that study, six lists of HP sentences were first generated. These lists had equivalent predictability for the final word. They were also equivalent in length, phonetic content of the sentence, and frequency of the final word. In addition, each HP sentence had its corresponding LP sentence generated by using the same final word but with an LP preceding context, producing six corresponding LP lists.

In the present study, our aim was to assess the intelligibility of these sentences in normal-hearing listeners in three different SNR conditions (0 dB, +5 dB, and +10 dB) using babble noise. We hypothesized that the performance of the listeners on the HP sentences would be higher than the performance on the LP sentences. At the same time, among the three SNR conditions, the +10-dB SNR condition would produce higher scores than the +5-dB SNR condition, and the latter would produce higher scores than the 0-dB SNR condition.

The ultimate objective was to create a set of final lists (hereafter referred to as forms) of equal intelligibility to be used as a test of speech intelligibility in noise for the Spanish language. These forms consist of 50 sentences each (25 HP and 25 LP). The forms must also have equivalent phonetic content, because this characteristic is very important in audiology.

Method

Participants

The participants in the experiment were 474 undergraduate students, 394 from the University of Valencia and 80 from the University of Jaume I. Of these students, 291 were female and 183 were male. Their ages ranged from 21 to 30 years, with a mean age of 23.1 years (SD = 2.6). They received partial credit for a course requirement. None of the participants reported having any hearing or language problems, and they were native speakers of Castilian Spanish.

Stimuli

The stimuli consisted of 150 HP sentences and 150 LP sentences. These sentences were generated in a previous study (Cervera &Gonzalez-Alvarez, 2010). The HP sentences consisted of sentences whose final word was in some way predictable from the preceding context, with values of between 10% and 90% predictability (e.g., "Ata el regalo con una cinta"; "Tie the present with a ribbon"). The 150 sentences were grouped in six lists so that the predictability of all of the six lists was equivalent. These lists were also equivalent in length (all of

them had from seven to ten syllables), phonetic content (with regard to both the whole sentence and only the last word or key word), syllabic structure, word stress, and frequency of the final word.

In addition, each HP sentence had its corresponding LP sentence, generated using the same final word, but with an LP preceding context. An example would be "Ahora voy a decir cinta" ("Now I am going to say ribbon"). Thus, six lists of 25 HP sentences and six lists of 25 LP sentences were created.

These lists were recorded by a native Castilian Spanish female speaker who was accustomed to recording for experimental or clinical purposes. The speaker was required to repeat each sentence 3 times. In addition, the duration of the utterance had to be from 1,800 to 2,000 ms. The clearest production of each sentence recording was selected. The recording took place in a soundproof room, using a Sennheiser HMD 224 microphone set at 15 cm from the lips and directly digitalized in the computer using an Edirol UA-5 sound card, with a sampling frequency of 11.025 kHz, and then the signal was low-pass filtered at 5.5 kHz to prevent aliasing.

The speech materials were edited with Adobe Audition sound editor software. First, each sentence was excised from the recorded list of sentences, creating WAV files of 1,800- 2,000 ms of duration. Visual inspection of the waveform and the spectrogram was used to determine optimal points at which to excise the sentence. Then the intensity of each stimulus was also adjusted so that it would have an equal rootmean square (RMS) across the entire sentence. The final words of the sentences were also equal in intensity.

To create the masking condition, we used babble noise. The babble noise was generated by mixing 12 voices (six males and six females) reading a text. The recording conditions and digitalization of the signal were the same as in the case of the sentence stimuli. The babble noise was mixed with each sentence, creating each of the three SNR conditions, 0-dB, +5-dB, and +10-dB SNR, by manipulating the overall RMS of both the signal and the babble noise. These manipulations were performed using Adobe Audition Pro software.

Procedure

The six lists of HP sentences and the six lists of LP sentences were presented in three different conditions of background noise (0-dB, +5-dB, +10-dB SNR) to a group of 474 listeners. Each individual was presented randomly with one of the following combinations of the HP and LP lists: list 1 (HP) with list 2 (LP), list 2 (HP) with list 3 (LP), list 3 (HP) with list 4 (LP), list 4 (HP) with list 5 (LP), list 5 (HP) with list 6 (LP), and list 6 (HP) with list 1 (LP). By means of these combinations, each participant was presented with both HP and LP sentences, but with no repetition of the final word of the sentence. At the same time, each individual was presented with only one of the three SNR conditions randomly. Thus, 79 individuals completed each of the six list combinations described above. Of each of these 79 participants, 26 of them were presented with the 0-SNR condition, 26 of them were presented with the +5-SNR condition, and 27 of them were presented with the +10-SNR condition.

The listeners participated in the experiment in a soundattenuated laboratory with six cabins. Each cabin contained a Pentium PC with Sennheiser headphones. Before the experiment began, participants were instructed to listen to the sentence and enter the last word of the sentence, using the computer keyboard. The administration of the stimulus and the registration of the responses made by the listener were performed by a Java program developed specifically for this experiment.

Results

Percent correct scores

Figure 1 shows the mean scores (expressed in percentages) obtained by the listeners on the perceptual test for both the HP and the LP sentences in the three conditions of background noise, 0 dB, +5 dB, and +10 dB SNR. For each condition of SNR and for HP and LP sentences, the percentiles of the data obtained by the listeners were calculated as well (see Table 1).

As can be observed in Fig. 1, the HP sentences presented higher perceptual scores than did the LP sentences, as was hypothesized. At the same time, the perceptual scores were higher for the highest SNR condition, +10 dB, followed by the +5-dB condition, and the lower scores correspond to the 0-dB condition, as was

hypothesized.

With the aim of testing whether the differences between the LP and the HP sentences and the differences in the three conditions of SNR were significant, we submitted the data to a two-way ANOVA with percentage of correct scores obtained on the intelligibility test as a dependent measure and type of sentence (HP or LP) and the three SNR conditions (0 db, +5 dB, and +10 dB) as factors or independent variables.

We found significant main effects of type of sentence, $F(1) = 3{,}005.19$, $p < .01$, $\eta 2 = .11$, and SNR condition, $F(2) = 2{,}234.43$, $p < .01$, $\eta 2 = .16$. The interaction was also significant, $F(1, 2) = 77.66$, $p < .01$, $\eta 2 = .007$. A posteriori comparisons of the levels of the SNR factor, by means of the Tukey test, showed significant differences between 0 and +5 dB ($p < .01$), 0 and +10 dB ($p < .01$), and +5 and +10 dB ($p < .01$).

To confirm that the six HP sentence lists did not differ statistically on their intelligibility values, a one-way ANOVA was conducted with correct scores (expressed in percentages) as a dependent variable and list the sentences belonged to (list) as an independent variable with six levels. The results showed no significant effects of list, $F(5) = 2.14$, $p > .05$, $\eta 2 = .069$. Thus, the six HP sentences lists did not differ on their percent correct scores.

The same analysis was carried out for the LP sentences. Responses on the intelligibility test (expressed in percentages of correct scores) were used as a dependent measure. A one-way ANOVA was performed with list the sentences belonged to (list), with six levels, as a factor. We found no significant effects of list, $F(5) = 1.48$, $p > .05$, $\eta 2 = .04$. Thus, the six lists of LP sentences did not differ with regard to their percent correct scores.

Creation of final forms

The second step was to create final forms that would contain both HP and LP sentences. These forms were the result of combining one of the HP sentences lists with one LP sentence list in the following manner: list 1 (HP) with list 2 (LP), called form 1; list 2 (HP) with list 3 (LP), called form 2; list 3 (HP) with list 4 (LP), called form 3; list 4 (HP) with list 5 (LP), called form 4; list 5 (HP) with list 6 (LP), called form 5; and list 6 (HP) with list 1 (LP), called form 6. Thus, the final test instrument contains six forms of 50 sentences each. Within each form, the order of presentation of the HP and LP sentences was randomized. This manner of presentation is the same as that used in the SPIN sentences by Kalikow et al. (1977).

Previously, we confirmed that the HP lists were equivalent in their percent correct scores, as were the LP lists. The next question was to find out whether the final six forms (resulting from the combination of one HP sentence list and one LP sentence list) continued to be equivalent in percent correct scores and phonetic content (the predictability of the final forms did not have to be measured, because this characteristic concerns only the HP sentences and it was tested in the previous study by Cervera &Gonzalez-Alvarez, 2010).

Percent correct scores of the final forms of the test The means and standard deviations of the percent correct scores obtained in the present experiment, for each of the six final forms of sentences across the three SNR conditions, were calculated (see Table 2). In order to have forms that were equivalent in their percent correct scores, a one-way ANOVA was conducted with values of intelligibility (expressed as percentages of correct scores) as a dependent variable and form the sentences belonged to as an independent variable with six levels. The results showed no significant effects of the form to which the sentences belonged, $F(5) = 1.49$, $p > .05$, $\eta 2 = .25$. Thus, it can be concluded that the six final forms of sentences (containing 25 HP and 25 LP sentences) did not differ in their percent correct scores.

Phonetic content of the final forms of the test Another aim of the present study was for the final forms of 50 sentences to have similar equivalent phonetic content. The phonetic counts in each phonetic category were performed separately for the last word of the sentences and for the whole sentence (the preceding context plus the last word). In these counts, only content words (verbs, nouns, and adjectives) were taken into account, while articles, prepositions, and adverbs were not considered. The phonetic counts were calculated by counting the number of occurrences of segments in each phoneme class (occlusives, fricatives, nasals, liquids, and vowels). Phonetic counts were performed by the authors, who had training in this task.

A distribution of frequencies for each phoneme class was obtained for each of the 300 sentences (150 HP sentences and 150 LP sentences), for the whole sentence and for the final word in the sentences alone. Table 3 shows the number of occurrences of each phoneme class for each of the six final forms.

In order to test whether all the forms had equivalent phonetic contents, a chi-square analysis was performed. Two separate tests were performed, for the final words or key words alone and for the whole sentences. Phoneme class (occlusives, fricatives, nasals, liquids, and vowels) and form (six levels) were included as factors in both cases. The chi-square value was not significant for the whole sentences, $\chi 2(20) = 8.13$, $p > .05$, or for the final words of the sentence, $\chi 2(20) = 9.66$, $p > .05$. Thus, the six final forms were equivalent in their phonetic content, whether the whole sentence was considered or only the final words. Finally, the definitive forms containing both HP and LP sentences are presented in the Appendix.

Discussion

Our objective was to generate forms of HP and LP Spanish sentences equivalent in intelligibility (measured as percent correct scores obtained in the perceptual task). These types of sentences have many applications, especially in psycholinguistics and audiology. In psycholinguistics, they could be especially useful in those circumstances in which it would be interesting to assess the sensory or bottom-up processing and the cognitive (effective use of context) or top-down processing capabilities of listeners during language processing. Some examples would be elderly listeners with age-related hearing loss but with intact topdown processing skills, children learning a second language who are not yet completely able to use context to accomplish speech perception, or individuals learning a second language with different levels of language proficiency. In audiology, these sentences can be useful for evaluating hearing aids in different SNR conditions simulating a variety of everyday communicative situations.

As in the case of the SPIN sentences (Kalikow et al., 1977) for the English language, the sentences developed in the present study for the Spanish language are easy to administer. The duration is short (about 10 min per form). The response required by the listeners is simple, because he or she has to respond only with the final word of the sentence. Besides intelligibility (percent correct scores), other characteristics are also controlled, such as phonetic content, sentence length, final word stress, and final word frequency, all of which are quite relevant in audiological evaluation. The utility of the SPIN sentences (Kalikow et al., 1977) has been demonstrated by their utility in audiology and psycholinguistics. For the audiological evaluation of Spanish-speaking listeners or research conducted with Spanish-speaking listeners, it is necessary to have similar speech materials for the Spanish language.

A two-choice sound localization procedure for detecting lateralized tinnitus in animals

Author: Heffner, Henry E

Publication info: Behavior Research Methods (Online) 43.2 (Jun 2011): 577-589.
ProQuest document link

Abstract: Rats were trained in a two-choice procedure to respond in the direction of left and right sounds. Silent trials, on which no sound was presented and for which the animals received no feedback, were interspersed among the sound trials to determine each animal's natural side preference. Following training, the rats were exposed to a loud tone in the ear opposite their side preference. A shift in responding on the silent trials to the side of the exposed ear indicated that the animals were hearing a sound in that ear (i.e., tinnitus). Simulating lateralized tinnitus by presenting a low-level, continuous sound on one side also caused the rats to shift their responding on the silent trials to that side. Sham exposures indicated that halothane/nitrous oxide anesthesia could reinstate tinnitus in animals that had previously tested positive for it. Exposing rats to loud tones of various frequencies indicated that frequencies near the limits of the rat's hearing range were less likely to cause tinnitus than tones in the midrange. Abstract Rats were trained in a two-choice procedure to respond in the direction of left and right sounds. Silent trials, on which no sound was presented and for which the animals received no feedback, were interspersed among the sound trials to determine each animal's natural side preference. Following training, the rats were exposed to a loud tone in the ear opposite their side preference. A shift in responding on the silent trials to the side of the exposed ear indicated that the animals were hearing a sound in that ear (i.e., tinnitus). Simulating lateralized tinnitus by presenting a low-level, continuous sound on one side also caused the rats to shift their responding on the silent trials to that side. Sham exposures indicated that halothane/nitrous oxide anesthesia could reinstate tinnitus in animals that had previously tested positive for it. Exposing rats to loud tones of various frequencies indicated that frequencies near the limits of the rat's hearing range were less likely to cause tinnitus than tones in the midrange.

Keywords Tinnitus * Anesthesia * Noise exposure * Sensorineural threshold shift * Lateralization * Operant

behavior * Rat

Tinnitus refers to the perception of sound in the absence of any corresponding acoustic stimulation; the word itself is from the Latin word for ringing (tinnitus), because the perceived sound is often tonal in nature (see, e.g., Loeb &Smith, 1967; Martines et al., 2010). Although there are a number of causes of tinnitus, two of the more common ones are exposure to loud sound and the ingestion of large doses of ototoxic drugs such as quinine or salicylate, the latter being the active ingredient of aspirin (e.g., Bauer &Brozoski, 2008). In recent years, there has been increased interest in tinnitus, primarily with the goal of finding a treatment for it, although an understanding of how tinnitus arises in the auditory system would also give insight into the neurological basis of the perception of sound. Such studies are best conducted on animals, creating a need for tests that can determine whether an animal has tinnitus.

The usual procedure for assessing animals for tinnitus involves training them on an auditory discrimination task, exposing them to a tinnitus-inducing agent, and testing them to determine whether their performance has changed in some way that suggests they now have tinnitus. The first animal test for tinnitus, developed by Jastreboff, Brennan, Coleman, and Sasaki (1988), involved allowing thirsty animals to drink in the presence of an external sound and training them to stop drinking when the sound is turned off by following sound-off intervals with a foot shock; finding that animals given sodium salicylate or other tinnitusinducing agents are less likely to stop drinking when the external sound is turned off suggests that the animals are hearing sound in the absence of any physical stimulus- that is, they have tinnitus (Jastreboff et al., 1988). Most tests developed since then have also involved training animals to discriminate the presence of external sound from the absence of sound, with the expectation that animals with tinnitus will respond in the absence of external sounds as if a sound were actually present (Bauer, Brozoski, Rojas, Boley, &Wyder, 1999; Guitton et al., 2003; Guitton &Dudai, 2007; Heffner &Harrington, 2002; Kizawa et al., 2010; Lobarinas, Sun, Cushing, &Salvi, 2004; Ruttiger, Ciuffani, Zenner, &Knipper, 2003; Zheng, Hooton, Smith, &Darlington, 2008). Because tinnitus-inducing agents such as loud sounds and ototoxic chemicals usually cause a ignificant hearing loss, all such procedures require controls to demonstrate that a change in an animal's response to sound versus silence is not caused by a reduced ability to hear sound.

Currently, two tinnitus tests differ from the others in the type of discrimination that an animal must make. One is a gap detection test, in which an animal detects a brief silent interval, or gap, in an ongoing sound. If tinnitus similar in frequency to the ongoing sound is present, it is expected to "fill in" the gap, causing a decrement in an animal's gap detection performance (Rybalko &Syka, 2005; Turner et al., 2006). Any accompanying hearing loss can be controlled either by inducing tinnitus in only one ear or by increasing the intensity of the ongoing sound to ensure that it is clearly audible. Although the idea that ongoing tinnitus could interfere with detecting a temporal gap in an external sound of similar spectral characteristics seems intuitive, this effect has yet to be demonstrated in humans, and the view that tinnitus can interact with the perception of external sounds was questioned many years ago (Davis, Morgan, Hawkins, Galambos, &Smith, 1950).

The other nontraditional tinnitus test is the two-choice sound localization test (Heffner &Koay, 2005). In this test, an animal is trained on a sound localization task to make a left or right response to sounds coming from its left or right side, respectively. Silent trials, in which no sound is presented and for which the animal receives no feedback as to how it should respond, are interspersed among the sound trials, and an animal's side preference on those trials is determined. The animal is then exposed to a loud sound in the ear opposite its side preference and tested to see whether it shifts its responding on the silent trials to the side of the exposed ear; doing so would indicate that the animal perceives a sound (tinnitus) that is lateralized to that side, which is conceptually equivalent to a human patient reporting the ear to which their tinnitus is lateralized. In addition to being able to indicate whether an individual animal has lateralized tinnitus, the two-choice procedure would not be expected to be confounded with hearing loss that accompanies exposure to loud sound, an expectation that has been verified by demonstrating that a conductive hearing loss caused by plugging one ear does not cause a shift in

responding on silent trials (Heffner &Koay, 2005). Moreover, because the animals are never given feedback on the silent trials, their responding to their tinnitus may not immediately habituate, making it possible to follow the time course of the tinnitus.

A key assumption of the two-choice test is that exposing an ear to a loud sound will induce tinnitus that is lateralized to that ear-that is, that the tinnitus will neither be lateralized to the unexposed ear nor be bilateral. The three available studies of sound-induced tinnitus in humans suggest that we may make this assumption (Atherley, Hempstock, &Noble, 1968; Davis et al., 1950; Loeb &Smith, 1967). Specifically, each of these studies determined the preexposure absolute thresholds of the subjects, exposed one ear to loud sounds, determined the postexposure absolute thresholds in the exposed ear, and had the subjects match the resulting tinnitus to tones presented to the unexposed ear. None of these studies mentioned the perceived locus of the tinnitus, although it would have been notable had it been lateralized to the unexposed ear. To obtain more information, I contacted Joseph Hawkins, one of the authors and a subject of the Davis et al. study, and he told me that the tinnitus they observed was always lateralized to the exposed ear (J. E. Hawkins, Jr., personal communication, February 25, 2003). Thus, the results of human studies either support or do not conflict with the conclusion that, as long as the exposing sound is presented to only one ear, the resulting tinnitus will be lateralized to that ear.

The purpose of this report is to describe a series of tests that explore the strengths and limitations of the two-choice tinnitus test. These tests include a test for the propensity of sounds of different frequencies to induce tinnitus, a simulated tinnitus test, and a test for the effect of anesthesia on the induction of tinnitus.

Method

Subjects

Thirteen male hooded rats (Rattus norvegicus; Harlan Sprague-Dawley) were used in this study. Six of the rats (Rats A-F) were exposed to loud tones and tested for tinnitus; the other 7 were used in an anesthesia control test. The animals were housed in standard solid-bottom cages with grid covers and pelleted corncob bedding (1/8-in. pellets; Harlan Teklad). The animals were given free access to rodent chow, and their body weights were measured daily. Water was available only during daily training and testing sessions. Pieces of apple were given as needed to maintain a body weight of approximately 85%-90% ad-lib weight. The use of animals in this study was approved by the University of Toledo Animal Care and Use Committee.

Behavioral apparatus

Testing was conducted in a carpeted, double-walled sound chamber (IAC Model 1204; Industrial Acoustics, Bronx, NY; 2.55 ×2.75 ×2.05 m), the walls and ceiling of which were lined with egg-crate foam; the double walls of the sound chamber prevented entry of any sounds audible to the rats. The equipment for behavioral control and stimulus generation was located outside the chamber, and the animals were observed over closed-circuit television. The chamber was carefully checked for the presence of extraneous sounds, including frequencies above the range of human hearing, using a sound level meter (described below); no extraneous sound was found. In addition, the lights within the chamber were low-wattage bulbs so that they did not have to be dimmed, since reducing the voltage of incandescent lights can cause their filaments to emit sound ("sing"). In short, there were no audible background sounds in the chamber.

The animals were tested in a cage (28 cm long ×13 cm wide ×16 cm high) constructed of 1-in. (2.54-cm) wire mesh. The cage was mounted on a table 1 m above the chamber floor. Three water spouts (rat water bottle sipper tubes) served as the response manipulanda. The spouts were mounted in a horizontal row at the front of the cage, 3 cm apart and 6 cm above the cage floor. Each spout, which had an LED mounted on it 3 cm back from the tip, was connected to a separate lick circuit. A 2-cm water bowl was mounted 3 cm above the cage floor below the center spout and was connected to a syringe pump (NE 1000, New Era, Wantagh, NY), located outside the sound chamber, with the water feeding up through a hole in the bottom of the bowl. The water reward was not delivered through the left and right water spouts, because it is difficult to dispense identical amounts, and any imbalance would bias an animal's responding to the spout that delivered more water. Water

spouts were used as response manipulanda because a thirsty animal will learn very quickly to lick a spout for water delivered into a water bowl by initially placing water in both the spout and the water bowl. Electric shock was provided by a Coulbourn AC-resistive small animal shocker connected between the side water spouts and the cage floor.

Acoustical apparatus

Sine waves were generated by a tone generator (Model 2400; Krohn-Hite, Avon,MA) and broadband noise by a noise generator (Model S81-02; Coulbourn, Lehigh Valley, PA). The signals were amplified (Coulbourn Model S82-24) and sent to one of two piezoelectric tweeters (Model KSN 1005A; Motorola, Chicago, IL) that were located just outside the cage, 90° to the left and right of an animal's head when it was licking the center spout. The training stimulus was broadband noise (60 dB sound pressure level [SPL], 43 dB above the average threshold of 3 of the rats used in this study) combined with a tone; the noise was used because it is easily localized, and tones were used because it was expected that tinnitus induced by exposure to a loud tone would be tonal (Davis et al., 1950). To accustom the rats to respond to a range of tonal stimuli, the frequency of the tone was changed each day on a random schedule among six different frequencies (10, 12.5, 16, 20, 25, and 32 kHz presented 43 - 58 dB above the average rat threshold; Heffner, Heffner, Contos, &Ott, 1994). Noise alone was presented after an animal had been exposed to a loud sound to induce tinnitus. Because the tone exposures often caused a temporary threshold shift, the intensity of the broadband noise was increased by 5 - 15 dB, as needed, to maintain good performance on the sound trials.

A simulated tinnitus test was conducted by placing a third loudspeaker at 90° to one side and presenting a 16-kHz, 1/3-octave band of noise filtered with a Krohn-Hite 3202 bandpass filter (24 dB/octave roll-off) 25 dB above the rat's absolute threshold. Noise was used because it is more easily localized by rats than tones (Wesolek, Koay, Heffner, &Heffner, 2010); it was filtered to make it distinguishable from the broadband noise used in the sound trials.

The SPL was measured using a Brüel &Kjæ r (B&K) 1/4-in (0.64-cm) microphone (Model 4135; B&K, Naerum, Denmark) and measuring amplifier (B&K Model 2608). The measuring equipment was calibrated with a pistonphone (B&K Model 4230).

Behavioral procedure

A rat was first trained to lick the center spout, an action that turned off the LED on that spout and that was rewarded by delivering water into the water bowl located below it. Next, the rat was trained to lick the center spout and then a side spout to get the water reward. Initially, the correct side response was indicated by presenting the noise/tone from the loudspeaker on that side and by illuminating the LED over the correct spout. Once the rat's performance reached 80% correct or better, both side LEDs came on to signal that a side response should now be made, without indicating the correct side. Thus, licking the center spout turned off the center LED, illuminated both side LEDs, and turned on the noise + tone signal from either the left or the right loudspeaker. Licking a side spout turned off the side LEDs, and correct responses were rewarded by dispensing 0.06 ml of water into the water bowl. Incorrect responses, on the other hand, were punished with an electric shock delivered between the spout and the cage floor; the shock levels were 1.25 mA or less and were sufficiently low that the animals never developed a fear of the spouts and continued to respond after receiving a shock. The center LED was then turned back on and the animal permitted to initiate another trial. The frequency of the tone embedded in the noise was changed from session to session to accustom the animals to respond to different tones, on the expectation that their tinnitus would be tonal.

In the final stage of training, "silent" trials were randomly inserted, on which licking the center spout initiated a trial (signaled by the side LEDs), but no sound was presented. The rat was required to make a side response, but was neither rewarded with water nor punished with a shock; thus, it received no feedback on the silent trials. Approximately 24% of the trials in a session were silent trials. At this time, a 50% feedback schedule was also instituted for the sound trials, according to which, randomly, half of the sound trials were also not followed

bywater reward or shock, regardless of a rat's side response. Instead, the side LEDs were turned off and the center LED turned back on, so that the rat could start another trial. The purpose of the 50% feedback schedule was to accustomthe rats to a partial-reward schedule so they would be less likely to learn that silent trials were never rewarded or punished. The use of the partial feedback did not affect performance on the sound trials, and responses on silent trials were generally stable.

The left-right trial sequence was determined by a quasirandom schedule (Gellermann, 1933). A correction procedure was used for those sound trials on which a rat made an error and received a shock (i.e., errors on feedback trials), in that the correct side did not change on the next trial; the results of these correction trials were not included in an animal's score. The animals were trained until they consistently performed at a level of 90% correct or better on the sound trials. The final test consisted of exposing one ear to a loud tone and then testing the rat to determine whether its responding on silent trials shifted to the side of the exposed ear. Each session lasted until the rat had received sufficient water to maintain a consistent body weight, approximately 85% - 90% of ad-lib weight, yet still be sufficiently motivated to work the next day; increasing the amount of reward resulted in an animal that would not work for water the following day. A typical session lasted about 20-30 min, during which time a rat received about 75 silent trials interspersed among over 200 sound trials.

The performance of a rat on the silent trials was scored as the percentage of silent trials on which it responded to the left side. Thus, for example, a score of 80% indicated that a rat had a left preference on the silent trials, whereas a score of 30% indicated that it had a right preference. We have found that approximately half of the animals prefer the left and the other half the right side, with the degree of the preference varying between individuals but remaining stable. To ensure that the animals' had adapted to the procedure and that their performance was stable, they were trained for 70 sessions before being exposed to a loud tone to induce tinnitus.

Following exposure to a loud tone, a rat's score on the silent trials for a session was compared with its scores on silent trials for the five sessions preceding exposure. This was done by calculating a z score for each session, using the mean and standard deviation of an animal's five preceding preexposure sessions. A positive score for tinnitus was defined as a z score equal to or greater than the .01 one-tailed criterion for the preexposure scores (i.e., M + SD * 2.33).

Inducing tinnitus

To induce tinnitus, a rat was exposed to a loud sound in the ear opposite the side that it preferred on silent trials. The rat was lightly anesthetized (2% halothane with a 1:1 mixture of nitrous oxide and oxygen), and a foam earplug was placed in its nonexposed ear, with the pinna taped over the meatus to protect it from the sound. The rat was then placed on its side with the nonexposed ear on a pad. The exposing sound was produced by a digital signal generator (Model 3525, Zonic), amplified (Model MPA, 100-W/channel, Radio Shack), and sent to a piezoelectric loudspeaker (Motorola KSN 1005A) or a midrange driver (Electro- Voice 1823M). A plastic funnel with a 4-mm inner diameter tip was attached to the loudspeaker with thermoplastic adhesive, and the tip of the funnel was placed 2 mm from the concha. The sound was measured with the 1/4-in. microphone placed 2 mm from the tip of the funnel. The animal was closely observed for the duration of the exposure to ensure that the funnel tip remained in place. The anesthesia was turned off a few minutes before the exposure ended, so that the animal was becoming conscious by the time the exposure was complete. This allowed behavioral testing to begin within 10 min following the exposure.

The exposing tones consisted of nine different frequencies that were presented at a level of 110 dB SPL for 10 min (the level of each tone above the average rat threshold is shown in Table 1). Each animal was exposed to each of the tones, so that the degree to which the tones produced tinnitus could be compared within and between animals. Because the absolute thresholds of humans exposed to similar levels of sound return to normal within 24 - 48 h (Davis et al., 1950), allowing at least 8 days between exposures seemed sufficient to minimize interactions between exposures.

Results

The following sections describe the results of the anesthesia control tests, tone exposures, and simulated tinnitus tests. The order in which the rats were exposed to the different tones and whether or not they tested positive for tinnitus are shown in Table 2.

Anesthesia control test conducted on unexposed rats

Figure 1 illustrates the performance of 7 rats on the silent trials before and after being given a sham exposure that was identical in all respects to the real exposures, with the exception that the exposing tone was not turned on. Three points can be drawn from these results. First, anesthetizing previously unexposed animals does not affect their scores on silent trials, even though testing was begun within 10 min after the anesthesia was discontinued. Second, the scores on the silent trials are relatively stable, generally remaining within one standard deviation of the baseline mean over the 23-day test period. Finally, it may be noted that these results do not entirely rule out the possibility that the anesthesia might cause tinnitus, because the test used here was designed to detect monaural tinnitus and might not detect tinnitus that is not lateralized to one side.

Effect of exposure to loud tones

Figures 2 and 3 illustrate the performance of 6 rats on the silent trials before and after exposure to a loud tone (110 dB SPL for 10 min). As can be seen, scores that were positive for tinnitus generally occurred on the day of the exposure (behavioral testing was begun within 10 min following the exposure). In addition, some animals did test positive on subsequent days, indicating that they still had tinnitus.

Exposure to frequencies from 2 to 24 kHz was more likely to result in a positive score than were exposures to higher and lower frequencies (Fig. 4). There does not appear to be any simple relationship between the sensation level (SL) of the exposing tone (its level above threshold) and the degree to which a tone causes tinnitus, since 32 kHz presented at 111 dB SL was less likely to induce tinnitus than 2 kHz presented at 88 dB SL (cf. Table 1 and Fig. 4). Instead, it appears that exposure to frequencies toward the high- and low-frequency ends of an animal's hearing range may be less likely to cause tinnitus than those in the midrange.

Effect of anesthesia on previously exposed animals

The 6 rats used in the tone exposure tests were given three sham exposures (anesthetized, but not exposed to sound). The first sham exposure was given after they had been exposed to seven tones, with the last two sham exposures given after they had been exposed twice more to loud tones (55 and 61 days after the first sham exposure, respectively). As can be seen in Table 2 and Fig. 5, 2 of the rats never tested positive (B and C), 1 tested positive once (F), and 3 tested positive twice (A, D, and E); in short, the sham trials yielded a positive score for tinnitus about one out of three times. Because the unexposed rats never tested positive for lateralized tinnitus (Fig. 1), this result suggests that the halothane/nitrous oxide anesthesia may have reinstated tinnitus in animals that had previously had it. Thus, it is possible that, after the first exposure, some of the positive scores in Figs. 2 and 3 were due to the anesthesia.

Simulated tinnitus

The effect ofmonaural tinnituswas simulated by continuously presenting a 16-kHz band of noise at 25 dB above the rat threshold. The sound was presented from a loudspeaker located on the side of the animal opposite the side it normally preferred on the silent trials. The results showed that, although all 6 of the animals shifted their responding on the silent trials on the first day, 2 of them(Rats D and F) failed to respond to it on one or more of the subsequent sessions (Fig. 6). This failure to shift on some sessions may reflect habituation to the simulated tinnitus.

Hearing loss

As noted in the Method section, the level and duration of the exposing tones (110 dB for 10 min) was chosen because the absolute thresholds of humans exposed to such tones return to normal levels within 24 - 48 h (Davis et al., 1950). However, due to time constraints, it was not possible to determine the rats' threshold shifts using behavioral tests, and physiological measures of sensorineural hearing loss, such as the auditory

brainstem response, are not sufficiently reliable to be useful (Heffner, Koay, &Heffner, 2008). However, because a sudden unilateral hearing loss will disrupt sound localization performance, an indication of the resulting hearing loss can be obtained from an animal's performance on the sound trials.

Table 3 shows the number of days following exposure before an animal's score on the sound trials returned to a level within the range of the five sessions preceding the exposure. As this table shows, the most common occurrence (38 out of 54 instances) was for an animal's score on the sound trials to drop on the day of the exposure and to return to preexposure levels on the following day (indicated by a 1 in Table 3). In 9 instances, the exposure did not noticeably affect performance (indicated by 0), whereas in the remaining 7 instances, recovery to preexposure levels did not occur until 2 days after exposure (indicated by a 2). In this respect, the recovery time for the rats' thresholds is similar to that of humans exposed to the same SPLs (Davis et al., 1950). Although these results do not prove that the animals had no residual hearing loss, they do demonstrate that any such loss had no noticeable effect on their sound localization performance. With regard to the silent trials, background sound that could have biased the animals on the silent trials to the side of the unexposed ear was eliminated by the double-walled sound chamber that prevented outside sounds from entering the chamber and by using equipment within the chamber did not produce any detectable sound.

Discussion

The two-choice sound localization test provides a conceptually straightforward test of lateralized tinnitus in animals. One of the strengths of this test is that each animal serves as its own control, making it possible to assess tinnitus in individual animals. However, no test is without its limitations, and the following discussion explores the accuracy and reliability of this test. (For brief descriptions of other animal tinnitus tests, see the reviews by Bauer&Brozoski, 2008, and Turner, 2007.)

Accuracy of the two-choice procedure in detecting tinnitus

The first requirement of any diagnostic test is accuracy- that is, it should correctly distinguish individuals that have a particular disorder from those that do not. The anesthesia control test addressed the question of whether an animal that has not been exposed to a loud sound will test positive for tinnitus. As shown in Fig. 1, none of the 7 rats tested positive on the day of the sham exposure, nor did their side preference on the silent trials vary significantly during the following 2 weeks. Thus, the possibility of a false positive result for this test appears quite low.

The probability that an animal with tinnitus would test positive on the two-choice test was addressed in the simulated tinnitus test, in which a low-level (25 dB SL), 16-kHz, 1/3-octave band noise was continuously presented on one side. As shown in Fig. 6, all 7 of the rats tested positive on the first day, indicating that the test is 100% effective in detecting the onset of simulated tinnitus, at least tinnitus that has a salience to an animal that is equal to or greater than the 25-dB SL noise used here. However, 2 of the rats (D and F) did show some adaptation to the 16-kHz noise, and failed to test positive on some subsequent days, indicating that after the first day, the detection rate of this test drops to 84%. However, it may be possible to increase the success rate by training animals prior to exposure to respond to simulated tinnitus for longer periods of time prior to exposure and by selecting animals that respond reliably to simulated tinnitus over long periods of time.

Finally, for this procedure to work as described, the tinnitus must be lateralized to one side or the other. As a result, it may not work well in cases of bilateral tinnitus, such as that induced by salicylate or other chemicals. However, since it is well established that tinnitus caused by exposing one ear to a loud sound is always lateralized to the exposed ear (Atherley et al., 1968; Davis et al., 1950; Loeb &Smith, 1967), this procedure should work well for tinnitus caused by overstimulating or otherwise damaging one ear.

Effect of anesthesia

The effect of anesthesia proved interesting, because it caused some of the previously exposed rats to test positive for lateralized tinnitus (Fig. 5), whereas none of the unexposed animals tested positive (Fig. 1). As previously noted, we cannot rule out the possibility that some of the unexposed animals might have developed

tinnitus that did not affect their responding, because it was not lateralized. Nevertheless, these results suggest that the anesthesia was not the primary cause of the tinnitus, but rather was reinstating it.

Although the anesthesia control tests suggest that up to a third of the positive scores could be due to the anesthesia, there are two reasons why the actual number is probably lower. First, the effect of the anesthesia would not be expected to occur for the initial tone exposures, and thus the first positive score for each animal is unlikely to have been the result of the anesthesia. Second, there would be instances in which both the tone and the anesthesia were sufficient to produce tinnitus.

In humans, general anesthesia is not considered to produce transient tinnitus (Schaaf, Kampe, &Hesse, 2004), possibly because, as the results here suggest, most individuals will not experience it, and it will be gone within 24 h in those that do. With regard to animal research, this finding has several implications. First, to avoid the possibility of anesthesia reinstating tinnitus, subsequent exposures to loud sound should be made with the animal restrained but not anesthetized. Second, the fact that anesthesia can reinstate tinnitus is itself of interest. For example, do anesthetics vary in their ability to reinstate tinnitus, and if so, what are the mechanisms underlying the differences? Finally, other events might be able to reinstate tinnitus, such as a brief exposure to a loud sound that, by itself, would not be expected to cause tinnitus; indeed, to avoid such a possibility, the metal lid of the animal box in which the rats in this study were weighed and transported was padded, to avoid producing the loud sounds that can occur when the lid is placed on or removed from the box.

Effect of frequency of the exposing tone

Although the order in which the rats were exposed to the different tones was not sufficiently randomized to permit a detailed comparison, it does appear that some tones were less likely to cause tinnitus than others. Whereas at least 4 of the 6 rats tested positive for tinnitus when exposed to frequencies from 2 to 24 kHz, exposure to 1 and 45 kHz caused only 2 of the 6 animals to test positive, and exposure to 32 kHz resulted in only one positive score (see Fig. 4 and Table 2). As previously noted, this result does not seem related to SL; for example, 32 kHz, which was presented at 111 dB SL, was less likely to induce tinnitus than 2 kHz, which was presented at 88 dB SL. Nor can it be easily attributed to the order in which the rats were exposed, in that some positive scores might result from the anesthesia reinstating tinnitus. This is because the 45-kHz exposures came relatively late in the series, and the 1-kHz exposure was the last one given; although the 32-kHz exposures were given relatively early in the sequence, the 2-kHz exposures were made, on average, even earlier, and they resulted in four positive scores.

Given that the highest and lowest frequencies audible to the Norway rat at a level of 60 dB SPL are 0.530 and 68 kHz (Heffner et al., 1994), it appears that frequencies within an octave of an animal's 60-dB low- and high-frequency hearing limits are less likely to produce tinnitus than frequencies in the midrange. Whether one or another midrange frequency is more likely to produce tinnitus is not yet clear.

Duration of tinnitus

For the 36 occasions on which a rat tested positive for tinnitus immediately after exposure, the animal tested positive on a subsequent day 17 times. Of these 17 instances, 11 were cases in which the rat tested positive, then negative, and then positive again. A good example of this pattern of responding is the 45-kHz exposure of Rat A (Fig. 3). Because Rats D and F showed a similar pattern of responding in the simulated tinnitus test (Fig. 6), it is possible that the tinnitus was not the element that varied, but the response of the animals to the tinnitus. One way to improve the ability of the two-choice test to follow tinnitus would be to use the simulated tinnitus test to select animals that do not habituate to the external stimulus. Another would be to train animals by occasionally rewarding them for going to the side of the simulated tinnitus prior to inducing tinnitus.

Salience of the resulting tinnitus

As can be seen in Figs. 2, 3 and 4, the degree of an animal's shift to the side of the exposed ear varied greatly, and it may well indicate the salience of tinnitus. For example, Rat A's tinnitus following its exposure to 45 kHz may have been louder than that following its exposure at 32 kHz. This relationship could be explored and

quantified by giving animals simulated tinnitus tests using a range of frequencies and intensities.

Tinnitus and stress

Because stress has been implicated as an aggravating factor, or even a cause, of tinnitus (see, e.g., Knipper, Zimmermann, &Müller, 2010), the question arises as to whether the procedures used here may have increased an animal's level of stress. One potential source of stress is water deprivation, which increases the levels of hormones and proteins (c-Fos) that are associated with stress (Arnhold, Wotus, &Engeland, 2007; Jørgensen, Knigge, Kjæ r, &Warberg, 2002). However, most studies have only looked at the initial effects of restricting an animal's water intake (e.g., 1 or 6 days as in the previously cited studies), and a longer-term study found that hormonal levels in rats on water restriction had returned to normal by 8 weeks (Sakellaris &Vernikos-Danellis, 1974). Given that the rats in the present study were on water restriction for 14 weeks before being exposed to loud sound, they had time to become adapted to the procedure.

A second potential source of stress is the shock that the animals received when they made an error on the sound trials (the use of shock was necessitated by our observation that rats do not perform well on a two-choice sound localization task if errors are not punished). Although the shock was individually adjusted for each rat to the lowest level that would maintain good performance, it would have to cause some stress to be effective. As with water restriction, the animals had 14 weeks to become adapted to the procedure.

Finally, it can be argued that the light anesthesia used to immobilize the rats during the monaural exposure to loud sound was stressful. Indeed, it is possible that the occasional reinstatement of tinnitus in some rats following anesthesia was due to the stress of being anesthetized rather than being a direct effect of the anesthesia itself. As previously noted, animals could be exposed to loud sound without anesthesia by restraining them, although they would have to be acclimated to this, because restraint itself can cause stress (e.g., Jørgensen et al., 2002)-and they would then hear the loud sound, which would also be stressful.

In short, as with an animal's life in the wild, it is virtually impossible to eliminate all potential stressors, especially in tasks that require vigilance and effort, although stress can be minimized. For example, if water restriction proves to be more stressful than food restriction, a food reward can easily be substituted for the water reward. However, a better understanding of the role of stress on tinnitus awaits studies of its effect in humans, because current knowledge is based primarily on clinical observations as opposed to empirical studies (e.g., Hébert &Lupien, 2007).

Author note I thank K. Marchetto for conducting the behavior tests and R. Heffner and G. Koay for their comments on an earlier draft of the manuscript. Also greatly appreciated were the comments of an informed and diligent reviewer. Supported by NIH Grant DC03258.

ProQuest document link

Abstract: Introduction: Cisplatin (CDDP) is an effective and widely used chemotherapeutic agent for pediatric tumors, and ototoxicity is one of the dose-limiting side effects. Objective: It was the aim of our study to investigate the effect of acetyl L-carnitine (ALCAR) on experimental CDDP ototoxicity by audiologic tests, histomorphologic, immunohistochemical and ultrastructural examinations and to investigate the apoptotic pathways. Materials and Methods: Wistar albino rats (n = 28) were studied. Baseline audiological tests were performed in 4 groups: group 1, control; group 2, ALCAR; group 3, CDDP; group 4, CDDP + ALCAR-administered rats. Control audiological tests were performed on the 3rd day, and then the rats were sacrificed. Ear and brain specimens were examined by transmission electron microscopy, and caspase 3, 8 and 9 activities were investigated. Results: The CDDP-administered rats showed significant auditory brainstem response threshold shifts using all stimuli (clicks, 6-kHz and 8-kHz tone burst) compared with the control groups. The CDDP + ALCAR-administered rats showed significant auditory brainstem response threshold shifts by only click stimuli compared with the control groups. In the brain, spiral ganglion and organ of Corti, ultrastructural damage was prominent in group 3; the number of TUNEL (terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling)-positive cells and caspase 3, 8 and 9 immunostaining cells was significantly high in group 3. Conclusion: ALCAR improves CDDP-induced auditory impairment, and also antioxidative and antiapoptotic properties of ALCAR on CDDP ototoxicity were supported by the findings. [PUBLICATION ABSTRACT]

AbstractIntroduction: Cisplatin (CDDP) is an effective and widely used chemotherapeutic agent for pediatric tumors, and ototoxicity is one of the dose-limiting side effects. Objective: It was the aim of our study to investigate the effect of acetyl
L -carnitine (ALCAR) on experimental CDDP ototoxicity by audiologic tests, histomorphologic, immunohistochemical and ultrastructural examinations and to investigate the apoptotic pathways. Materials and Methods: Wistar albino rats (n = 28) were studied. Baseline audiological tests were performed in 4 groups: group 1, control; group 2, ALCAR; group 3, CDDP; group 4, CDDP + ALCAR-administered rats. Control audiological tests were performed on the 3rd day, and then the rats were sacrificed. Ear and brain specimens were examined by transmission electron microscopy, and caspase 3, 8 and 9 activities were investigated. Results: The CDDP-administered rats showed significant auditory brainstem response threshold shifts using all stimuli (clicks, 6-kHz

Introduction

Cisplatin (CDDP) is an effective anticancer agent for the treatment of children with a wide spectrum of pediatric solid tumors [1]. Platinum-based chemotherapeutics differ in effectiveness and safety. Ototoxicity, neurotoxicity and nephrotoxicity are major dose-limiting side effects of CDDP. CDDP-induced ototoxicity is character-

ized by bilateral, usually permanent, high-frequency sensorineural hearing loss that can progress to the lower frequencies [26]. There is an individual susceptibility to CDDP ototoxicity. It has been suggested that depletion of cochlear antioxidant enzyme activities and reciprocal increase in reactive oxygen species and lipid peroxidation may lead to apoptosis within cochlear cells [79]. Cytotoxicity by the platinum derivatives was dependent on cellular accumulation of platinum and suggested to be mediated by apoptosis and necrosis [10] . Various methods have been studied in order to prevent the side effects of CDDP. Antioxidants, particularly thiol-based antioxidants, have been used to prevent CDDP ototoxicity [8, 9]. Recently, it was shown that geranylgeranylacetone had a protective effect on CDDP ototoxicity due to the induction of heat shock protein 70 and the inhibition of inflammation [11] . However, all of these agents may interfere with the antitumor effects of CDDP. Thus, new treatment strategies which will not interfere with the antitumoral effects of CDDP to limit CDDP ototoxicity are necessary.

L -Carnitine is a natural micronutrient, antioxidant and free radical scavenger. It is a cofactor required for transformation of free long-chain fatty acids into acetyl carnitines, as well as for their transport into the mitochondrial matrix, where they undergo [H9252]-oxidation
[12, 13]. Acetyl L-carnitine (ALCAR) is a short-chain ester derivative of L-carnitine, synthesized in the human brain, liver and kidney. It is a well-known neuroprotective agent and is also protective against CDDP-induced neurotoxicity [1417]. Also, it has antiapoptotic effects on various cell types [1821].

In this study, we aimed to investigate the protective role of ALCAR on CDDP-induced ototoxicity by audiologic tests, histomorphologic, immunohistochemical (IHC) and ultrastructural examinations (transmission electron microscopy), and also to investigate the apoptotic pathways.

Materials and Methods

AnimalsAdult female Wistar albino rats, weighing 200300 g, were obtained from the Laboratory Animal Science Department, Dokuz Eylul University, Izmir, Turkey. The animals were housed in controlled environmental conditions (20 8 2C, 55% relative humidity and 12-hour light/dark cycle) and had free access to pulverized standard rat pellet food and tap water. The protocol of this study has been approved by the Local Ethical Committee of Dokuz Eylul University Animal Care and Use. Animals with signs of external ear disorders, or middle ear disorders before drug injection, were all excluded from the study.

Materials

CDDP vials (50 mg/100 ml; Cisplatin-Ebewe [L50128] , Liba, Turkey) were used. ALCAR (Sigma, Germany) was supplied and freshly dissolved in normal saline with a concentration of 10 mg/ml prior to injection. Disodium ethylenediaminetetraacetic acid (EDTA) was obtained from Merck (Germany). HEPES [4-(2-hydroxyethyl)-1-piperazineethanesulfonic acid], DTNB [5,5 [H11541][notdef]dithio-bis(2-nitrobenzoic acid)] and L-carnitine hydrochloride were purchased from Sigma-Aldrich (Germany). Acetyl coenzyme A and carnitine acetyltransferase (5 mg/ml) were supplied by Roche Diagnostics (Barcelona, Spain).

Experimental Design

Twenty-eight adult female Wistar albino rats were divided into 4 groups, as follows: group 1 (control, n = 7): saline-supplemented control rats; group 2 (ALCAR, n = 7): ALCAR-administered rats; group 3 (CDDP, n = 7): CDDP-administered rats; group 4 (ALCAR + CDDP, n = 7): CDDP-administered rats following ALCAR pretreatment.

All rats were subjected to anesthesia with ketamine hydro-chloride of 60 mg/kg/dose and xylazine hydrochloride of 5 mg/ kg/dose during audiologic testing and also during intraperitoneal infusion of fluids/drugs. Although there was free access to water, all animals were also hydrated with a daily injection of saline of 5 ml/kg for 3 days.

After hydration with saline (30 min apart), rats in groups 2 and 4 were subcutaneously injected with ALCAR (200 mg/kg), while rats in groups 1 and 3 were subcutaneously injected with the same doses of normal saline for 3 days.

Following subcutaneous injections (30 min apart), rats in groups 3 and 4 were given 1-hour intraperitoneal infusion of CDDP (16 mg/kg), and rats in groups 1 and 2 were given 1-hour intraperitoneal infusion of the same doses of normal saline only for the first day.

Auditory AssessmentAuditory brainstem response (ABR) testing was performed before administration and 3 days (72 h) after injections (fig.1). Only animals with normal otoscopy were anesthetized as described previously. ABRs were recorded using ICS Medical Charter equipment in a silent room. The insert earphone delivered sound through an extended polyethylene tube direct into the rats external auditory canal. Neonatal probe tip was used for sealing the external auditory canal. Subdermal electrodes were placed over the vertex (active), right and left retroauricular regions (negative) and on the dorsum (ground). The stimuli used were alternating clicks (with a duration of 0.1 ms) at a rate of 21.1/s, and tone bursts of 6 and 8 kHz (duration of 1 ms, 2 ms rise/fall times) at a rate of 31.1/s. Electroencephalographic activity was pre-amplified for a voltage gain of 100,000 and band-pass, analog-filtered from 100 to 3,000 Hz for click stimuli, and from 30 to 1,500 Hz for tone bursts. The number of averaged responses was 1,024, and always, each average response was replicated. Each series of stimuli started at the suprathreshold level, and tests were run from high to low levels.

Sacrifice and Tissue Sampling

The rats were sacrificed after auditory assessments were done on the 3rd day of CDDP/saline administration. All rats were subjected to anesthesia with ketamine hydrochloride and xylazine

a b

Fig. 1.

a Auditory evoked brainstem response by click stimuli before CDDP injection. b Auditory evoked brainstem response by 6-kHz tone burst stimuli after CDDP injection (wave V threshold is 60 dB nHL).

hydrochloride, and then sacrificed by creating hypovolemia through venosection from the abdominal vein. The tissue samples including the brain and both inner ears (hair cells and spiral ganglia) were examined by ultrastructural, IHC and morphometric methods. The Olympus BH-2 (Tokyo, Japan) and JVC TK-890E (Japan) high-resolution video cameras were used for light microscopic and morphometric examinations.

IHC Procedure

IHC examinations of hair cells, spiral ganglia and brain tissues were done. Caspase 3, 8 and 9 activities were examined by IHC methods. The avidin-biotin peroxidase system was used for IHC examination, and caspase 3, 8 and 9 activities were studied. With the IHC method, 5- [H9262]m-thick sections were cut and incubated at 60 C overnight and then dewaxed in xylene for 30 min. After dehydrating in decreasing concentrations of ethanol, sections were washed in distilled water for 10 min. Then they were treated with 10 m

M citrate buffer (Cat No. AP-9003-125, Labvision) at 95 C for 5 min to unmask antigens by heat treatment. Afterwards, slides were cooled in buffer for 20 min and washed in deionized water 3 times for 2 min. Sections were delineated using a Dako pen (Dako, Glostrup, Denmark) and incubated in 3% H 2O2 for 15 min to inhibit endogenous peroxidase activity. After being incubated with normal serum blocking solution for 30 min, sections were incubated in a humid chamber overnight at 4 C with antibodies to caspase 3 (1/100, rabbit polyclonal; sc-7148, Santa Cruz Biotechnology), caspase 8 (1/100, rabbit polyclonal; sc-6134, Santa Cruz Biotechnology) and caspase 9 (1/100, goat polyclonal; sc-7885, Santa Cruz Biotechnology). Then they were washed 3 times for 5 min with phosphate-buffered saline (PBS), followed by incubation with biotinylated IgG and then with streptavidin-peroxidase conjugate (Zymed 85-9042, Lot No. 20570999, Calif., USA). Sections were washed with

PBS and incubated with diaminobenzi-dine (DAB) substrate containing DAB (Zymed 00-2020, Lot No. 21074104, Calif., USA) for 5 min to detect immunoreactivity, and
then counterstained by Mayers hematoxylin. PBS washing was repeated 3 times, and sections were covered with mounting medium and were analyzed on a bright-field light microscope (Model BX40, Olympus, Tokyo, Japan). Control samples were processed in an identical manner, but lacking the primary antibody step [22].

TUNEL Procedure

The degree of apoptosis was assessed with the TUNEL (terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling) procedure using a commercially available in situ apoptosis detection kit. The procedure was performed using the In Situ Cell Death Detection Kit POD (Cat No. 1684817, Roche, Mannheim, Germany), according to the manufacturers protocol. Briefly, serial 5- [H9262]m-thick paraffin-embedded sections were deparafinized, rehydrated in graded alcohol, washed in distilled water followed by PBS and deproteinized by proteinase K (20 [H9262]g/ml) for 30 min at 37 C. Then the sections were rinsed and incubated in the TUNEL reaction mixture. Labeling was visualized using converter POD with 0.02% DAB and counterstained with 0.5% methyl green applied to the slides and washed with 0.5% methyl green, dehydrated and mounted. The percentage of TUNEL-positive cells was determined by counting the positive cells on 5 random fields from 5 serial sections of 5 rats in each group. The apoptotic index was defined as the number of apoptotic TUNEL-positive cells of tubules. The images were analyzed using a computer-assisted image analyzer system consisting of a microscope (Olympus BH-2) [22].

Ultrastructural ProcedureFor hair cells and spiral ganglia examinations, the temporal bones of the animals were removed, enumerated, fixed in 2.5% glutaraldehyde, then decalcified using 0.1 mol/l EDTA, sucrose and 2.5% glutaraldehyde with phosphate saline. After decalcification, inner ears were removed and embedded into resin. Then

they were postfixed in 1% osmium tetroxide with phosphate buffer for 1 h. The brain tissue samples were taken by routine ultrastructural procedure. Thereafter, all tissue samples were dehydrated in serial alcohol and then embedded in araldite. The semi-thin sections were stained with toluidine blue and examined with a photomicroscope (BH2 Olympus). After the selection of appropriate specimens, thin sections were obtained and stained with uranyl acetate and lead citrate. They were examined with an electron microscope (Carl Zeiss Libra 120) [23].

Statistical Analysis

IHC examination of hair cells and spiral ganglia was technically difficult, and the statistical analysis of the IHC examination results of these tissue samples was done from 5 rats in all groups. Five different sections with 10-[H9262]m intervals were taken from all samples, and cells were counted from 5 different fields of all sections. The brain tissue samples of all 7 rats in 4 groups were examined. The same number of serial tissue sections was examined by the same number of examination fields, and statistical analysis was done. Morphometric analysis was performed by the Leica DCM 4000 visual analysis system and by the Q WIN3 program. All statistical analyses were done using the SPSS 11.0 software program. All results are expressed as means8 SEM. The mean values of groups were compared by the Kruskal-Wallis analysis, and p ^ 0.05 was considered statistically significant.

Results

Auditory AssessmentCDDP-treated rats showed significantly higher ABR threshold levels by all stimuli (clicks, 6-kHz and 8-kHz tone burst) compared to the control groups (p ! 0.01). CDDP + ALCAR-treated rats showed significant ABR threshold shifts by click stimuli when compared to the control groups (p ! 0.01). CDDP-treated rats had significantly higher click ABR threshold levels compared with the CDDP + ALCAR group (p ! 0.01).

Mean ABR threshold shifts in the 4 rat groups are presented in figure 2 .

TUNEL ResultsThe number of TUNEL-positive hair cells was statistically significantly high in group 3 when compared to groups 1, 2 and 4 (0.096 8 0.02, 0.016 8 0.009, 0.016 80.009 and 0.024 8 0.009, respectively; p ! 0.05). There was no statistically significant difference between groups 1, 2 and 4 (p 1 0.05). The number of TUNEL-positive spiral ganglia cells was statistically significantly higher in group 3 when compared to groups 1, 2 and 4 (0.136 80.02, 0.048 8 0.014, 0.040 8 0.012 and 0.08 8 0.012, respectively; p ! 0.05). There was no statistically significant difference between group 3 and group 4 (p = 0.151). In
brain tissue, the number of TUNEL-positive neurons was significantly higher in group 3 when compared to groups 1, 2 and 4 (1.034 8 0.044, 0.097 8 0.025, 0.074 8 0.010 and 0.382 8 0.114, respectively; p ! 0.05). There was no statistically significant difference between group 1 and group 2 (p 1 0.05).

The number of TUNEL-positive cells in the brain, spiral ganglion and organ of Corti was statistically significantly higher in group 3 when compared to groups 1, 2 and 4. Although the number of TUNEL-positive cells was high in group 4 when compared to groups 1 and 2, there was no statistically significant difference.

IHC Results

IHC Examination of Caspase 3. In spiral ganglia and brain tissues, the number of caspase-3-immunopositive cells was statistically significantly higher in group 3 when compared to groups 1, 2 and 4 (p ! 0.05). There was no statistically significant difference between groups 1, 2 and 4 (p 1 0.05).

IHC Examination of Caspase 8. In spiral ganglia, the number of caspase-8-immunopositive cells was significantly higher in group 3 when compared to groups 1 and 2 (0.096 8 0.016, 0.024 8 0.009 and 0.032 8 0.014, respectively; p ! 0.05). There was no statistically significant difference between group 3 and group 4 (p 1 0.05). In brain tissue, the number of caspase-8-immunopositive cells was statistically significantly higher in group 3 when compared to groups 1, 2 and 4 (p ! 0.05). There was no statistically significant difference between groups 1, 2 and 4 (p = 0.62).

IHC Examination of Caspase 9. In spiral ganglia and brain tissues, the number of caspase-9-immunopositive cells was statistically significantly higher in group 3 when compared to groups 1, 2 and 4 (p ! 0.05). There was no statistically significant difference between groups 1, 2 and 4 (p 1 0.05).

The number of caspase 3, 8 and 9 immunostaining cells was statistically significantly increased in group 3 (CDDP group) when compared to groups 1, 2 and 4. The immunostaining of caspases is seen in figure 3 . The number of these cells was high in group 4 (CDDP + ALCAR group); however, there was no statistically significant difference between groups 1 (control), 2 (ALCAR) and 4. There was more caspase 9 than caspase 8 activity, especially in brain tissue, though there was no statistically significant difference between caspase 9 and 8 activities.

areas were observed. Some cells have proapoptotic nuclei. Damage of intercellular junctions was observed (fig.4c).
The ultrastructure of spiral ganglion in groups 1, 2 and 4 was normal (fig.5 a, b, d). In group 3, changes in cell shapes and irregular cell membrane, cessation of satellite cell activity and an increase in cytoplasmic degenerative areas were seen (fig.5 c).
The ultrastructure of the brain in groups 1, 2 and 4 was normal (fig.6a, b, d). In group 3, neuronal electron densities, dilatation in endoplasmic reticulum cisternas, perivascular edema and depletion of neuropile and apoptotic neuronal glial cells were seen (fig.6 c). When the ultra-structural findings of the brain, spiral ganglion and organ of Corti were compared between groups, ultrastructural damage was prominent in group 3 rather than in groups 1 and 2. The ultrastructural damage was minimal in group 4 compared with group 3. The fine structure was similar in groups 1, 2 and 4.
Discussion
CDDP is one of the most effective and widely used cytotoxic agents for the treatment of adult and pediatric malignancies [16] . Ototoxicity, neurotoxicity and nephrotoxicity are major dose-limiting side effects of CDDP.

CDDP primarily damages the outer hair cells (OHCs) of the organ of Corti [8, 9, 2426]. With higher doses of CDDP, additional damage occurs in the auditory neurons, stria vascularis and supporting cells [27]. Various methods have been studied in order to prevent these side effects of CDDP [79, 11]. New experimental studies should be done in order to explain the mechanisms of CDDP-induced toxicity to limit them [8, 9, 11]. CDDP causes cell damage by interacting with the DNA chain and triggers some mechanisms that result in apoptosis [26, 28] . Also, it was shown that CDDP-induced toxicity could occur through oxidative stress which causes irreversible cell damage and apoptosis [7 9, 24].

Several agents have been studied for the protection of CDDP-induced toxicity [79] . ALCAR is one of these agents. It is a short-chain ester derivative of L-carnitine and it is synthesized in the human brain, liver and kidney. It is a neuroprotective and antiapoptotic agent for various cell types [1421].

This is the first experimental study where the protective role of ALCAR in CDDP-induced ototoxicity was investigated by audiologic tests, histomorphologic, IHC and ultrastructural examinations, as well as apoptotic pathways. The ototoxic effects of CDDP treatment on the auditory system in rats have been observed by ABR tests. The rats showed significantly higher ABR wave V threshold levels by all stimuli (clicks, 6-kHz and 8-kHz tone burst) compared to the control groups at the 3rd day of CDDP administration (p ! 0.01). This statistical significance was consistent with findings in the literature [29]. Here, in findings which were obtained by IHC and ultrastructural examinations, we showed that CDDP causes cell and tissue damage and induces apoptosis in the brain, hair cells and spiral ganglia cells. Also, findings showed that apoptosis, cell and tissue damage were prominently reduced by concomitant administration of ALCAR and CDDP. CDDP + ALCAR-treated rats showed significant ABR threshold shifts with click stimuli results compared to the control groups (p ! 0.01). CDDP-

treated rats have significantly higher click ABR threshold levels compared with the CDDP + ALCAR group (p ! 0.01).

Apoptosis is an important way of cell death in normal and pathological processes. Apoptotic death of OHCs is a final common pathway in response to a variety of cellular stresses. CDDP ototoxicity is associated with OHC apoptosis in the organ of Corti [24] and in vivo [30, 31]. However, the intracellular pathways remain unknown. The major intracellular apoptotic pathways may be classified according to the type of pro-caspase that is activated. Three main pathways are involved in apoptosis: the extrinsic, the intrinsic and the endoplasmic reticulum stress pathway. The extrinsic pathway mediated by cell death receptors , signaling of the cell surface death receptors, results in the activation of the initiator procaspase 8 [32] . In the mitochondrial/intrinsic pathway , the activation of the initiator pro-caspase 9 is dependent on the mitochondrial signaling pathway [33, 34] . In the intrinsic/mitochondrial pathway, the release of cyto-chrome c from mitochondria leads to activation of caspase 9 and 8, respectively. Once activated, both caspases 8 and 9 further lead to the activation of caspase 3, and then to apoptosis [12, 35] . It has been reported that the inhibition of caspases may prevent ototoxic hair cell death [24, 25, 36] . In our study, apoptotic cell death was high in groups 3 and 4. When comparing these 2 groups, apoptotic cell death was significantly higher in group 3. In the organ of Corti and brain tissues, the number of caspase 3, 8 and 9 immunostaining cells was significantly increased in group 3 (CDDP group) when compared to groups 1, 2 and 4. These findings emphasize the role of the intrinsic/mitochondrial pathway and also the protective role of ALCAR in CDDP-induced apoptosis in the inner ear and brain.

Conclusion

CDDP-related hearing impairment, damage of hair cells, spiral ganglia cells, brain tissue and CDDP-induced apoptosis can be reduced by concomitant administration of ALCAR and CDDP. In this study, it was shown that ALCAR significantly improves CDDP-induced auditory impairment; also, antioxidative and antiapoptotic properties of ALCAR in CDDP ototoxicity were supported by the findings.

Abstract: Improved speech recognition in binaurally combined acoustic-electric stimulation (otherwise known as bimodal hearing) could arise when listeners integrate speech cues from the acoustic and electric hearing. The aims of this study were (a) to identify speech cues extracted in electric hearing and residual acoustic hearing in the low-frequency region and (b) to investigate cochlear implant (CI) users' ability to integrate speech cues across frequencies. Normal-hearing (NH) and CI subjects participated in consonant and vowel identification tasks. Each subject was tested in 3 listening conditions: CI alone (vocoder speech for NH), hearing aid (HA) alone (low-pass filtered speech for NH), and both. Integration ability for each subject was evaluated using a model of optimal integration-the PreLabeling integration model (Braida, 1991). Only a few CI listeners demonstrated bimodal benefit for phoneme identification in quiet. Speech cues extracted from the CI and the HA were highly redundant for consonants but were complementary for vowels. CI listeners also exhibited reduced integration ability for both consonant and vowel identification compared with their NH counterparts. These findings suggest that reduced bimodal benefits in CI listeners are due to insufficient complementary speech cues across ears, a decrease in integration ability, or both.

Purpose: Improved speech recognition in binaurally combined acoustic-electric stimulation (otherwise known as bimodal hearing) could arise when listeners integrate speech cues from the acoustic and electric hearing. The aims of this study were (a) to identify speech cues extracted in electric hearing and residual acoustic hearing in the low-frequency region and (b) to investigate cochlear implant (CI) users' ability to integrate speech cues across frequencies.

Method: Normal-hearing (NH) and CI subjects participated in consonant and vowel identification tasks. Each subject was tested in 3 listening conditions: CI alone (vocoder speech for NH), hearing aid (HA) alone (low-pass filtered speech for NH), and both. Integration ability for each subject was evaluated using a model of optimal integration-the PreLabeling integration model (Braida, 1991).

Results: Only a few CI listeners demonstrated bimodal benefit for phoneme identification in quiet. Speech cues extracted from the CI and the HA were highly redundant for consonants but were complementary for vowels. CI listeners also exhibited reduced integration ability for both consonant and vowel identification compared with their NH counterparts.

Conclusion: These findings suggest that reduced bimodal benefits in CI listeners are due to insufficient complementary speech cues across ears, a decrease in integration ability, or both.

Key Words: bimodal hearing, speech perception, cross-frequency integration

(ProQuest: ... denotes formulae omitted.)

Cochlear implants (CIs) have evolved from being a supplemental aid to speechreading with a singlechannel system to an auditory aid that provides sufficient speech cues for users to enjoy high levels of speech recognition without visual cues. As a result, audiological requirements for implant candidacy have been relaxed fromprofound to moderately severe hearing loss. Many recently implanted users have some degree of lowfrequency residual hearing. Patients with greater residual hearing in the low frequencies could benefit from a short-electrode CI array to preserve the residual hearing in the implanted ear (this is known as hybrid hearing). More commonly, patients with more severe hearing loss are implanted with a long-electrode array in one ear and use a hearing aid (HA) in the opposite ear (termed bimodal hearing). Although this supplement has been found to be beneficial to speech recognition when combined with electrical stimulation, the types of speech cues in lowfrequency residual acoustic hearing and the abilities of CI listeners to extract and integrate these cues with the electrical signals are not well understood.

Some studies demonstrated significantly better speech recognition performance in quiet with bimodal hearing compared with CI alone (Armstrong, Pegg, James, &Blamey, 1997; Ching, Psarros, Hill, Dillon, &Incerti, 2001; Dooley et al., 1993; Gifford, Dorman,McKarns, &Spahr, 2007; Shallop, Arndt,&Turnacliff, 1992; Zhang, Dorman, &Spahr, 2010), but others have reported no significant combined benefit in the majority of their subjects (Dunn,Tyler,&Witt, 2005;Hamzavi, Pok, Gstoettner, &Baumagartner, 2004; Mok, Grayden, Dowell, &Lawrence, 2006) and even incompatibility between the two devices in some patients (Tyler et al., 2002). Results for speech recognition in noise, on the other hand, are more consistent across studies. Many studies reported combined acoustic-electric benefit for both bimodal and hybrid hearing when both speech and noise were presented from the front (e.g., Ching, Incerti, &Hill, 2004; Dorman, Gifford, Spahr, &McKarns, 2008; Gifford, Dorman, McKarns, &Spahr, 2007; Kong, Stickney, &Zeng, 2005; Mok et al., 2006; Mok, Galvin, Dowell, &McKay, 2009; Turner, Gantz, Vidal, Behrens, &Henry, 2004; Zhang et al., 2010). However, the amount of benefit still varied among listeners. The sources of intersubject variability in bimodal/hybrid outcomes are unclear. It is often assumed that the greater the amount of residual hearing, the greater the bimodal benefit. However, Ching et al. (2004) and Gifford, Dorman, McKarns, and Spahr (2007) failed to find a significant correlation between the unaided threshold below 1000 Hz and the amount of bimodal benefit. Some researchers measured other aspects of auditory function, such as frequency selectivity and modulation detection in patients who are considered

candidates for a CI, but found no correlation between residual functional abilities and speech recognition (Gifford, Dorman, Spahr, &Bacon, 2007).

The possible underlying mechanisms for improved speech recognition performance in bimodal hearing include (a) better detection of the target speech for sentence recognition in noise by glimpsing the target during the spectral and/or temporal dips of the masker (Brown &Bacon, 2009a; Kong &Carlyon, 2007; Li &Loizou, 2008) and (b) integration of speech cues between electric stimulation and acoustic stimulation at low frequencies (e.g., Ching et al., 2001; Ching, van Wanrooy, &Dillon, 2007; Kong&Carlyon, 2007). The glimpsing mechanism has been studied in recent years; however, speech cue integration in bimodal hearing has not received much attention. In the present study, we investigated the ability of bimodal subjects to integrate speech cues across ears and across devices. The variability in the amount of combined benefit (Dunn et al., 2005; Mok et al., 2006; Hamzavi et al., 2004) could be attributed to the variability in the integration ability among CI users.

Integration of speech cues from multiple modalities or sources (Braida, 1991; Grant, 2002; Grant &Seitz, 1998; Massaro, 1987, 1998; Massaro &Cohen, 2000; Ronan, Dix, Shah,&Braida, 2004) has been researched and discussed extensively. Several quantitative models have been developed to characterize the processes of multimodal integration of speech segments and to predict integration performance based on observed performance for each separate modality. These models make predictions based on the observed confusion matrix (Miller &Nicely, 1955) for each separate source. The models assume that cues in each source are statistically independent from each other, that they combined without interference, and that no new cues arise from intersource comparisons. Among them, the PreLabeling (PreL) model of integration developed by Braida (1991) predicts combined-source scores using an "optimal" decision rule that assumes perfect integration of the cues derived from each separate source. The difference between observed combined scores and predicted combined scores obtained by this ideal observer model allows us to evaluate a listener's ability to integrate cues fromvarious sources, independent of his or her ability to extract cues from each separate source. A detailed description of the PreL model is provided in the Results section of Experiment II. Although the integration models were developed to describe perceptual integration based on audiovisual speech reception research, they have been formulated abstractly and have been shown to be capable of describing the integration of auditory cues across spectral bands (Grant,Tufts,&Greenberg, 2007; Ronan et al., 2004). In Ronan et al. (2004), the evaluation of predictions by a number of models for crossfrequency integration was performed with speech cues combined from different frequency bands. The authors first divided broadband speech into five discrete frequency bands (0-700 Hz; 700-1400 Hz; 1400-2100 Hz; 2100-2800 Hz; and 2800-4500 Hz) and then combined the bands that were adjacent to each other or remotely apart. The number of frequency bands was one of the testing variables. The authors concluded that both the PreL integration model and the fuzzy logical model of perception were able to predict performance for various combinations of frequency bands tested,with only a few exceptions.

To receive maximal benefit from multisensory or multisource stimulation, listeners need to be able to extract complementary cues from each source and to integrate the cues from all sources (Braida, 1993). The PreL model conceptualizes cue extraction and cue integration as two independent processes. Therefore, predictions from the model allowed us to examine each factor separately. The subsections that follow discuss each of the two factors.

Information Extraction

The type and amount of speech cues provided by each source of stimulation can affect the degree of combinedsource benefit. When comparing two different stimulation conditions, Grant,Walden, and Seitz (1998) demonstrated that the condition resulting in the highest recognition scores does not necessarily result in the highest combined score or the greatest improvement when combining the sources. Braida (1993) described twoextremecases: (a) the sources provide cues that complement one another and (b) the cues provided by each source are completely redundant with one another. If speech cues in each stimulation condition are

redundant, combined-source benefits will be less than if the cues are complementary.

Information Integration

Cue extraction and integration are considered independent processes in the integration models described above. According to thesemodels, it is possible tomeasure multisensory integration that is independent of abilities to extract cues from each source. In other words, listeners' ability to integrate cues in a multisource condition is not affected by the type and amount of cues extracted from each source. All other things being equal, it is assumed that greater ability to integrate speech cues from different sources will yield better performance in the combined-source condition.

Within this framework, the variability in bimodal outcomes (particularly in quiet) among CI users could be attributed to a decreased ability to extract speech cues and/or a reduced ability to integrate speech cues. This has been shown in cross-frequency integration in hearingimpaired (HI) and elderly listeners (Grant et al., 2007; Healy &Bacon, 2002; Palva &Jokinen, 1975; Turner, Chi, &Flock, 1999). Using the PreL model, Grant and colleagues (2007) examined cross-frequency cue extraction and cue integration abilities in a group of HI listeners. They reported that HI listeners showed proportionally less benefit than normal-hearing (NH) listeners when additional high-frequency cues were added to the lowfrequency speech. They attributed the reduced benefit to HI listeners' difficulty extracting cues from the highest frequency band (4762-6000 Hz) when presented concurrently with the lower frequency band (1890-2381 Hz), as well as their inefficiency in integrating speech cues across frequency regions.

The present study was the first attempt at applying an integration model to understand the process by which speech cues are integrated in combined acoustic-electric stimulation. We first measured phoneme (both consonants and vowels) recognition performance in bimodal CI listeners to examine the redundancy of speech cues extracted from electric stimulation and acoustic stimulation in the low-frequency region. Then, we used the modelbased approach to investigate and compare NH and CI listeners' ability to integrate cross-frequency speech cues.

Experiment I: Cross-Frequency Integration in NH listeners

The PreL integration model has shown the ability to predict performance for auditory-visual integration (Braida, 1991, 1993; Grant et al., 1998) and auditory integration across frequencies for consonant identification (Grant et al., 2007; Ronan et al., 2004). In this experiment, we set out to further evaluate the application of the PreL model to predict a combined-band performance that was created to simulate bimodal hearing, in which low-frequency (<1000 Hz) speech was delivered to one ear, andwideband (200-6000 Hz) vocoder-processed speech was delivered to the opposite ear.

Preliminary Study

Before the start of this experiment, we conducted a preliminary study that assessed the model fit to a unique combined-band performance that was not examined in Ronan et al. (2004). In Ronan et al.'s study, multisource speech cues came from nonoverlapping frequency bands. The purpose of this preliminary study was to demonstrate that the PreL model is capable of predicting combinedband performance when the speech signals from different frequency regions undergo different signal processing (low-pass [LP] filtering with cutoff frequency at 500 Hz and channel vocoding above 900 Hz). Because this preliminary study is not the focus of this article, a brief description of the methodology and results from our model predictions is included in the Appendix.

Method

Subjects. Eight NH subjects (7 females, 1 male) 19-31 years of age participated in the study. Six subjects participated in the consonant identification task, and six subjects participated in the vowel identification task. Four of the subjects participated in both tasks.

Stimuli. Two sets of speech stimuli were used. The first set consisted of 16 consonants (/p, t, k, b, d, g, f, θ, s, ʃ, v, ð, z, ..., m, n/) used by Miller and Nicely (1955) in the /aCa/ context. These stimuli were recorded by five male and five female talkers by Shannon, Jensvold, Padilla, Robert, and Wang (1999). The second set consisted of

nine monophthongs (/i, I, ε, æ, 3, Lgr;, u, ..., c/) in the /hVd/ context recorded from five male and five female talkers in our laboratory. All stimuli were scaled to the same overall root-mean-square (RMS) level. For each stimulus set, recordings from two male and two female talkers were used in the practice sessions, and recordings from the remaining six talkers were used in the test sessions. Three utterances of each consonant and vowel from each talker were used.

Recorded stimuli were subjected to two types of processing: LP filtering and channel-vocoding. LP was performed using Butterworth filters with a rolloff of 60 dB/octave and a cutoff frequency of 500 Hz. These LP parameters mimicked a sloping hearing loss above 500Hz, an audiometric configuration commonly seen in real bimodal CI users. Channel-vocoding processing preserved speech cues from 200 Hz to 6000 Hz. The vocoder system simulated listening with a long-electrode array CI device. In this system, broadband speech (200-6000 Hz) was first processed through a pre-emphasis filter and then band-pass filtered into four logarithmic frequency bands. The lower, center, and upper frequencies of the band-pass filters for this four-channel vocoder condition are listed inTable 1. Theamplitude envelope of the signal was extracted from each band by full-wave rectification and LP with a 400-Hz cutoff frequency. Sinusoids were generated with amplitudes equal to the RMS level of the envelope and frequencies equal to the center frequencies of the band-pass filters. The sinusoids were then summed and presented to the listeners.

Procedure. Subjects were tested in a double-walled soundproof booth. Stimuli were presented from a sound card using 16-bit resolution at 44.1-kHz sampling rate to Sennheiser HD 265 headphones. Each subject was presented with two different speech signals: low-frequency (LP speech) to one ear and vocoder speech to the opposite ear. Three types of listening conditions were tested: lowfrequency speech alone (LP-alone), vocoder speech alone (vocoder-alone), or LP and vocoder speech combined (LP+vocoder). For both consonant and vowel identification tasks, half of the subjects were presented with vocoder stimuli to the left ear and LP stimuli to the right ear; the remaining half received the stimuli on the opposite sides. All stimuli were presented at an RMS level of 70 dBA.

For each condition, listeners first received practice trials identifying the consonant and vowel with visual correct-response feedback provided. Performance usually reached a plateau (i.e., within 3 percentage points difference) within three blocks of practice. If not, additional practice was given until the criterion was met. Each subject was then tested in blocks of 96 trials (16 consonants ×6 talkers) for consonant identification, and 54 trials (9 vowels ×6 talkers) for vowel identification. Each utterance from each talker was used for three blocks of testing. Nine blocks of testing were presented in each test condition, yielding 54 trials (6 talkers ×9 blocks) per stimulus per condition per subject. No feedback was provided during test sessions. The order of presentation of the listening conditions was counterbalanced across subjects. Stimuli within each block were presented in random order. A list of 16 /aCa/ or nine /hVd/ syllables was displayed on a computer screen, and subjects responded by clicking a button corresponding to the syllable that they heard. Consonant and vowel confusion matrices were constructed from each subject's responses.

Data Analysis and Model Fits

The mean overall percent correct scores were calculated for consonant and vowel identification tasks. In addition, based on the confusion matrices of the group data, information transmission (Miller &Nicely, 1955) was computed for the features of voicing, manner of articulation, and place of articulation for consonant identification for each test condition. This was also done for the features of height, back, and tense for vowel identification. The different consonant and vowel features are listed in Table 2.

Model predictions for combined scores were made for each subject using the PreL model of integration (Braida, 1991). The model first analyzes observed confusion matrices for each separate source of information (i.e., LP speech vs. vocoder speech) and then makes predictions for the confusion matrix when these sources are presented simultaneously, using an "optimal" decision rule that assumes perfect integration of available cues in an ideal observer without any bias. The PreL model is a special form of multidimensional scaling (MDS) and a

multidimensional extension of the signal detection theory. Unlike traditional MDS, the scaled distances between stimuli in separate source spaces are converted into a common metric, d. It is assumed that there is a D-dimensional vector of cues ... associated with each presentation of one of the N possible consonants Si. The cue vector X is described by the conditional probability density

... (1)

and may be thought of as displaced fromthe stimulus center .... Corresponding to each response, there is a response center or prototype .... The decision processes assume a comparison between the stimulus attributes (i.e., the observed vector of cues X) and the response center Ri in memory. The listener is assumed to respond Rk if and only if the distance from the observed vector of cues X to Rk is smaller than the distance to any other prototype-that is, ... A listener's sensitivity d'(i, j) in distinguishing stimulus Si from stimulus Sj is given by

... (2)

where ... is the distance between theD-dimensional vector of cues generated by stimuli Si and Sj. The predictions for the multisource condition (i.e., dichotic presentation of LP and vocoder speech) are made based on the performance in the single-source conditions (i.e., LPalone and vocoder-alone). In the multisource condition, the model assumes that cues in each source are statistically independent from each other, that they are combined without interference, and that no new cues arise fromintersource comparisons. Integration of cues ismodeled by assuming that the cue densities are the "Cartesian products" of the densities corresponding to the separate sources. In the multisource condition, the cue space has dimension DAB = DA + DB, and each stimulus center Si has the coordinates

... (3)

This model for the multisource condition predicts that there is a simple Pythagorean relationship between a subject's sensitivity in themultisource condition, d'AB(i, j), and the corresponding source sensitivities d'A(i, j), and d'B(i, j):

... (4)

In this model, the configurations derived from the single-source confusion matrices determine the predicted stimulus centers for the multisource configurations. Prediction accuracy in themultisource condition also requires a specification of the response centers (i.e., the prototypes). In thePreLmodel described byBraida (1991), the response centers of the multisource condition were assumed to coincide with the multisource stimulus centers. In recent work, Ronan et al. (2004) evaluated the locations of the response centers inthe multisource case for cross-frequency consonant identification in NH listeners. In that study, cross-frequency consonant identification performance in the multiband case was made with three different assumptions of the location of the multiband response centers: PreLI0, PreLI1, and PreLIH.

PreLI0

The response centers in the multisource case are the Cartesian products of the response centers in the singlesource case. As mentioned in Ronan et al. (2004), this assumption represents a case of minimal adjustment(s) to the multisource stimulation condition, in which the response centers are located at the same locations they had in the single-source conditions. This implies thatwhen provided with multisource stimulation, listeners elicit a response that concurs with the response from a single source-that is, HA-alone or CI-alone conditions in the present study.

PreLI1

The response centers in the multisource case coincide with the multisource stimulus centers. This assumption predicts optimal integration of cues from different sources and predicts maximum overall performance. As Grant and colleagues (1998, 2007) pointed out, because the PreL model is an optimal integration model, predicted scores should always be higher than or equal to the observed scores in real listeners if no new cues arise from the simultaneous presentation of multiple sources.

PreLIH

The response centers in the multisource case are halfway between the response centers in the single-source case and multisource stimulus centers. As pointed out by Ronan et al. (2004), this represents an intermediate case of adjustment to the multisource condition in which the response centers are halfway between the response centers in Case A and Case B.

In this study, we made the predictions for the combined LP and vocoder performance using these three assumptions to examinewhere listeners place theirmultisource response centers. For example, if the listener's multisource response centers coincide with the multisource stimulus centers, the PreLI0 method and the PreLIH method will provide predictions that underestimate the observed scores, whereas the PreLI1 model will provide predictions equal to or slightly higher than observed scores. If listeners' multisource response centers are located at the same locations as in one of the single-source conditions-suggesting a potential reduced integration ability or response bias-the PreLI0 assumption will provide predictions close to observed scores, whereas the PreLIH and the PreLI1 assumptions will overpredict by a greater extent. The evaluation of the model fit with these three assumptions will be based on (a) overprediction or underprediction of the observed data and (b) the amount of error between predicted and observed scores. Given that the PreLI1 model is an ideal observer model, a model fit is expected to overestimate real human observers' scores. Thus, the model that estimates the observed scores with a smaller amount of error is considered the best fit compared with those that produce greater error between the predicted scores and the observed scores.

Results

Phoneme Identification and Information Transmission

Consonant identification. Figure 1 shows the mean overall percent correct consonant identification (left) for three listening conditions. Paired t-tests on the arcsinetransformed data revealed a significant combined benefit of 5.6 percentage points compared with vocoder alone in NH listeners, paired $t(5) = 7.37$, $p < .001$, suggesting that NH listeners are able to integrate LP and vocoder speech cues across ears.

Percent information transmission for the consonant features voicing, stop, nasal, fricative, and place of articulationwas calculated for theNHgroup data (see Figure 2, left panel). The group data were computed from confusion matrices combined across subjects. First, there was substantial cue redundancy between LP-alone and vocoderalone stimuli. Unlike the complementary cues provided by the auditory (voicing and manner of articulation) and visual (place of articulation) stimuli in combined auditory-visual stimuli, the LP speech provided cues- mostly, voicing and manner of articulation-that were largely redundant to those delivered by the vocoder speech. However, all features except for place of articulation were transmitted above 80% by the vocoder. Second, the presence of the combined benefit of LP+vocoder speech over vocoder speech alone is noticeable for voicing, fricative, and place-of-articulation features but not for stop and nasality, perhaps due to a ceiling effect. The amount of improvement ranged from 5 to 8 percentage points. This pattern of results is similar to that found in our preliminary study (see Appendix). Taken together, these results suggest that NH listeners are able to combine consonant features across ears and across frequencies to improve their overall consonant identification performance as reported in Ronan et al. (2004).

Vowel identification. Overall mean vowel identification for NH listeners was computed and compared between combined and vocoder-alone conditions (see Figure 1). Paired t-tests on the arcsine-transformed data revealed a significant combined benefit of 15.6 percentage points compared with vocoder-alone conditions for vowel identification, paired $t(5) = 9.60$, $p < .001$, suggesting that NH listeners are able to integrate LP and vocoder speech cues across ears for better identification of vowels. The amount of the combined benefitwas greater for vowel identification than for consonant identification.

Percent information transmission was computed for three vowel features (Chomsky &Halle, 1968): height (high, mid, low), back (front, central, back), and tense (tense, lax). Acoustically, the first formant (F1) is associated with the height of the vowel (F1 increases as the vowel height decreases). F1 frequencies for American vowels are generally below 1000 Hz for adult talkers (Hillenbrand, Getty, Clark, &Wheeler, 1995), which is within the

range of the LP stimuli. Results fromthe acoustical analysis of our stimuli are consistent with this finding. The second formant (F2), on the other hand, is associated with the backness of the vowel (F2 decreases as the production of the vowelmoves toward the back of the vocal tract), which normally occurs at a higher frequency region (>900 Hz; Hillenbrand et al., 1995). This wasalso confirmedbythe acoustical analysis onour stimuli. The difference between tense and lax vowels is based on an articulatory criterion of muscular tenseness or laxness. Acoustically, tense and lax vowels generally differ in terms of their durations and F1 frequencies. Figure 2 (right panel) shows the average percent information transmission for these three vowel features. It is not surprising that only a small amount of information about the feature back was transmitted by the LP speech-which only contained frequencies up to 1000Hz- below the frequency range of F2 in most vowels. About 31% of information regarding vowel height was delivered to the listeners with the LP speech. A closer examination of the confusion matrix reveals that confusions occurred more frequently between high lax vowels (e.g., /I, .../) and mid vowels (...) as well as between mid vowels and low vowels (e.g., /æ /). In these cases, the F1 frequencies of these vowels were generally closer to each other, suggesting that listeners were able to distinguish the vowel height when F1 differences were large. Information transmission for the feature tense by the LP stimuli was 74%, significantly higher than the feature vowel height. This may be because listeners can use both durational and F1 cues to distinguish tense vowels from lax vowels. Percent information transmission for the vowel feature "height" for four-channel vocoder speech was 39%, for the vowel feature "back" was 48%, and for the vowel feature "tense" was 60%.

Similar to the consonant identification results, the combined benefit of LP+vocoder speech compared with vocoder-alone is seen for the three vowel features evaluated in this study. The combined benefit was 26, 13, and 16 percentage points for the vowel features height, back, and tense, respectively. It is noted that this pattern of results is also similar to that in our preliminary study. These findings suggest thatNHlisteners are able to combine vowel features across ears and across frequencies to improve their overall vowel identification performance.

Model Predictions for NH Listeners

Integration ability across frequencies was evaluated using the PreLI0, PreLI1, and PreLIH integration models that differ in terms of the location of the response centers in the multisource condition described in Ronan et al. (2004).

Consonant identification. Predictions weremade separately for each subject and condition. We made the predictions by first fitting the vocoder-alone and LP-alone matrices in D = 3 dimensions and then predicting the scores for the combined condition from a six-dimensional (6-D) model. Figure 3 (upper left panel) shows the predicted versus observed combined-source consonant identification scores for each response center location (triangles = PreLI0; squares = PreLI1; circles = PreLIH). The unityslope line represents a perfect match between predicted and observed scores. Points falling above this line indicate that the predicted scores are better than the observed scores and vice versa. Since PreLI1 made predictions using an "optimal" decision rule that assumes perfect integration of cues from each source, predicted scores are expected to be equal to or greater than observed scores. As expected, PreLI1 constantly overpredicted the observed combined performance (by an average of 9.1 percentage points). PreLI0 consistently underpredicted the combined performance by an average of 7.2 percentage points, whereas PreLIH overpredicted the combined performance by an average of 4.6 percentage points. The deviation between predicted and observed scores, calculated as root-mean-square error (RMSE), was greater for PreLI0 (8.7 percentage points) than for PreLIH (5.1 percentage points). In general, this pattern of results is similar to those reported in Ronan et al. (2004) for cross-frequency integration (across or within the same ear) as well as those from our preliminary study for consonant identification inNHlisteners,which also showed that PreLI0 underestimated the multiband scores and that PreLIH provided better predictions compared with PreLI1 (i.e., overpredicted, to a lesser extent) for cross-frequency consonant identification. The consistent underestimation of combined performance by PreLI0 and the more accurate

predictions (i.e., smaller errors between predicted and observed scores) by PreLIH suggests thatNH listeners indeed integrated cues from both LP and vocoder speech and that the locations of the response centers in the combined condition were different from those in the original LP-alone or vocoder-alone response centers.

Vowel identification. Predictions for vowel identification were made in the same way as for consonants for each subject and combined condition. The vocoder-alone and LP-alone matrices were first fit with three dimensions; then, the combined scores were fit with a 6-Dmodel. Figure 3 (upper right panel) shows the predicted versus observed combined-source vowel identification scores for each response center location (triangles = PreLI0; squares = PreLI1; circles = PreLIH; note that some data points overlap on this graph). Consistent with consonant identification results, PreLI1 constantly overpredicted the observed combined performance (by an average of 7.0 percentage points).PreLI0 consistently underpredicted the combined performance by an average of 6.9 percentage points, whereas PreLIH overpredicted the combined performance by an average of 3.6 percentage points. The deviation (RMSE) between predicted and observed scores was greater for PreLI0 (8.4 percentage points) than for PreLIH (4.5 percentage points).This pattern of results is, again, consistent with that found in our preliminary results for the vowel identification task (see Appendix).

Experiment II: Cross-Frequency Integration in Bimodal CI Users

There has been no systematic investigation that examined CI listeners' ability to extract and integrate speech cues across electric and acoustic stimulation. Ching et al. (2001) calculated information transmission for consonant recognition but did not investigate vowel recognition. Mok et al. (2006) used consonant-nucleus-consonant (CNC) phoneme recognition scores to calculate information transmitted in individual ears and combined hearing and reported that differences in scores between bimodal hearing and CI alone were greatest in phonemes containing relatively low-frequency cues compared with phonemes containing high-frequency cues. In the present study, CI listeners were tested with the same stimuli and procedures as those used for NH listeners to facilitate comparisons of performance between the two groups. In addition, we acquired a large number of repeated measures (42-54 trials) for each bimodal CI listener per stimulus per listening condition, which was rarely done in previous studies. This was necessary in order to minimize estimation bias for the analysis of information transmission (Sagi &Svirsky, 2008).

Method

Subjects.Twelve CI subjects (C1-C12; seven females, five males) 15-69 years of age (M = 35.75 years) participated in the consonant identification task, and half of them (C2, C5, C7, C8, C9, and C12) also participated in the vowel identification task. Table 3 shows detailed demographic information for each subject, including age, onset of hearing loss, etiology of hearing loss, duration of severe to profound hearing loss prior to implantation, and the CI processor used. Seven subjects were under the age of 30 years, close to the age range of the NH subjects in Experiment I. The remaining subjects were in the age range from 46 to 69 years. Seven subjects are congenitally hard of hearing bilaterally (C4, C5, C7, C9, and C11) or were diagnosed with bilateral hearing loss at a very young age (C3 and C8) but had enough residual hearing to receive benefits from HA use before they received a CI. Of these seven subjects, three subjects (C3, C7, and C8) have hearing loss that was progressive from (a) mild to (b) severe to profound. The other four subjects had a severe hearing loss at birth (C4, C5, C9, and C11). Two subjects are congenitally deaf or acquired hearing loss at a young age in only one ear (C10 and C12). They subsequently acquired hearing loss in the other ear later in life (C10 at age 7 years; C12 at age 43 years). All subjects use oral communication and have developed normal language skills. Speech production is highly intelligible in all subjects. All subjects wore their HA in the implanted ear before their implant surgery (except for C10), and they all continued to wear their HA in the nonimplanted ear on a daily basis after implantation. Figure 4 shows the unaided (upper panel) and aided (lower panel) thresholds in the nonimplanted ear for each individual, except for Subject C6 due to lack of audiological data and lack of audiometric equipment on the day of the test. The threshold data were obtained either from subjects' most recent audiologic examination or on the same day of the testing in our laboratory. A large variability in the

amount of residual hearing was evident in this subject group. Although some subjects (e.g., C2) have mild to severe hearing loss at the low frequencies (<1000 Hz), some (e.g., C11) have profound loss even in the lowest frequencies. With amplification, all subjects have aided thresholds in the mild to moderate hearing loss range below 1000 Hz.

Stimuli and procedure. The unprocessed consonant and vowel stimuli in Experiment I were used for CI listeners. Each subject was evaluated under three listening conditions: HA-alone, CI-alone, and combined use of a CI and a HA (CI+HA). All stimuli were presented via a loudspeaker 1 m directly in front of the subject at a fixed level of 65 dBA. Subjects used their own CI and HA settings during the entire test session, except for the volume setting in the HA. Subjects adjusted the volume of their HAs until the presented stimuli reached their comfortable listening level. Those who could not achieve the comfortable level with the HA alone were asked to adjust the volume of their HA to the maximum setting before any distortion occurred. With this setting, they reported that the presented speech stimuli were just slightly below the comfortable level. The same HA and CI settings were used for the CI+HA condition for each subject. Given that the purpose of this study was to investigate listeners' ability to integrate speech cues, we used subjects' everyday device settings to minimize novelty effects, which are likely to affect integration ability.

Subjects were asked to turn off their CI when tested on the HA-alone condition. They were instructed to turn off their HA but leave their earmold in place in the nonimplanted ear when tested on the CI-alone condition. A foam earplug was inserted in the implanted ear during testing regardless of the listening condition to prevent any potential acoustic stimulation in case residual hearing was preserved in that ear. To verify that the earmold and the foam earplug provided sufficient attenuation to completely eliminate any acoustic stimulation, prior to the experiment, each subject was instructed to turn off both the HA and CI and have both the earmold and the foam earplug inserted into their ear canals. Test speech stimuli (10 tokens) were then presented at 65 dBA via the loudspeaker. Under this condition, none of the CI listeners reported hearing any sound.

As in Experiment 1, each CI listener first received practice identifying the consonants and vowels with visual correct-response feedback provided for each test condition. Performance usually reached plateau (i.e., within 3 percentage points' difference) within three blocks of practice; additional practice sessions were given until the criterion was met. After the practice sessions, each CI listener was then given nine blocks (3 blocks for each of the three utterances) of testing for each test condition, yielding a total of 54 trials (6 talkers ×9 blocks) per stimulus per condition per subject, except for subjects C1 and C6, who were tested with only seven blocks (42 trials per stimulus per condition) due to time constraints. No feedback was provided during test sessions. The order of testing for the CI-alone and CI+HA conditions was counterbalanced across subjects (i.e., half of the subjects were tested with the CI-alone condition first and vice versa). The HA-alone condition was tested last. This was done intentionally to minimize any anxiety arising if the subjects performed poorly with their HA alone.

Results

Phoneme Identification and Information Transmission

Consonant identification. Overall consonant identification was calculated for each subject and listening condition (see Figure 5, upper panel). There was a large intersubject variability in scores, ranging from a nearchance level of 15%-16% correct (C8 and C11) to a highlevel performance of 78% correct (C3) for the HA-alone condition, and ranging from 32% (C12) to 87% correct (C5) for the CI-alone condition. Two subjects, C8 and C11, could not perform the task with HA alone: Their scores were near chance levels of 16%. The majority of the subjects showed significantly better consonant identification with CI alone than with HA alone ($p < .05$), except for C4 and C12. Subject C4 showed no significant difference in performance between the HA-alone and CIalone conditions, $t(16) = 1.94$, $p = 0.07$. Subject C12 performed significantly better with HA alone than with CI alone, $t(16) = 14.18$, $p < .001$. Unlike the patterns of results obtained in NH listeners, the majority of CI listeners did not show a bimodal benefit (i.e., the CI+HA consonant identification scores were not significantly different from the scores for the better ear), except for C3. The bimodal benefit (CI+HAvs. CI-alone) noted in C3was 3.8

percentage points. Subject C9, however, showed a significant decrease in performance (4.1 percentage points) with combined CI and HA use compared with CI alone, $t(16) = 3.95$, $p < .005$. An asterisk denotes significant difference between the CI+HA score and the better-ear score.

The group mean data is also shown in Figure 5. We excluded Subject C12 in the group analysis because of her atypical pattern of results. Although consonant identification was better in the CI+HA condition than in the CI-alone condition in C12, her bimodal hearing performance was no better than her HA-alone performance. The inclusion of this subject in the group analysis could produce a false impression that there was a bimodal benefit compared with listening to a single device (HA alone or CI alone).

Percent information transmission for the consonant features of voicing, stop, nasal, and fricative as well as for place of articulation was calculated for each subject and for the group data (see Table 4). The group data were computed from confusion matrices combined across subjects, excluding Subject C12. The HA provided information about voicing and nasality but very limited information about stops, fricatives, and place of articulation. On average (excluding C12), CI alone provides 56% voicing information, which is consistent with findings reported in the literature (e.g., Ching et al., 2001; Fishman, Shannon, &Slattery, 1997). Unlike the patterns of results from NH listeners-which showed improvement in the combined conditions compared with the vocoder-alone condition on some consonant features- there was no sizable bimodal benefit for all consonant features in the CI group, except for an 8.9-point improvement in the nasality feature.

Vowel identification. Overall vowel identification scores were calculated for individual and group mean data (excluding C12) for each listening condition (see Figure 5, lower panel). Only one subject, C12, showed better vowel identification with HA alone compared with CI alone, $t(16) = 16.68$, $p < .001$. The rest of the group showed a reverse pattern. Unlike the lack of bimodal benefits for consonant identification, half of the subjects tested (C2, C5, and C8) showed a bimodal benefit of 3.5-6.8 points for vowel identification compared with CI alone or HA alone ($p < .05$). The bimodal benefit does not seem to correlate with the amount of residual hearing in the nonimplanted ear. For example, despite the fact that Subjects C8 and C9 had almost identical hearing loss from 250 Hz to 1000 Hz, Subject C8 showed bimodal benefit, and Subject C9 did not.

Percent information transmission was calculated for the three vowel features-height, back, and tense-for individual and group data (excluding C12) for each listening condition (see Table 5). The type and amount of information transmitted by the HAwere very similar to those obtained in LP-alone condition in NH listeners. CI listeners also performed similarly to NH listeners listening to four-channel vocoder stimuli. As a group (excluding C12),HA alone provided more information on the vowel height (F1; 27%) but essentially no information on the feature back (F2; 4%). CI alone provided more information on the feature back (69%) than on vowel height (53%). This suggests that HA provided complementary information to a CI for vowel identification. Independent of listening condition, vowel tense was better identified than vowel height, suggesting CI listeners' ability to use multiple cues (duration and F1) to distinguish between tense and lax vowels. The three subjects (C2, C5, and C8) who demonstrated a significant bimodal benefit were the only ones who showed better CI+HA performance compared with CI-alone performance on all three vowel features. The lack of improvement between CI+HA and CI-alone or HA-alone on vowel features height and back was seen for subjects (C7, C9, and C12) who did not show overall bimodal benefit in vowel identification.

The information transmission analysis provides one test of whether performance of the NH subjects who listened to vocoder speech is a reasonable acoustic model to approximate performance in CI subjects. The patterns of results with vocoder speech alone obtained from NH listeners for both consonant and vowel identification are consistent with those obtained with the CI listeners in this study, as well as results reported in the CI literature (Ching et al., 2001;Mok et al., 2006). For consonants, both vocoder speech and CI alone provided more information on features voicing and manner of articulation than on place of articulation. For vowels, both vocoder speech and CI alone provided more information on the feature back than on vowel height.

Model Predictions for CI Listeners

The ability to integrate electric and acoustic speech cues in CI listeners was evaluated using the PreLI0, PreLIH, and PreLI1 models, and results are compared with those obtained from NH listeners. Similar to the fitting procedures used for theNHdata, CI datawere first fit with a 3-D model on the HA-alone and CI-alone matrices and then was fit with a 6-D model for the bimodal performance for both consonant and vowel identification.

Consonant identification. Figure 3 (lower left panel) shows predictions for individual CI subjects for the bimodal hearing condition. Triangles represent predictions from PreLI0, squares represent predictions from PreLI1, and the circles represent predictions from PreLIH. Note that we were unable to model the data for Subject C2. In order to apply the model to the data, errors must be made in identifying the stimuli. This subject made no errors for one stimulus. Our modeling results show that the predictions of the PreLI0 model were either equal to or just slightly higher (1.3-4.6 points) than the combined scores for eight subjects.The PreLI0 model underpredicted the combinedscores for three subjects-C7,C8, and C11- by only 6.1, 6.3, and 9.7 percentage points, respectively. This is very different than the patterns of results seen in NH listeners, in which PreLI0 almost always underpredicted the combined score (see upper left panel of Figure 3). PreLI1 and PreLIH, on the other hand, overpredicted the combined score by a greater amount, ranging from 8.5 points (C5) to 35.2 points (C1) for PreLI1, and 5.2 points (C11) to 21.8 points (C1) for PreLIH. In sum, the data for the CI listeners, unlike those for theNHlisteners,were better fit with response centers located somewhat nearer to the original response centers in the single-source condition. This suggests that the majority of the CI listeners (except for three subjects: C7, C8, and C11) made minimal adjustment to the bimodal hearing condition, and their responses to the bimodal stimulation were similar to the responses made to theHA-alone or CI-alone condition-whichever produced higher overall performance.

Vowel identification. Figure 3 (lower right panel) shows the predicted versus observed combined vowel scores for six CI listeners usingPreLI0 (triangles),PreLI1 (squares), and PreLIH (circles) models. Although PreLI0 consistently underpredicted the bimodal performance in NH listeners, it produced mixed results for the CI listeners-an underprediction for half of the six subjects tested (C2, C5, and C8). It should be noted that the three subjects (C2, C5, and C8) for whom PreLI0 underpredicted combined scores are the same subjects who achieved significantly higher overall vowel identification scores with bimodal hearing compared with CI alone. The rest of the subjects (C7, C9, and C12) who did not receive a bimodal benefit for vowel identification were also best fit by PreLI0, in which the predictions were either equal to (C7) or just slightly higher than (2.3 points for C9 and 4.6 points for C12) the observed combined scores. This finding suggests that these three subjects may not have been able to integrate as well as the other subjects who showed significant bimodal benefit for vowel identification. Both PreLIH and PreLI1 overpredicted the combined scores for all subjects by an average of 6.6 and 9.0 percentage points, respectively.

Discussion

Information Transmission by HA and CI

Information transmitted via the HA and the CI is largely redundant for consonants. Both HA and CI provided greater voicing and manner-of-articulation information but less place-of-articulation information. Note that seven of the 12 CI subjects who were tested achieved voicing scores below 40%-considerably lower than the voicing score obtained from theNH group when only low frequencieswere presented (LP-alone condition).One possibility for the reduced HA performance is that the HA fitting in our CI subjectsmay not be optimal.More likely, the difference in the voicing score is due to the presence of severe to profound hearing loss in the CI listeners, whereas NH listeners have normal low-frequency hearing. At first, the low voicing scores in the impaired ears may seem surprising given that voicing cues are preserved at the low frequencies. However, similar results have been reported in the literature onHI individuals with substantial hearing loss at low frequencies (Boothroyd, 1984; Ching et al., 2001; McDermott, Dorkos, Dean, &Ching, 1999). McDermott et al.

(1999) tested five adults with sensorineural hearing loss on phoneme, word, and sentence recognition tasks. All subjects had moderate to profound sensorineural hearing loss from 500 Hz to 1000 Hz and a profound loss above 1000 Hz.Two subjects had a mild loss at 250 Hz, and the rest had moderate to moderately severe loss at that frequency, very similar to our CI listeners in the nonimplanted ear. With conventional amplification, three of McDermott et al.'s (1999) subjects showed voicing scores below 40%, consistent with our findings. Ching et al. (2001) investigated a group of 16 bimodal CI children (range = 6-18 years of age) who had severe to profound hearing loss in the nonimplanted ear. They reported a low voicing score in the HA-alone condition, with an average voicing score of about 36% in quiet. Careful examination of our data revealed that voicing confusions occurred mostly for fricative consonants. For example, /f/ and /θ/ were frequently misidentified as voiced stop /b/ or voiced fricatives /v, ð, z/; /s/ and /ʃ/ were misidentified as voiced stop /d/ or voiced fricatives /ð, z, .../. The reason for the poor voicing perception in our subjects is unclear.

Unlike consonants, information transmitted via the HA and the CI is somewhat complementary for vowels. The HA received mostly F1 information, but the CI received more F2 information than F1. This finding is consistent with results reported in the literature. Mok et al. (2006) tested a group of bimodalusers onCNCwords in quiet. The degrees of hearing loss in the nonimplanted ears of their subjects were similar to those in our subjects. Mok et al. (2006) reported about a 14-percentagepoint better F1 transmission than F2 on the HA side, and about an 8-percentage-point better F2 transmission than F1 on the CI side.

Bimodal Benefits

Although all NH listeners showed improved consonant and vowel identification in the LP+vocoder condition compared with the vocoder-alone condition, only a few CI listeners showed a bimodal benefit. This pattern of results has been reported previously for bimodal hearing users (Ching et al., 2001; Dunn et al., 2005; Mok et al., 2006) as well as for hybrid users for consonant identification (Reiss, Gantz,&Turner, 2008). Ching et al. (2001) reported that only three out of 11 subjects showed significant bimodal benefit for speech recognition in quiet with HAs that were adjusted to provide the target insertion gain using the prescriptive National Acoustic Laboratories (NAL-RP) method. Dunn et al. (2005) and Mok et al. (2006) reported that only four out of 12 subjects and two out of 14 subjects showed significant bimodal benefit for CNC word recognition and CNC phoneme recognition in quiet, respectively.

Reiss et al. (2008) tested consonant discrimination on 20 hybrid users. Their subjects had substantially better residual hearing than our bimodal CI subjects. Reiss et al.'s (2008) subjects were implanted with shortelectrode arrays: The most apical electrode (electrode 6) encoded frequencies down to 688 Hz, not covering the entire speech frequency range. Interestingly, the authors' results showed that only about one quarter of the subjects demonstrated substantial improvement with combined acoustic-electric (A+E) conditions compared with A-only or E-only conditions (see Figures 2B and 3A in Reiss et al., 2008) for consonant discrimination. This finding suggests that the reduced benefit observed in our bimodal users is not likely due to overlapping frequency ranges between electric and acoustic stimulation or to the severity of the hearing loss in the acoustic ear in our bimodal CI subjects.

Our modeling results and the estimates of information transmission for various consonant and vowel features provide an insight on the mechanisms that underlie this deficit. The lack of bimodal benefits for consonant identification in CI listeners can be attributed to a combination of factors, including (a) insufficient,misrepresented, or redundant information provided by an individual ear and (b) reduced ability to integrate speech cues across ears. The CI data were best fitwith the PreLI0 model that assumes a minimal adjustment in response from the single-source conditions to the multisource condition. This indicates that CI listeners performed suboptimally compared with their NH counterparts. For consonant identification, all subjects (except for C3) showed an absence of bimodal benefit, with bimodal scores essentially the same as the CI-alone or HA-alone scores-whichever was higher. For example, Subjects C4 and C10 performed similarly with HA- and CI-alone to the LP- and vocoder-alone conditions observed inNH listeners, but they did not obtain the

bimodal benefits that NH listeners did.

Although the PreLI0 model produced a good fit for many of the CI subjects for consonant identification, it slightly underpredicted the combined scores for Subjects C7, C8, and C11. However, none of these subjects showed overall bimodal benefits for consonant identification, which could be attributed to the insufficient or redundant cues provided by the HA ear to improve their performance in the bimodal listening condition. Subjects C8 and C11 achieved overall scores of 15%-16% correct, close to chance-level performance (6.25%). Subject C7 performed better than C8 and C11 with HA alone, but his performance-particularly, the extraction of voicing, stop, and fricative features-was still significantly lower than the LP-alone performance in NH listeners.

Subject C3 showed a bimodal benefit for consonant identification despite the fact that his bimodal performance was best predicted by the PreLI0 model. Unlike other CI listeners, C3 could identify consonants in the HA-alone condition with an overall score of 78% correct, 34 percentage points higher than the LP-alone score in NH listeners, whereas his CI-alone performance was comparable to the NH four-channel vocoder performance. Despite his high level of performance on the HA condition, he only received a bimodal benefit of 4.4 points. His reduced bimodal benefit may be attributed to his suboptimal integration ability to combine speech cues from both ears.

The relationship between model fit and bimodal benefit is more apparent and direct in the vowel identification task. Five of the six CI subjects tested, except for C12, had similar vowel identification performance with HA alone and with CI alone. However, only three subjects (C2, C5, and C8) showed improved overall vowel identification scores. Interestingly, these three subjects also exhibited an ability to integrate speech cues: Their combined scoreswere underpredicted by the PreLI0model.

Cross-Frequency Integration Deficits in HI Listeners

The present study shows a reduced benefit from additional low-frequency speech cues for phoneme identification in bimodal CI listeners. This finding is consistent with the findings of Grant et al. (2007), who reported that HI listeners received less benefit than NH listeners when additional high-frequency cues were added to low-frequency speech in the auditory-alone condition, but their performance significantly improved and achieved a similar level of performance as that of NH listeners when the high-frequency cues were provided visually in the auditory-visual condition. Grant et al. (2007) attributed these patterns of performance to HI listeners' reduced efficiency in integrating auditory speech cues across spectral regions compared withNHlisteners but similar efficiencies in integrating auditory-visual speech cues. In addition to the interplay between extraction and integration of cues, Grant et al. (2007) discussed other explanations that may underlie the reduced benefits of additional high-frequency speech cues in HI listeners, which may also apply to the CI population. These other explanations are briefly discussed in the subsections that follow.

Peripheral interference-masking. Cross-frequencyintegration in the same ear in HI listeners could have been adversely affected by excessive peripheral upward spread ofmasking due to the broadening of auditory filters.However, the masking effect could not explain the reduced integration ability in our bimodal CI subjects because the low-frequency and high-frequency speech cues were presented to separate ears.

Perceptual salience of additional cues. Turner and Henry (2002) reported that HI listeners can benefit from high-frequency speech cues when consonant recognition performance is relatively poor at low signal-to-noise ratios (SNRs). At this poor performance level, the additional high-frequency speech cues may help to decipher the more "difficult" features of speech. In our study, all of our CI subjects (except for C1) achieved greater than 50% consonant identification with CI alone (or with HA alone, for Subject C12). The additional low-frequency cues from the nonimplanted ear in these subjects may be insufficient to decipher the more "difficult" features, such as voicing and place of articulation. To test this hypothesis, future studies could deliver noise in the CI ear in order to decrease the CI-alone performance to below 50%; this would enable researchers to examine whether the addition of low-frequency speech cues could help improve performance. The exception from Subject C1, who achieved only 41% correct with CI alone but did not receive bimodal benefit, poses a challenge to this

explanation.

Perceptual bias. Ross, Saint-Amour, Leavitt, Javitt, and Foxe (2006) reported that auditory-visual integration is most effective for intermediate SNRs. In high or low SNRs, listeners may have a strong bias toward the cues from the dominant modality and ignore cues from the other modality instead of integrating available cues from both modalities. This form of "interference," as Grant et al. (2007) pointed out, would not be accounted for by the PreL model. Our CI listeners may have had a strong perceptual bias toward their CI ear and may have ignored cues from the HA ear because the HA provided weaker cues than the CI. However, evidence from our CI listeners who did not show ear dominance argues against this explanation. Subjects C3 and C4 showed a relatively good consonant identification score in the HA-alone condition, not significantly different than the CI-alone performance. For these two subjects, their reduced bimodal benefit is not likely to be attributed to a perceptual bias toward one ear, although it is still possible that the cues from one ear are ignored because they are redundant, as in the consonant stimuli. For vowel identification, however, half of the CI subjects showed bimodal benefit, suggesting that they did not ignore cues from the less dominant ear when the ear provided complementary cues.

Age effects and internal noise. Although we did not investigate age effects in this study, we made an effort to recruit CI subjects from different age groups, ranging from 15 to 69 years old. A study by Souza and Boike (2006) showed that age impaired listeners' ability to integrate temporal envelope cues across frequency bands for speech recognition. Seven of 12 CI subjects who were tested in the consonant identification task were under the age of 30 years-within the age range of the NH listeners. The differences in the combined benefit between the two groups cannot be accounted for by age. However, all of the younger subjects and some of the older subjects (e.g., C8 and C12) in our study had an onset of hearing loss in at least one ear at a very young age (<5 years). Although all subjects communicated orally prior to implantation and have developed essentially normal language and reading skills, it is possible that the degraded speech they received since childhood may have affected their development of a normal internal representation of the phonemes compared with their NH counterparts, which in turn might impair their ability to integrate speech cues and to identify stimuli in the combined case. The imperfections of the internal representation of the stimulus due to the excess sensory noise and memory noise (Sagi,Meyer,Kaiser, Teoh,&Svirsky, 2010) in the singlesource and/or combined-source case can also occur in postlingually deafened adults, especially after long-duration hearing loss. This form of deficit would also be viewed as suboptimal integration across frequencies and modalities. Future investigation on response error patterns to individual stimuli and detailed comparisons between the perceptual and stimulus space may provide insight into the underlying cause for the reduced bimodal benefits in CI listeners. Additionally, investigations with nonspeech stimuli and/or with different tasks may further reveal the limiting factors for cross-frequency integration in CI listeners.

Deficits in the cross-frequency processing of temporal speech cues. As suggested by Grant et al. (2007), the reduced integration efficiency for HI listeners may not be simply the product of degraded extraction or integration of cues across frequency bands but instead may be a true deficit in dealing with temporal speech cues such as those reported in Healy and Bacon (2002). Healy and Bacon presented two speech-modulated tones at 750 Hz and 3000Hz toNHand HI listeners. In one condition, the low-frequency band led or lagged the high-frequency band by 12.5-100 ms. The authors found that NH listeners could tolerate small disruptions in cross-frequency timing (i.e., 12.5ms), but performance decreased as the crossfrequency asynchrony increased. However, HI listeners' performance dropped more precipitously than that of their NH counterparts. For consonants, cross-frequency speech cues may not be presented concurrently-for example, stop voicing relies heavily on voice onset time (VOT) cues (VOT is the time interval between burst and the onset of voicing). The reduced bimodal benefit in our CI listeners may be due to their difficulty in comparing temporal speech cues across frequencies. Their ability to integrate speech cues across ears and across frequency bands could also be hindered by the processing delays between their HA and CI as well as differences in processing time

between frequency channels within a single device.

Although the deficit in spectrotemporal processing may seem a likely explanation for the integration deficits in consonant identification in CI listeners, it is still unclear how this can account for CI users' reduced bimodal benefit in vowel identification.Unlike the dynamic properties of consonants, spectral cues for vowel recognition are relatively static. In addition to durational cues (which we did not control for in this study), the identification of vowels was primarily based on the steady concurrent cues for F1 andF2 and does not require integration of cross-frequency temporal speech cues. Therefore, the lack of bimodal benefits in vowel identification may reflect a deficit in cross-frequency integration in some of our CI subjects.

In addition to the deficit in processing temporal cues across frequencies, bimodal CI users may also encounter a problem of incompatibility of the two devices, given that one ear receives acoustic stimulation and the other ear receives electric stimulation. Although all of our CI subjects reported fused auditory images and enjoyed the sound quality better when using both devices, we cannot exclude the possibility that differences in stimulation modes (acoustic vs. electric) and sound quality may also pose difficulties for integration and may create potential interference across ears.

Future Directions

The present study does not suggest that CI users do not receive bimodal or hybrid benefits. It has been well documented that bimodal and hybrid users can achieve better word and sentence recognition (e.g., Dorman et al., 2008; Gifford, Dorman,McKarns, &Spahr, 2007; Kong et al., 2005; Mok et al., 2006, 2009; Reiss et al., 2008; Turner et al., 2004; Zhang et al., 2010). For word and sentence recognition, listeners could be better able to use phonotactic, prosodic, and contextual cues when low frequencies are presented (Brown &Bacon, 2009b; Spitzer, Liss, Spahr, Dorman, &Lansford, 2009; Zhang et al., 2010).Arecent report by Zhang et al. (2010) argues that bimodal benefit for word recognition in quiet can be accounted for entirely due to the presence of fundamental frequency cues alone and that the benefit was not significantly different between conditions in which the nonimplanted ear received only very low-frequency (<125 Hz) versus wide-band speech. Also, it has been suggested that the addition of low-frequency cues can aid listeners in glimpsing the target sentence during the spectral and/or temporal dips of the masker (Brown &Bacon, 2009a; Kong &Carlyon, 2007; Li &Loizou, 2008; Zhang et al., 2010).

The lack of improvement in consonant identification in our CI listeners should not discourage the use of bimodal hearing. Most of our CI subjects exhibited severe to profound hearing loss at the low frequencies-a greater loss than that experienced by some of the CI candidates under the currentFDA guidelines for cochlear implantation. It is possible that bimodal users receive more benefits for phoneme recognition if they have more residual hearing in the nonimplanted ear. Also, our results clearly showed the benefits of using F1 cues from the HA to improve vowel identification in at least some CI listeners. F1 transitions also provide cues for consonant recognition, and the use of these cues has not been fully investigated. In addition, there is evidence in our study suggesting that listeners who have reduced integration ability could still benefit from bimodal stimulation if they receive useful cues from the HA (e.g., Subject C3). Future research could look into ways of improving HA performance in order to deliver more useful speech cues.

Conclusions

We developed the following conclusions as a result of this study.

1. The PreL model of integration is capable of predicting combined-band performance with speech signals that have undergone different signal processing (LP filtering and channel vocoding). Results of model fits for NH listeners for consonant and vowel identification were consistent with those reported in Ronan et al. (2004).
2. When tested with their everyday program/map, bimodal CI listeners received largely redundant information between the two devices for consonants. Both HA and CI provided greater voicing and manner-ofarticulation information but less place-of-articulation information. However, information received between HA and CI was somewhat complementary for vowels, with HA providing mostly F1 information and CI providing more F2

information.

3. Although NH listeners showed significant improvement in a combined LP+vocoder condition for both consonant and vowel identification, the majority of CI listeners did not show bimodal benefits compared with the performance in the better ear for consonant identification, and only half of theCI listeners showed bimodal benefits for vowel identification.

4. Predictions from the PreL model were different between NH and CI groups. NH consonant and vowel identification performance was best fit with the PreLIH assumption, in which the response centers in the multisource case were located halfway between the response centers in the single-source case and multisource stimulus centers. However, the majority of the CI data was best fit with the PreLI0 assumption, in which the response centers in themultisource case were located at the same locations they had in the single-source conditions. The differences in modeling results between NH and CI listeners suggest that CI listeners may have reduced integration ability.

5. The lack of bimodal benefits for phoneme identification in CI listeners can be attributed to a combination of factors, including the insufficient or redundant information provided by an individual ear and/or reduced ability to integrate speech cues across ears.

Acknowledgments

This work was supported by the National Organization for Hearing Research Foundation (Principal Investigator [PI]: Ying-Yee Kong) and National Institute on Deafness and Other Communication Disorders Grants R03 DC009684-01 (PI: Ying-Yee Kong) and R01 DC007152-02 (PI: Louis D. Braida). We are grateful to all subjects for their participation in these experiments. We would like to thank Ken Grant and Joshua Bernstein for their helpful comments and suggestions. We also thank Qian-Jie Fu for allowing us to use his MATLAB programs for performing information transmission analysis.

Appendix

Appendix (p. 1 of 2). Preliminary study: Model predictions for nonoverlapping frequency speech cues in normal-hearing (NH) listeners.

Method

Twelve NH subjects (10 females, 2 males), 19-46 years of age (M = 24 years), participated in the study. Nine of them participated in the consonant identification experiment. Seven subjects participated in the vowel identification task. Four of these seven subjects also participated in the consonant identification task.

Two sets of speech stimuli (consonants and vowels) identical to those in Experiment 1 were used. These stimuli were subjected to low-pass (LP) filtering or channel-vocoding processing. The only difference in processing parameters between this preliminary study and Experiment 1 was that the channel-vocoding processing preserved only highfrequency cues (> 900 Hz); thus, there was no (or very minimal) overlapping in frequencies between the LP and vocoder speech. In this vocoder system, speech signal in a frequency range from 900 Hz to 6000 Hz was band-pass filtered into two, four, or six logarithmic frequency bands (corresponding to the two-channel, four-channel, and six-channel vocoders).

Experimental procedures were the same as those used in Experiment 1. Because there were three vocoder conditions (six-channel vocoder, four-channel vocoder, and two-channel vocoder), there were a total of seven testing conditions (one LP-alone, three vocoder-alone, and three LP+vocoder). Each subject was tested with the six-channel vocoder first, followed by the four-channel vocoder, and then the two-channel vocoder. The order of presentation of the listening conditions (LP-alone, vocoder-alone, LP+vocoder) was counterbalanced across subjects.

Model Predictions

Integration ability across frequencies was evaluated using the PreLI0, PreLI1, and PreLIH integration models that differ in terms of the location of the response centers in the multisource condition described in Ronan et al. (2004). Predictions were made separately for each subject, condition, and task. They were computed by first fitting the vocoderalone and LP-alone matrices in D = 3 dimensions and then predicting the scores for the combined condition from a 6-D model. Figure A1 shows the predicted versus observed combined-source consonant (upper panel) and vowel identification (lower panel) scores for each response center location (triangles: PreLI0; squares: PreLI1; circles: PreLIH). On average, PreLI0 underpredicted the combined performance by about 5 percentage points for consonant identification and 9 percentage points for vowel identification. PreLIH overpredicted the combined performance by an average of 4 percentage points for consonant identification and 3 percentage points for vowel identification. Compared to PreLIH, PreLI1

overpredicted the combined performance to a greater extent with an average of 7 percentage points for consonant identification and 4 percentage points for vowel identification. The root-meansquare- error (RMSE) of the fit was greater for PreLI0 (consonant: 6; vowel: 10) than for PreLIH (consonant: 5; vowel: 4). In general, this pattern of results is similar to those reported in Ronan et al. (2004) for cross-frequency integration for consonant identification in NH listeners, which also showed that PreLI0 consistently underestimated the multiband scores and that PreLIH provided better predictions for cross-frequency consonant identification compared to PreLI1. The consistent pattern of results from the model fits between Ronan et al. (2004) and this preliminary study suggests that the PreL model of integration is capable of predicting combined-band performance when speech signals from different frequency regions undergo different signal processing (LP filtering and channel vocoding).

Abstract: The purpose of this study was to investigate musical timbre perception in cochlear-implant (CI) listeners using a multidimensional scaling technique to derive a timbre space. Sixteen stimuli that synthesized western musical instruments were used (McAdams, Winsberg, Donnadieu, De Soete, &Krimphoff, 1995). Eight CI listeners and 15 normal-hearing (NH) listeners participated. Each listener made judgments of dissimilarity between stimulus pairs. Acoustical analyses that characterized the temporal and spectral characteristics of each stimulus were performed to examine the psychophysical nature of each perceptual dimension. For NH listeners, the timbre space was best represented in three dimensions, one correlated with the temporal envelope (log-attack time) of the stimuli, one correlated with the spectral envelope (spectral centroid), and one correlated with the spectral fine structure (spectral irregularity) of the stimuli. The timbre space from CI listeners, however, was best represented by two dimensions, one correlated with temporal envelope features and the other weakly correlated with spectral envelope features of the stimuli. Temporal envelope was a dominant cue for timbre perception in CI listeners. Compared to NH listeners, CI listeners showed reduced reliance on both spectral envelope and spectral fine structure cues for timbre perception.

Purpose: The purpose of this study was to investigate musical timbre perception in cochlear-implant (CI) listeners using a multidimensional scaling technique to derive a timbre space.

Methods: Sixteen stimuli that synthesized western musical instruments were used (McAdams, Winsberg, Donnadieu, De Soete, &Krimphoff, 1995). Eight CI listeners and 15 normalhearing (NH) listeners participated. Each listener made judgments of dissimilarity between stimulus pairs. Acoustical analyses that characterized the temporal and spectral characteristics of each stimulus were performed to examine the psychophysical nature of each perceptual dimension.

Results: For NH listeners, the timbre space was best represented in three dimensions, one correlated with the

temporal envelope (log-attack time) of the stimuli, one correlated with the spectral envelope (spectral centroid), and one correlated with the spectral fine structure (spectral irregularity) of the stimuli. The timbre space from CI listeners, however, was best represented by two dimensions, one correlated with temporal envelope features and the other weakly correlated with spectral envelope features of the stimuli.
Conclusions: Temporal envelope was a dominant cue for timbre perception in CI listeners. Compared to NH listeners, CI listeners showed reduced reliance on both spectral envelope and spectral fine structure cues for timbre perception.
Key Words: cochlear implant, timbre, music
Cochlear implants (CIs) were originally designed to aid speech recognition for severely hard-of-hearing individuals. Recently implanted CI patients can achieve average sentence recognition scores above 80% correct in quiet (seeWilson&Dorman, 2008).While the temporal-envelope-based coding strategies can support speech recognition, it has been well-documented that these strategies do not provide sufficient information for pitch perception or music appreciation (e.g., Gfeller &Lansing, 1991; Gfeller, Turner, et al., 2002; McDermott, 2004; Kong, Cruz, Jones, &Zeng, 2004; Galvin, Fu, &Nogaki, 2007).
The spectral and temporal properties of music are complex and dynamic. Both categories of cues contribute to the recognition of familiar tunes and the appraisal of the characteristics of music. The aesthetic appreciation of music, however, is multifaceted. It does not solely depend on listeners' ability to follow the melody or pitch contours. Anecdotally, some CI listeners can enjoy music by following the musical rhythms or the lyrics, despite their inability to track many of the melodic and pitchbased characteristics. Kong et al. (2004) systematically studied CI listeners' ability to discriminate tempos, rhythmic patterns, and melodies. They reported that CI listeners were able to follow rhythmic cues for music perception, but their ability to perceivemelodies (pitch cues) was poor, similar to normal-hearing listeners listening to stimuli processed with a one-channel vocoder.
Another important characteristic of musical sounds is timbre. By definition, timbre is the perceptual attribute that distinguishes two sounds that have the same pitch, loudness, and duration (American National Standards Institute, 1973). For musical timbre, this perceptual attribute distinguishes instruments (e.g., guitar vs. piano) playing the same note with the same loudness. One approach of studying timbre perception is to evaluate listeners' ability to discriminate among or recognize musical instruments. This approach has been used extensively to investigate musical timbre perception in CI listeners (e.g., Dorman, Basham, McCandless, &Dove, 1991; Gfeller&Lansing, 1991; Gfeller, Knutson,Woodworth, Witt, &DeBus, 1998; Gfeller,Witt,Woodworth, Mehr, &Knutson, 2002; Gfeller,Witt, Adamek, et al., 2002; Schulz and Kerber, 1994; Leal et al., 2003; McDermott, 2004; Nimmons et al., 2008). In these studies, musical notes or songs played by different instruments (e.g., violin, piano, flute, etc.) were presented to CI listeners and they were asked to identify the instruments either in open set or in closed set. Across studies, CI listeners' performances were generally poorer than normal-hearing (NH) listeners, with average identification scores in the range of about 40-60% correct depending on the number of possible alternatives in a closed set compared to 90-100% correct identification obtained inNHlisteners (Schulz& Kerber, 1994;Gfelleretal., 1998;Gfeller,Witt,Woodworth, et al., 2002; McDermott, 2004; Kang et al., 2009). Another approach to study timbre perception is to evaluate listeners' subjective rating or overall appraisal (i.e., liking) of sounds; this includes subjective characteristics such as pleasantness ornaturalness (e.g., Gfeller&Lansing, 1991; Schulz &Kerber, 1994; Looi, McDermott, McKay, &Hickson, 2007), or sound quality on different perceptual dimensions, such as dull/brilliant, compact/scattered, and full/empty (Gfeller,Witt,Woodworth, et al., 2002).Results from these studies showed that, in general, CI listeners rated the sound quality lower than NH listeners (Schulz &Kerber, 1994; Gfeller &Lansing, 1991; Gfeller et al., 1998; 2000; Gfeller,Witt,Woodworth, et al., 2002). Gfeller, Witt,Woodworth, et al. (2002) reported that CI listeners rated string instruments and instruments played in the higher-frequency range as more scattered, less full, and duller when compared with NH listeners' ratings.
The present study takes another approach to investigate timbre perception in CI listeners (i.e., exploring the

timbre space). The timbre space for NH listeners has been studied extensively (e.g., McAdams et al., 1995; Marozeau, de Cheveign, McAdams, &Winsberg, 2003; Caclin, McAdams, Smith, &Winsberg, 2005). However, it has not been thoroughly examined in listeners with significant auditory impairments. In this approach, we aim to (a) derive amultidimensionalmusical timbre space for CI listeners to compare with the timbre space for NH listeners, and (b) determine the psychophysical nature of the dimensions in the CI timbre space on the basis of the acoustic parameters (temporal and spectral features of the musical instruments) described in previous studies (Krimphoff, McAdams, &Winsberg, 1994; McAdams et al., 1995; Marozeau et al., 2003; Calcin et al., 2005; Peeters, 2004). Because timbre is a multidimensional perceptual attribute, the perception of musical timbre can be represented in a multidimensional Euclidean space using a Multidimensional Scaling (MDS) technique, such that the distances among the stimuli reflect their relative dissimilarities. These perceptual dimensions are often described by terms like brightness, roughness, nasality, naturalness, or impulsiveness. Recent studies have tried to better define timbre by varying different physical parameters of acoustic signals and examining changes in perceived timbre (McAdams et al., 1995; Marozeau et al., 2003; Caclin et al., 2005,Marozeau&deCheveigne, 2007). McAdams et al. (1995) tested a large group of NH listeners (n = 98) with 18 digitally synthesized instruments. The goal of their study was to investigate the physical correlates of the most salient dimensions of timbre. Listeners were asked to make dissimilarity ratings between stimulus pairs. This study indicated that the NHtimbre space can be represented by three dimensions (3D), with each dimension associated with an acoustic feature. The first timbre dimension was highly correlated with the log-attack time of the stimuli and the second dimension was highly correlated with the spectral centroid (i.e., the spectral center of gravity) of the stimuli. The third dimension, however, was only weakly correlated with spectral flux (i.e., the fluctuation of the spectrumover time). Amore recent study by the same group of researchers (Caclin et al., 2005) investigated the psychophysical nature of timbre dimensions by varying individual acoustic properties (i.e., log-attack time, spectral centroid, and spectral flux or spectral irregularity) of harmonic complexes independently. They concluded that when attack time, spectral centroid, and spectral flux were manipulated independently in the stimuli set, the NHtimbre spacewas best fit with a two-dimensional (2D) model. While spectral flux alone contributes to timbre perception, it was not a robust cue for NH listeners to perceive differences in timbre when all three cues were present in the stimuli set. On the other hand, when attack time, spectral centroid, and spectral irregularity (differences in amplitude between adjacent harmonics) were manipulated independently in the stimulus set, the NH timbre space was best fit with a 3D model with one dimension significantly correlated with the attack time, one dimension correlated with the spectral centroid, and one dimension correlated with the spectral irregularity. Based on these results, timbre can be described as a characteristic or quality of sound that depends on both temporal and spectral aspects of sound, both independently and interdependently.

While the relative contribution of different spectral and temporal acoustic features to musical timbre perception in NH listeners is still not fully understood, it has been generally agreed upon that the temporal envelope (e.g., attack time) and spectral envelope (e.g., spectral centroid) are the dominant cues for timbre perception. Previous research has examined CI listeners' ability to discriminate (i.e., measuring just-noticeable difference) independent temporal and spectral acoustic features (attack time and spectral centroid) of the stimuli that contribute to timbre perception and found that CI listeners performed similarly to NH controls (Pressnitzer, Bestel, &Fraysse, 2005). In the present study, we replicated the experimental procedure performed by McAdams et al. (1995) to investigate the relative contribution of temporal and spectral cues to the perception of musical timbre in CI listeners. To our knowledge, our study is the first to derive timbre space in CI listeners. Based on previous findings on the ability of CI listeners to perceive temporal and spectral cues formusic perception (seeMcDermott, 2004; Won, Drennan, Kang, and Rubinstein, 2010 for review), we hypothesized that CI listeners are able to use temporal cues to perceive musical timbre, but their ability to use spectral cues is reduced; thus the timbre space in CI listeners should be different than that obtained from NH listeners.

Method

Listeners

Fifteen NH listeners (4 males, 11 females), ages 19 to 32 years served as a control group. All listeners had hearing thresholds no greater than 20 dBHLfrom 250 to 8000 Hz bilaterally. One listener had extensive musical training for over 15 years, one received some training learning the piano as a child, and the remaining listeners did not have any formal musical training.

Eight CI listeners (C1-C8, 5 males, 3 females), ages 15 to 63 years (mean = 36.75 years) participated in the study. Table 1 shows detailed demographic information for each listener, including age, onset of hearing loss, etiology of hearing loss, duration of severe-to-profound hearing loss prior to implantation, the CI processor used, and phoneme(consonant and vowel) identification scores. Half of the listeners were under the age of 30, close to the age range of the NH listeners. The remaining listeners were in the age range from 46 to 63 years old. All listeners, except for C1, were prelingually or perilingually hardof- hearing bilaterally. For these listeners, hearing loss was progressive from mild to severe-to-profound in three listeners (C4, C5, C8). The other four listeners had a severe hearing loss at birth or at a very young age (C2, C3, C6, C7). Three listeners (C1, C5, C6) used a hearing aid (HA) in the nonimplanted ear. Subject C8 was implanted in both ears at the time of the study, and the ear that received the first implant, which also yielded better speech recognition, was tested in this study. This listener was implanted with a five-channel Ineraid device and used a Geneva processor in the ear that was tested in this experiment. None of the CI listeners received formal musical training.

Phoneme recognition was evaluated on each CI listener as part of our overall assessment routines. Due to time constraints, listener C1 was only tested with consonant recognition and listener C3 was only tested with vowel recognition. Consonant recognition consisted of 16 consonants ... recorded by threemale and three female talkers (Shannon, Jensvold, Padilla, Robert, &Wang, 1999) in the /aCa/ context.Vowel recognition consisted of ninemonophthongs ... in the /hVd/ context recorded from three male and three female talkers in our laboratory. Nine blocks of testing were performed on each listener for each task, yielding a total of 54 trials per stimulus per task per listener, except for listener C1 who was only tested with a total of 42 trials per stimulus per task, due to time constraints. In our subject group, consonant and vowel identification scores ranged from39-92%(M= 60%) and 60-90% (M = 76%), respectively (see Table 1). This range of performance indicates that our sample represents a typical CI population (see Wilson &Dorman, 2008).

Stimuli

The stimuli were the digitally synthesized musical instruments used in McAdams et al. (1995), which were developed by Wessel, Bristow, and Settel (1987). These sounds were synthesized on a Yamaha TX802 FM Tone Generator. In order to reduce the session duration, only 16 out of the original 18 stimuli were selected. These 16 stimuli were bassoon (bsn), English horn (ehn), guitar (gtr), guitarnet (gtn), harpsichord (hcd), French horn (hrn), harp (hrp), obochord (obc), piano (pno), striano (sno), bowed string (stg), trombone (tbn), trumpar (tpr), trumpet (tpt), vibrone (vbn), and vibraphone (vbs). Eleven of the instruments were designed to imitate traditional western instruments (e.g., piano, guitar) and five were hybrids of two instruments (e.g., vibrone) to contain the perceptual characteristics of both instruments (see Table 2 and descriptions in McAdams et al., 1995). The hybrid instruments were designed by McAdams et al. (1995) to investigate if an instrument that is physically a mixture of two other instruments will appear in the perceptual space located somewhere between the two instruments of which it is composed. All stimuli had the same fundamental frequency (F0) 311 Hz (E-flat 4). The durations of these sounds ranged from 495 ms to 1096 ms. According to McAdams et al. (1995), these physical differences in duration across stimuli were required to produce similar perceptual duration for NH listeners. The stimuli were scaled to have equal maximum level. This specific set of stimuli was selected for the present study because it was tested extensively with NH listeners. In order to validate our derived timbre space, it was important to use the same stimuli and methods to facilitate comparisons with previous studies.

Procedure

All listeners were tested in a double-walled soundattenuating booth (8¶6µ ×8¶6µ). Stimuli were presented from a loudspeaker (M-Audio Studiophile BX8a Deluxe) one meter in front of the listeners. This loudspeaker has flat frequency response (±2 dB) from 40 to 22000 Hz. First, each listener was asked to adjust the level of individual sounds at their most comfortable listening level for equal loudness. During the loudness-balancing procedure, the bassoon stimulus was chosen as the reference sound and the listeners were asked to adjust the level of this sound to reach their most comfortable listening level. Once the level of this reference sound was determined, the listeners then adjusted the level of the rest of the stimuli to match the loudness of this reference sound. After the adjustment for each individual stimulus, the listeners played the sounds one at a time and made further adjustments as necessary if any of the stimuli sounded noticeably louder or softer than the rest. Thus, the presentational levels were different for different stimuli and for different listeners. Cochlear-implant listeners used their own normal CI settings during the entire experiment. Those who wore a hearing aid in the nonimplanted ear (C1, C5, C6) or those who had two CIs (C8) were instructed to turn off their HA but leave their ear-mold in place in that ear, or to turn off the nontest implant. A foam earplug was inserted in the implanted ear(s) or in the nonimplanted ear for non-HA users during testing to prevent any potential acoustic stimulation in case residual hearing was preserved.

Prior to the experiment, each listener was instructed that the goal of the study was to estimate the similarity of sound quality between sounds. They were told that each sound used in the experimentwas the same musical note and that the loudness should be roughly the same across sounds given that they already adjusted the level of each sound to produce equal loudness prior to the experiment.

For the experiment, listeners were first familiarized with the 16 stimuli by listening to each stimulus one at a time as many times as they wanted. Subsequently, all possible pairs of the 16 stimuli (16 ×16 = 256 pairs) were presented in random order. Subjects were instructed to judge the dissimilarity of the two sounds in each pair by adjusting the sliding bar on a computer screen. The sliding bar was marked with numbers from 1 to 10 in steps of 1, and with labels most similar next to the number 1 and most different next to the number 10. Subjects were encouraged to use the whole range of the scale. For each trial, listeners could play the pair as many times as they wanted before making a dissimilarity rating. Each listener was allowed to take a break at any time during the experiment. Before data collection, each listener received a training session that consisted of 20 randomly selected pairs to ensure that they understood the task and to practice making the dissimilarity rating. Each NH listener performed the experiment once and each CI listener performed the experiment two or three times depending on the availability of the listener. Overall, each pair of stimuli was rated 30 times by theNHgroup and 42 times by the CI group.

Acoustical Analyses

One of the goals of this study was to investigate the psychophysical nature of the dimensions of the CI timbre space. To achieve this goal, we performed acoustical analyses on the 16 stimuli used in this study, based on the descriptions in Krumhansl (1989), Krimphoff et al. (1994), McAdams et al. (1995), and Peeters, McAdams, &Herrera (2000) for harmonic signals, and mathematical formulae (see Appendix) provided by Peeters (2004). These analyses were performed to examine the following temporal and spectral characteristics of the stimuli, which have been shown in various reports (Krimphoff et al., 1994; McAdams et al., 1995; Marozeau et al., 2003) to contribute to the perception of timbre using the stimuli employed in this study:

* Log-Attack Time: Defined as the logarithm of the duration from the time at which the amplitude of the stimulus reaches its threshold (i.e., 10% of its maximum value in our calculation) to the time at which the amplitude reaches its maximum.
* Spectral Centroid: defined as the spectral center of gravity, which is calculated as the amplitude weighted mean of the harmonic peaks averaged over the sound duration.
* Spectral Spread: defined as the spread of the spectrum around its means, which is calculated as the amplitude weighted standard deviation of the harmonic peaks averaged over the sound duration.

* Spectral Flux: defined as the amount of variation of spectrum over time, which is calculated as the normalized cross-correlation between the amplitude spectra of two successive time frames.
* Spectral Irregularity: defined as the deviation of the amplitude harmonic peaks from a global spectral envelope derived from a running mean of the amplitude of three adjacent harmonics averaged over the sound duration.

In addition, the temporal feature, impulsiveness, and the spectral features, spectral centroid and spectral spread of the stimuli were computed using a perceptual-based model described by Marozeau et al. (2003). In this model, impulsiveness is calculated as one minus the ratio that is defined as the duration during which the smoothed power (instantaneous power smoothed by convolution with a 3.2-ms square window) is above 50% of its maximumvalue divided by the duration forwhich the smoothed power is above 10%. Spectral centroid and spectral spread are defined the same as above, but this computation took into account middle-ear filtering and the logarithmic band conversion to the spectrum, bymimicking the perceptual critical bands. The details of these computations can be found in Marozeau et al. (2003).

While log-attack time and impulsiveness represent the temporal characteristics (temporal envelope in particular) of the stimuli, the rest represent the spectral characteristics. The spectral information can be further divided into two categories: spectral envelope and spectral fine structure. The spectral centroid and spectral spread categorize the overall spectral shape (i.e., spectral envelope) of the stimuli averaged over time. On the other hand, the spectral irregularity (spectral fine structure) describes the relationship between individual harmonics and the global spectral envelope. Thus, in order to use this cue to perceive timbre, listeners will need to have the ability to encode the variations of amplitude between neighboring harmonics. The last acoustic parameter, spectral flux, categorizes the change of the overall spectrum over time and can be categorized as a spectrotemporal parameter.

Results

NH Timbre Space and Acoustic Correlates

The dissimilarity matrices from 15 NH listeners were analyzed using a weighted Euclidean model - Individual Differences MDS (INDSCAL) analysis (Carroll &Chang, 1970) in SPSS version 17.0. In this model, the salience of each resulting dimension in the perceptual map is weighted differently for each listener. The dissimilarity matrices were first examined in different numbers of dimensions for interpretation. The stress (a goodness-of-fit measure for MDS analysis) was calculated as a function of number of dimensions, from two to five. The goodness of fit can be evaluated by a measure of stress, which will decrease with the number of dimensions. An optimal fit is usually indicated by the presence of a kneepoint in the stress function. Our results show a decrease in stress as the number of dimensions increased, but no clear kneepoint was identified. Subsequently, we fit the data with a 3D solution based on previous experiments with the samestimuli (Krumhansl, 1989;McAdams et al., 1995). The 3D timbre perceptual map is shown in Figure 1. This map displays the relatively dissimilarity distance among the 16 stimuli used in the experiment. The overall weight for each dimension was derived from the INDSCAL analysis. Dim 1 received the greatest weight (.29) followed, by Dim 2 (.12) and Dim 3 (.10), which received weights of about one-half and one-third of that of Dim 1, respectively. These weights indicate the relative saliency of each perceptual dimension to the perception of timbre-the higher the weight, the more salient the perceptual dimension.

Results from the acoustical analyses on each of the temporal and spectral acoustic parameters described above were used to correlate with the coordinates of the 16 stimuli for each of the MDS dimensions for the 3D solutions provided by the INDSCAL analysis (Table 3). This was done to determine the psychophysical nature of each dimension. Due to the fact that some of the acoustical parameters are significantly correlated with each other in our stimuli (e.g., spectral centroid and spectral spread are significantly correlated, $r = .58$, $p = .02$) and the number of correlations examined, an a level of .01 was selected for all correlational analyses between perceptual dimensions and acoustic parameters. This value helps to reduce the chances of overinterpretation of weak correlations when the selected acoustic parameters merely covary with the true underlying parameters

(e.g., see discussion in Caclin et al., 2005).

Dimension 1 (Dim 1) was found significantly correlated with log-attack time (temporal envelope cue; r = .79, p ≤.0005); Dim 2 was significantly correlated with spectral centroid (spectral envelope cue) (r = .82, p ≤.0001); and Dim 3 was significantly correlated with spectral irregularity (spectral fine structure) (r = .60, p ≤.01). Spectral flux was not correlated (p >.05) with any of the dimensions. It isworth noting that the spectral spreadwas also significantly correlated with Dim 1 (r = -.64, p ≤.01), which seems surprising given that Dim 1 was strongly correlated with the temporal characteristics of the stimuli (log-attack time) and that it has been repeatedly reported in the literature that one of the dimensions in a 3D timbre space is a temporal dimension. Careful examination of the stimuli and the acoustic parameters revealed that spectral spread covaried to some extent with the temporal envelope of the stimuli, such as the impulsiveness of the sound (r = -.55, p ≤.05) and that the impulsiveness feature was highly correlated with Dim 1 (r = .83, p ≤.001). Other spectral parameters- spectral centroid, spectral irregularity, and spectral flux- were not correlated with the temporal envelope of the stimuli nor were they correlated with each other.

Patterns of results remained the samewhen the temporal and spectral acoustic parameters were computed with the perceptual-based model described by Marozeau et al. (2003). Figure 2 displays the relationships between the physical dimension and the perceptual timbre dimension that best represents the acoustic parameter. The solid line on some of the panels represents a regression line indicating significant correlation between the acoustic parameter and the perceptual dimension.

CI Timbre Space and Acoustic Correlates

MDS analyses were performed for CI group data using INDSCAL analysis and for individual listeners using the traditional MDSCAL procedure, implemented in MATLAB (R2009a) according to the scaling-by-majorizinga-complicated-function (SMACOF) algorithm (Borg &Groenen, 1997). For individual listeners, an average dissimilarity matrix was created by averaging the matrices from different runs (2-3 runs depending on the listener) and by folding the matrix (e.g., the pair gtn-tpt was averaged with the pair tpt-gtn) resulting in four to six estimations per pair of instruments.MDSCAL analysis was then performed on the averaged, folded matrix for each listener.

For the CI group data, the INDSCAL analysis showed no clear kneepoint in the stress function relative to the number of dimensions. Thus, a CI timbre space map was derived using a 3D solution. Similar to NH data, the overall weight was the highest for Dim 1 (.35), followed by Dim 2 (.12) and Dim 3 (.11), suggesting that similar to their NH counterparts, CI listeners relied greatly on the temporal envelope cues to perceive timbre.Unlike the NH results, in which each of the three MDS dimensions associated with one or two acoustic features, Dim 2 and Dim 3 in the CI 3D space did not significantly correlate with any of the temporal or spectral parameters under investigation. The temporal envelope feature log-attack time was strongly correlated withDim 1 (r = .88, p≤.0001; see Table 4). The spectral envelope and fine structure features, however, did not significantly correlate with any of the perceptual dimensions. These patterns of results differed considerably from those obtained in NH listeners, which suggests that the spectral cues are less salient or reliable cues to CI listeners than to NH listeners for timbre perception. In order to further investigate the psychophysical relations, the CI group data was fit with a 2D solution. In this 2D solution: (1) Dim 1 was strongly and significantly correlated (r = .88, p ≤.001) with logattack time; (2) Dim 2 was significantly correlated with spectral centroid (r = .62, p ≤.01). The overall weight for Dim 1 (.40) was considerably higher than that for Dim 2 (.17), suggesting that perceptual salience was higher for temporal envelope than for spectral envelope cues for CI listeners. (See Table 5 for perceptual weights for individual listeners.) It is noted that the correlation between spectral centroid and Dim 2 improved from .50 in the 3D solution to .62 in the 2D solution, whereas the strength of correlation between log-attack time and Dim 1 remained unchanged in the 2D solution. This shows that the fit of the model to the relevant acoustic parameters was enhanced by reducing the number of dimensions to 2D.

We then performed MDS analysis on individual CI data, using the MDSCAL model. Half of the listeners (C2, C4,

C6,C8) showed a clear kneepoint for 2 dimensions and the other half (C1, C3, C5, C7) did not show a clear kneepoint. Preliminary analyses using a 3D solution for the four CI listeners who did not exhibit a clear kneepoint, showed a lack of psychophysical correlates with the third dimension, and their patterns of results were similar to the CI group data. We subsequently fit the data with a 2D model for all CI listeners. In the 2D solution after procrustean rotation toward the overall INDSCAL solution for the CI group data, one of the dimensions significantly ($p \leq .01$) correlatedwith log-attack time for almost all subjects, except for C7 (see Table 6 for individual data). The other dimensionwas significantly correlated with the spectral envelope parameters (spectral centroid or spectral spread) in only three listeners (C3: Dim 2 and spectral centroid; C6: Dim 2 and spectral spread; C7: Dim 1 and spectral spread). The significant correlation between Dim 1 and spectral spread for listener C7 and lack of correlation with any temporal parameters (e.g., log-attack time and impulsiveness), suggests that Dim 1 is a spectral dimension for this listener. Dim 2 for listener C6, which was significantly correlated with spectral spread, was also significantly correlated with impulsiveness ($r = .69$, $p \leq .005$). Given that spectral spread and impulsiveness covary, Dim 2 could be also a temporal dimension for C6.Twolisteners (C1,C2) showed significant correlation between Dim 2 and spectral irregularity. The remaining three listeners (C4, C5, and C8) did not show any significant correlation betweenDim2 and any of the spectral parameters, suggesting that these three listeners relied mainly on temporal envelope cues to perceive timbre differences.
In summary, CI data were best described in a 2D perceptual model with one dimension representing the temporal envelope characteristic and the other dimension representing the spectral characteristic of the stimuli. With only one exception (C7), all CI listeners showed significant correlation between one dimension and the log-attack time. Only half of the listeners showed significant correlation between the one dimension and spectral parameters. It is noted that while the strength of correlation with log-attack time was strong and comparable between NH and CI listeners, correlation with spectral envelope was considerably lower in CI group data ($r = .62$) compared to NH listeners ($r = .82$), suggesting that spectral envelope cues were less reliable or salient in the CI group.
Figure 3 left panels show the 2D space for the CI group data (see Figure 3a) and the acoustic correlates to each dimension (see Figures 3b-3e). It is apparent that the correlation between Dim 1 and log-attack time is considerably higher than the correlation between Dim 2 and spectral centroid. The right panels show the 2D space (see Figure 3f) and the acoustic correlates (or lack of) for each perceptual dimension (see Figures 3g-3j) for one listener to illustrate that some CI listeners (e.g., C8 in Figure 3, right panels) relied primarily on the temporal envelope cues to perceive differences in timbre, while others (e.g., the CI group data in Figure 3 left panels) used temporal and spectral envelope cues for timbre perception. It is clear in this figure that the perceptual distance between stimuli inDim 2 was very small for listener C8 compared to the NH and CI group space.

Discussion

NH Timbre Space and Acoustic Correlates

Our results show that NH listeners used temporal envelope, spectral envelope, and spectral fine structure cues to perceive differences in musical timbre, consistent with previous findings (Krimphoff et al., 1994; Caclin et al., 2005). The third dimension, however, did not correlate with the acoustic parameter spectral flux, which was reported byMcAdamset al. (1995). It should be noted that although spectral flux was significantly correlated with Dim 3 in McAdams et al., the correlation was weak ($r = .54$). OurNHDim 3 was significantly correlated with spectral irregularity, consistent with results reported by Krimphoff et al. (1994). This difference between our results and McAdams et al.'s results could be due to a number of factors, including: (a) the use of a loudspeaker in this study instead of headphones; (b) the number of stimuli used (16 stimuli in this study as opposed to 18 stimuli in McAdams et al.); and (c) differences in analysis models (INDSCAL in this study and CLASCAL in McAdams et al.). Indeed, the lack of correlation between Dim 3 and spectral flux was also found recently by McAdams and colleagues in Caclin et al. (2005). Caclin et al. found that an MDS 2D solution provided a better

fit to their dissimilarity data and spectral flux was not correlated with any of the perceptual dimensions when attack time, spectral centroid, and spectral flux were the varying parameters in the stimuli set. They concluded that this could be due to the fact that their model of spectral flux is not perceptually relevant, or spectral flux is a less salient parameter than the other two (log-attack time and spectral centroid).

Temporal and Spectral Cues for Timbre Perception in CI Listeners

UnlikeNHresults, CI results were best represented in a 2D timbre space. The reduced number of dimensions for CI listeners could be interpreted in the followingways: (a) the relative significance of temporal and spectral cues to timbre perception is different between NH and CI listeners or (b) CI listeners may not have detected smaller perceptual differences between instruments, particularly in the spectral domain. In general, one of the perceptual dimensions in the CI 2D space can be regarded as a temporal dimension in which this perceptual dimension was highly correlated with the temporal envelope characteristics of the stimuli. The other dimension can be considered a spectral dimension, which was correlated with the spectral envelope characteristics of the stimuli. However, the weak or lack of correlation between spectral centroid/spectral irregularity and the second dimension in the CI group data suggests that the spectral cues were less reliable cues for timbre perception in CI listeners compared with their NH counterparts. Indeed, the patterns of results in the CI group data are supported by the findings from individual CI listeners, where only half of the CI listeners showed significant correlation between a perceptual dimension and spectral envelope and spectral fine structure parameters. The other half of the listeners, on the other hand, relied mainly on temporal envelope cues to perceive differences inmusical timbre.

The contribution of temporal and spectral envelope cues formusical timbre perception has also been reported previously (Gfeller et al., 1998; Gfeller,Witt,Woodworth, et al., 2002;Gfeller,Witt,Adamek, et al., 2002; McDermott, 2004; Pressnitzer et al., 2005).McDermott (2004) showed a confusion matrix from a group of CI listeners tested on a musical instrument identification task. The 16 instruments used in the study were categorized into two groups: nonpercussive single instrument and percussive single instrument. They found that more confusions were made among the instruments within the same category (i.e., percussive or nonpercussive) than between categories. Based on these patterns of confusions, they concluded that temporal envelope cues are salient cues for musical timbre perception. Pressnitzer et al. (2005) created bandpass-filtered harmonic complexes that varied in the attack time and spectral centroid independently to obtain just-noticeable difference (JND) measures from a group of CI listeners. They reported that performance was good for both attack time and spectral centroid discrimination tasks, suggesting that temporal and spectral envelope cues contributed to timbre perception in CI listeners. Unlike Pressnitzer et al.'s study, we derived timbre space and investigated the relative salience of cues for timbre perception for CI listeners. The fact that CI listeners were able to discriminate differences in spectral centroid, as reported in Pressnitzer et al. (2005), did not necessarily imply that the spectral centroid cue is a reliable or salient cue for timbre perception in CI listeners, especially when other cues (e.g., temporal envelope cues) are also available in the stimulus set. Although our findings were consistent with previous reports on musical instrument identification task, it is unclear if the patterns of results in this study can generalize to stimuli that have higher F0s. At higher F0s, the spacing between harmonics is larger, resulting in harmonics encoded in different CI channels that are farther apart compared to stimuli with lower F0s. This would affect the degree of reliability and saliency of spectral cues for timbre and pitch perception in CI listeners. Singh, Kong, and Zeng (2009) found that melody recognition improved when the set of stimuli was in a higher frequency range compared to the lower frequency ranges. In addition, Gfeller, Witt, Woodworth, et al. (2002) reported significant differences in the perception of timbre at different frequency ranges.

Unlike pitch perception, forwhich temporal and spectral envelope cues elicit only nonsalient pitch, temporal and spectral envelope cues are robust for musical timbre perception (McAdams et al., 1995). This difference could explain the relatively good performance (40-60%) in musical instrument identification compared to the close-

tochance- level performance for melody recognition in the CI listeners when the frequency difference between notes was a few semitones (see McDermot, 2004; Kong et al., 2004), due to mis- or under-representation of temporal and/or spectral fine structure cues. The reduced ability of CI listeners to utilize the fine structure cues could be attributed to both biological and device-related factors, including: electrode-to-frequencymismatch, reduced number of neural survivals resulted fromlong-duration of deafness, and the removal of fine structure of the acoustic signals in the current envelope-based speech processing strategies.

Timbre and Speech Perception in Electric Hearing

Based on the fact that the temporal and spectral envelopes contribute considerably to both speech (Shannan, Zeng, Kamath, Wygonski, &Ekelid, 1995) and timbre perception, the relationship in performance between these two measures warrants some discussion. Particularly, in quiet, consonant recognition relies heavily on temporal envelope cues and vowel recognition requires coarse spectral representation. The relationship between speech recognition and timbre perception has been investigated previously. Kang et al. (2009) found a significant correlation between consonant-nucleus-consonant (CNC) word recognition (both in quiet and in noise) andmusical instrument identification scores in a large group of CI listeners (n = 42). Gfeller et al. (1998), on the other hand, showed a lack of association between musical instrument identification scores and speech recognition scores in a group of 28 CI listeners.

In this study, we obtained consonant and vowel recognition scores (see results in Table 1) from each CI listener. Correlational analyses were performed between phoneme recognition scores and the correlation values of log-attack time with Dim 1 (temporal dimension), and correlation values of spectral centroid with Dim 2 (spectral dimension). Similar to the findings reported by Gfeller et al. (1998), we also found no significant correlation ($p > .05$) between phoneme (consonant and vowel) recognition and timbre perception on the temporal or spectral dimension. That is, listeners who achieved high levels of speech recognition (>80%) were not necessarily able to use temporal (e.g., C7) or spectral (e.g., C6) envelope cues to perceive timbre differences. In addition, the lack of correlation between timbre and speech perception in our study was consistent with the absence of relationship between rhythmic pattern recognition, melody recognition, and speech recognition reported previously (e.g., Kong et al., 2004). However, the difference between the findings in Kang et al. (2009), which showed a significant correlation between instrument identification and speech recognition, and the findings in this study could be attributed to (a) the small sample size in our data; and (b) differences in stimuli (both speech and musical) and tasks (subjective distance vs. identification).

Conclusions

The present study was designed to investigate timbre perception ability in CI listeners and to derive musical timbre space from CI listeners. This space was examined for correlations with known acoustic parameters that contribute to musical timbre perception as reported in the literature. Results showed that CI listeners, unlike their NH counterparts, were less able to use spectral cues to distinguish differences in musical timbre. In addition, no reliable relationship was found between phoneme recognition and the salience of temporal and spectral cues for timbre perception in our CI listeners.

Although we have demonstrated that CI listeners can use temporal and spectral envelope cues for timbre perception, it is still unclear how their ability to perceive differences in musical timbre affects their perception of the "pleasantness," "naturalness," "richness," or other perceptual descriptors of sounds. In order to bridge between the present work and these perceptual characteristics, future studies could examine the relationship between timbre space and subjective ratings or appraisal of sound quality.

Acknowledgments

We gratefully acknowledge the support provided by National Institute on Deafness and Other Communication Disorders Grant R03 DC009684-02 to the first author and Northeastern University Provost Faculty Development Research Grant to the first and fourth authors.We are grateful to all listeners for their participation in the experiment. We would like to thank Professor Stephen McAdams for providing the stimuli.

Abstract: In the present review, we focus on how commonalities in the ontogenetic development of the auditory and tactile sensory systems may inform the interplay between these signals in the temporal domain. In particular, we describe the results of behavioral studies that have investigated temporal resolution (in temporal order, synchrony/asynchrony, and simultaneity judgment tasks), as well as temporal numerosity perception, and similarities in the perception of frequency across touch and hearing. The evidence reviewed here highlights features of audiotactile temporal perception that are distinctive from those seen for other pairings of sensory modalities. For instance, audiotactile interactions are characterized in certain tasks (e.g., temporal numerosity judgments) by a more balanced reciprocal influence than are other modality pairings. Moreover, relative spatial position plays a different role in the temporal order and temporal recalibration processes for audiotactile stimulus pairings than for other modality pairings. The effect exerted by both the spatial arrangement of stimuli and attention on temporal order judgments is described. Moreover, a number of audiotactile interactions occurring during sensory-motor synchronization are highlighted. We also look at the audiotactile perception of rhythm and how it may be affected by musical training. The differences emerging from this body of research highlight the need for more extensive investigation into audiotactile temporal interactions. We conclude with a brief overview of some of the key issues deserving of further research in this area. [PUBLICATION ABSTRACT]

The boundaries between hearing and touch: the foundation of an analogy

We continuously interact with environments that provide a large amount of multisensory information to our various senses. Researchers have now convincingly demonstrated that the inputs delivered by the different sensory channels tend to be bound together by the brain (see the section Research on hearing and touch: a multisensory perspective for a fuller discussion of this topic). Unlike the audiovisual and visuotactile sensory pairings, those interactions taking place at both the neuronal and behavioral level between audition and touch have, to date, been explored in far less detail (see Kitagawa &Spence, 2006; Soto-Faraco &Deco, 2009, for reviews of the extant literature). The paucity of research covering this modality pairing is rather surprising when one considers the wide range of everyday situations in which we experience-even though often in subtle and unconscious ways-the interplay between these two senses. Examples include perceiving the "auditory" buzzing and the itchy "tactile" sensation of an insect landing on the back of our neck; reaching for a mobile phone ringing and vibrating in our pocket. What is common to these situations is the exclusive-or, at the very least, predominant-reliance on cues provided by the nonvisual spatial senses. In addition to these anecdotal reports, there is a growing body of empirical evidence demonstrating the existence of important similarities between the senses of hearing and touch (e.g., Soto-Faraco &Deco, 2009).

In his pioneering early work, von Békésy (1955, 1957, 1959) drew a number of parallels between the senses of audition and touch, which turned out to be so close as to lead him to consider the sense of touch as constituting a reliable model for the study of functional features of audition. For instance, von Békésy (1955) noted that audition and vibrotaction are analogous with regard to the level of the encoding mechanisms at their respective receptor surfaces. Indeed, both the basilar membrane of the inner ear and the mechanoreceptors embedded in the skin respond to the same type of physical energy-namely,mechanical pressure having a specific vibratory rate (e.g., either touching the surface of the skin with a vibrating body or stimulating the stapes footplate of the ear determines the propagation of travelling waves; von Békésy, 1959; cf. Nicolson, 2005).

The analogies in the physiological mechanisms (see Corey, 2003; Gillespie &Müller, 2009) underlying vibrotactile and auditory perception are likely rooted in the common origins of these two sensory systems (see Soto-Faraco &Deco, 2009; and von Békésy, 1959, for reviews). From this particular point of view, many pieces of evidence might be informative with regard to the existence of favored links between hearing and touch, in both animals (e.g., Bleckmann, 2008; Peck, 1994; Popper, 2000) and humans (Marks, 1983; von Békésy, 1959). The onset of function within the systems involved in sensory processing occurs in the following order: from the somesthetic and vestibular modalities to the chemosensory (oral and nasal), the auditory, and lastly, the visual modalities (see Gottlieb, 1971; Lickliter, 2000; Lickliter &Bahrick, 2000; see also Lagercrantz &Changeux, 2009; see Fig. 1).

The order in which the modality-specific as well as multisensory neurons in the anterior ectosylvian sulcus emerge also follows a precise time course, from tactile responsive to auditory responsive, and finally, to visually

responsive neurons (Wallace, Carriere, Perrault, Vaughan, &Stein, 2006). Therefore, one cannot rule out the possibility that the line of development of the different sensory systems might not have some effect upon the successive strength, direction, and amount of reciprocal connections between them (e.g., Gregory, 1967; Katsuki, 1965; Lickliter &Bahrick, 2000).

Although the assessment of the nature of the stimulation that takes place during prenatal life, as well as the responsivity of the fetus to such stimulation, is problematic, the human fetus has been shown to respond to simultaneous stimulation in different sensory modalities since very early in development (e.g., Kisilevsky, Muir, &Low, 1992). Interestingly, the responses of the human fetus-as measured by heart rate and body movements-show an increase when stimulation is both vibratory and auditory as compared with when stimulation occurs in just one sensory modality in isolation (cf. Kisilevsky &Muir, 1991). Moreover, since the responsivity to vibroacoustic stimulation follows a specific maturational time line across gestation (Hoh, Park, Cha, &Park, 2009), any perturbation of the pattern of responses elicited by this kind of stimulation is thought to have a relevant diagnostic function during complicated pregnancies (D'Elia, Pighetti, Vanacore, Fabbrocini, &Arpaia, 2005; Morokuma et al., 2004). It is plausible that the presentation of stimuli in close temporal proximity could support the deployment during later development of the favored processing of specific co-occurring crossmodal sensory inputs (see Lecaunet &Schaal, 1996). Moreover, since the human fetus can respond to vibrotactile and acoustic information by the third trimester (Kisilevsky, 1995), whereas visual information is not fully transduced prior to birth, it is likely that crossmodal temporal synchrony is primarily experienced for the pairing of somatosensory and auditory signals (Lewkowicz, 2000).

The evidence emerging from embryology research is related with the commonality of some physical properties which, according to von Békésy (1959), are shared between audition and touch, such as pitch, loudness, volume, roughness, distance, on-and-off effects, and rhythm. For instance, in one experiment, participants were presented with a pair of clicks (one to either ear, separated by a variable time interval). As the time difference was increased from zero, the sound seemed to travel from one side of the participant's head to the other (i.e., with a leftward or rightward direction), and the participants were asked to point to the direction from which the sound seemed to come. In certain conditions, air pulses were presented across the participant's forehead. By adjusting the magnitude and timing of either auditory clicks or spatially coincident air-puffs so that the skin sensations matched the sensations produced by the acoustic clicks as closely as possible, von Békésy (1959) succeeded in demonstrating that observers found it very difficult to phenomenologically discriminate between auditory and tactile stimuli when they appeared to come from the same direction. This result points to the existence of remarkable analogies-at least under certain specific conditions of stimulus presentation- between the two senses, which could also possibly reflect how the signals from these two sensory modalities interact, at both the neural and behavioral levels.

In this review, a multisensory perspective will be adopted in order to provide an overview of those behavioral studies that have investigated interactions between auditory and tactile stimuli. The focus will be on the audiotactile interactions occurring within the temporal domain. Interest in temporal perception, both theoretical (e.g., Crystal, 2009; Droit-Volet &Gil, 2009; Gibbon, 1977; Glicksohn, 2001; Pöppel, 1997; Wittmann, 2009) and experimental (e.g., Grondin, 2010; Mauk &Buonomano, 2004), has been growing rapidly amongst the scientific community in recent years. According to certain authors, the emerging data are now consistent with humans having an amodal representation of time, one that is shared among different sensory modalities (cf. van Wassenhove, 2009). The remarks provided by van Wassenhove, though intriguing, are however currently confined to the auditory and visual modality pairing. In the present review, our aim has been to provide complementary coverage of the crossmodal nature of temporal perception by focusing on the audiotactile stimulus pairing instead.

Research on hearing and touch: a multisensory perspective

The process by which the human nervous system merges the available information into unique perceptual

events is commonly known as multisensory integration (see Calvert, Spence, &Stein, 2004, for a review). Operationally, multisensory integration has been defined at the neuronal level as "a statistically significant difference between the number of impulses evoked by a crossmodal combination of stimuli and the number evoked by the most effective of these stimuli individually" ("multisensory enhancement;" Stein &Stanford, 2008, p. 255). This principle has been derived from a large body of studies conducted on the activity of neurons in the superior colliculus (SC), a midbrain structure involved in orienting behaviors. The specificity of this structure lies in the fact that it receives unisensory inputs from vision, touch, and audition (Rowland &Stein, 2008; see Stein &Meredith, 1993, for a review). On the basis of the available neurophysiological evidence, it is known that the processes by which the inputs delivered by different sensory pathways (e.g., visual, auditory, and somatosensory) are integrated are strongly affected by the spatial attributes of stimulation (this is known as the "spatial rule of multisensory integration;" Rowland &Stein, 2008; Stein &Stanford, 2008). Multisensory neurons have multiple excitatory receptive fields (RFs), one for each modality they are responsive to. Interestingly, the RFs of different sensory modalities overlap spatially (i.e., they are in approximate spatial register). Because of this characteristic, if multisensory inputs converge in this overlapping area, as when they originate from the same (or at least proximal) spatial locations, they can sometimes result in an enhancement of the neuronal response. If, on the other hand, the stimuli derive fromspatially disparate locations, one of the stimuli may well fall within the inhibitory region of the neuron, thus determining a response depression. Moreover, multisensory enhancement is typically inversely related to the effectiveness of the single signals to be merged (this is known as the "law of inverse effectiveness;" Rowland &Stein, 2008; Stein &Stanford, 2008).

Particularly interesting in the present context, however, is the so-called "temporal rule of multisensory integration" (e.g., Calvert et al., 2004; Stein &Meredith, 1993; Stein &Stanford, 2008). Namely, only stimuli that occur in close temporal register (and hence that likely originate from the same event) result in response enhancement (i.e., evoke a rate of impulse firing that is significantly higher than the number of impulses evoked by the most effective of these stimuli when presented individually). Typically, the window of temporal tuning of multisensory neurons is a few tens to hundreds of milliseconds wide, with an optimal integration window estimated at approximately 250 ms (Meredith, Nemitz, &Stein, 1987). By contrast, stimuli separated in time just induce responses that are comparable to those evoked by unisensory stimuli (e.g., Beauchamp, 2005; Meredith et al., 1987; see also Kayser &Logothetis, 2007; van Wassenhove, 2009).

Along with the spatial rule and the law of inverse effectiveness, the temporal rule represents a core principle for the neural sensory integration processes and would possibly suggest a functional link between neuronal activity and the behavioral benefits of multisensory integration (see Holmes &Spence, 2005; Stein &Meredith, 1993; though see Holmes, 2007, 2009). Indeed, it has recently been demonstrated that multisensory integration yields a shortening of the latency between the stimulus arrival and the response elicited in an SC neuron (Rowland, Quessy, Stanford, &Stein, 2007). This very early effect parallels the so-called "initial response enhancement," according to which the response enhancement is largest at the beginning of the response (Rowland &Stein, 2008). Both of these neuronal effects trigger and speed up the process by which crossmodal sources of information are integrated as soon the inputs reach the SC. This process results in faster behavioral responses to multisensory events as compared with those evoked by unisensory events (Rowland &Stein, 2008). The links between the neuronal activity and its behavioral effects that have emerged in temporal perception tasks will be discussed more extensively in the sections that follow.

Temporal resolution and temporal order

To the best of our knowledge, one of the first attempts to assess temporal perception within hearing and touch dates back to the 1960s, when Gescheider (1966, 1967a, 1970) measured auditory and tactile temporal resolution (see also von Békésy, 1959). In a series of studies, Gescheider (1966, 1967a, 1970) demonstrated that the skin and ear differed greatly in terms of their ability to resolve successive stimuli (i.e., the temporal resolution thresholds for pairs of brief stimuli presented in rapid succession were found to be 5-10 times higher

for cutaneous stimulation than for auditory stimulation). For instance, two stimuli of equal subjective intensity were perceived as being temporally discrete if they were separated by ~2 ms for monaural and binaural stimulation, but by ~10-12 ms for cutaneous stimulation (Gescheider, 1966, 1967a). Moreover, pairs of auditory stimuli separated by less than 30 ms were perceived as being more disparate in time than pairs of cutaneous stimuli separated by the same temporal interval (Gescheider, 1970). However, when intervals greater than 30 ms were used, pairs of events in both modalities were perceived as equally separated (Gescheider, 1967b).

While Gescheider (1967a, 1967b) compared the temporal perception of auditory and tactile stimuli by testing them separately, Hirsh and Sherrick (1961) conducted the very first study to compare people's ability to judge the temporal features of stimuli presented either within or across different pairs of sensory modalities. They used the temporal order judgment (TOJ) paradigm, in which participants are presented with pairs of stimuli at various different stimulus onset asynchronies (SOAs) and have to judge which stimulus appeared first. It should, however, be noted that the issue explored by Hirsh and Sherrick in their study differs slightly from the one investigated in Gescheider's studies (1967a, 1967b). Indeed, the investigation of the perception of simultaneity or of temporal order likely activates different neuronal mechanisms, whose involvement is traditionally measured through distinct psychophysical estimates (cf. Van Eijk, Kohlrausch, Juola, &van de Par, 2010; van Wassenhove, 2009; Wackermann, 2007). The "fusion threshold" is defined as the frequency (expressed in Hz) at which observers perceive multiple events to be steady, the "simultaneity threshold" is the time interval required for two events to be correctly perceived as successive or simultaneous in time, and the "temporal order threshold" is the amount of time required for two events to be correctly ordered in time.

By measuring the just noticeable differences (JNDs, traditionally defined as the smallest temporal interval at which people can accurately discriminate the temporal order of the stimuli on 75% of the trials), Hirsh and Sherrick (1961) surprisingly found that the temporal separation required to correctly judge the temporal order was approximately 20 ms, in both unimodal (i.e., tactile, auditory, or visual; Experiments 1-3) and multisensory (e.g., audiotactile, audiovisual, and visuotactile; Experiment 4) conditions. Hirsh and Sherrick stated that: "[W]hereas the time between successive stimuli that is necessary for the stimuli to be perceived as successive rather than simultaneous may depend upon the particular sense modality employed, the temporal separation that is required for the judgment of perceived temporal order is much longer and is independent of the sense modality employed." (p. 432)

As we will see, many subsequent studies have provided evidence that has turned out to be fundamentally inconsistent with these claims (see, e.g., Fujisaki &Nishida, 2009; Spence, Baddeley, Zampini, James, &Shore, 2003; Zampini et al., 2005; Zampini, Shore, &Spence, 2003a, 2003b; see Table 1).

For instance, in one recent study, Fujisaki and Nishida (2009) addressed the question of whether people's temporal perception differs as a function of the stimulus modality pairing under investigation. In particular, the authors studied whether there is any difference in terms of the temporal resolution of audiotactile, audiovisual, and visuotactile combinations of stimuli made of either single pulses (whose frequency changed from 1.4 to 26.7 Hz) or else repetitivepulse trains (whose frequency changed between 6.25 and 356.25 Hz). In their experiment, they used a set of paradigms, traditionally used to assess temporal perception, such as a synchrony-asynchrony discrimination task, a simultaneity judgment task (SJ), and a TOJ task. In the synchrony-asynchrony judgment task, participants were presented with stimulus pairs having only one of two magnitudes of asynchrony-0 ms (synchrony) and X ms (asynchrony)- within a single block. The participants had to discriminate between the two alternatives. They were provided with trialby- trial feedback regarding the accuracy of their responses. In the SJ task, pairs of crossmodal stimuli were presented, at a range of different stimulus onset asynchronies (SOAs), using the method of constant stimuli, and the participants had to judge whether the stimuli were presented simultaneously or successively. In the SJ task, the judgments are closely dependent on the criterion adopted by the participants (i.e., their subjective "simultaneous" category), whereas in the synchrony-asynchrony task, they might decide to adjust their judgments in light of the feedback received.

The results of the synchrony-asynchrony judgment and SJ tasks, and-to a lesser extent-of the TOJ task, consistently showed that the temporal resolution of synchrony perception was significantly better for the audiotactile stimulus pairing than for either the audiovisual or visuotactile stimulus pairing. Interestingly, by applying their analysis of the data to those reported by Hirsh and Sherrick (1961), Fujisaki and Nishida (2009) found an analogous pattern of results, with the audiotactile stimulus pairing being processed with a higher degree of temporal resolution as compared with the other sensory pairings. Moreover, the fact that the superior temporal resolution reported for the audiotactile stimulus pairing in the TOJ task is smaller than in the other two tasks suggests a partial dissociation of the perception of temporal order from the perception of simultaneity (see Wackermann, 2007). Furthermore, the threshold required to discriminate synchrony from asynchrony is lower for single- than for repetitive-pulse trains. This was found regardless of the stimulus combination used, possibly suggesting that both single-pulse and repetitive-pulse thresholds for the different stimulus combination may be coded by a common mechanism governing temporal resolution. If we assume that the threshold for single pulse trains indicates the width of the window of simultaneity reflecting the temporal precision of the temporal matching process, then the higher threshold observed for repetitivepulse trains could be suggestive of an increased risk of false matching by the participants in this condition (Fig. 2).

The fact that audiotactile processing has a higher temporal resolution than that of the other stimulus modality pairings can be ascribed, according to Fujisaki and Nishida (2009), to two different explanations, which are by no means necessarily mutually exclusive. The first explanation takes into account the difference in temporal resolution that exists between the various senses. Since vision is known to have a lower temporal resolution than either audition or touch (Welch &Warren, 1980), whenever this sensory modality is involved, performance deteriorates. The alternative explanation takes into account the independent channels model proposed by Sternberg and Knoll (1973). According to their model, the perceived order of two stimuli is determined by evaluating the timing at which stimuli arrive at a central decision mechanism, or "comparator." Fujisaki and Nishida (2009) argue that the higher temporal resolution for audiotactile stimuli reflects the more rapid operation of this comparator for audiotactile pairs of signals. The supposed higher degree of similarity in the temporal profile of the auditory and tactile inputs could possibly induce a facilitation of the comparison of their temporal characteristics as compared with when matching between stimuli presented to other sensory modalities (see also Cappe, Morel, Barone, &Rouiller, 2009; Hackett et al., 2007; Ley, Haggard, &Yarrow, 2009; Wang, Lu, Bendor, &Bartlett, 2008).

Moreover, Fujisaki and Nishida's (2009) study covers the issue of the relationship between synchrony discrimination and temporal order discrimination (cf. Fujisaki &Nishida, 2010). The link between these two kinds of perception is well described by Wackermann (2007):

Temporal experience is primarily experience of succession. The relations of temporal order between events, "A occurs before B," or "A occurs after B," constitute the most elementary form of temporal judgment, preceding a metrical concept of time scale. Our notion of time as a perfectly ordered universe of events implies that any two events, A and B, are comparable as to their temporal order. If A occurs neither before B nor after B, then the events A and B are simultaneous. (p. 22)

This definition suggests that the processing of synchrony and temporal order between sensory stimuli are highly related mechanisms. However, the minimum temporal interval necessary for two stimuli to be perceived as nonsimultaneous (defined as the "fusion threshold;" Exner, 1875) does not coincide with the time interval required to indicate their relative order (what is known as the "order threshold"). This fact has been taken to suggest the existence of multiple brain mechanisms for two different aspects of temporal discrimination (i.e., one for the integration of a unitary percept, another for the determination of succession between different percepts; Hirsh &Fraisse, 1964; Piéron, 1952; van Wassenhove, 2009; see also the section Temporal synchrony and temporal recalibration).

The issue of a centralized versus distributed timing mechanism has been elegantly explored in a recent study

by Fujisaki and Nishida (2010). The authors investigated whether the binding of synchronous attributes is specific to each attribute/sensory combination, or whether instead it occurs at a more central level. By using a psychophysical approach, they measured the processing speed of the judgments of the temporal relationship between two sequences of stimuli (i.e., cross-attribute phase judgments), either within single modalities or crossmodally. The rationale was that, in those cases in which the speed of binding is high and varies as a function of different attribute combinations, the underlying mechanisms are likely to be peripheral and attribute specific. By contrast, a low and invariant binding speed is expected when considering a shared underlying mechanism. In Fujisaki and Nishida's (2010) study, participants had to perform a binding task and a synchrony-asynchrony discrimination task. In the first task, two sequences of stimuli were presented, each of which consisting of the repetitive alternation of two attributes (e.g., in the audiotactile condition, high- or low-pitched sounds were presented together with vibrations to the right or left index finger). The alternations always occurred synchronously between the two sequences, but the feature pairing varied as a function of the in-phase/reversedphase conditions. The participants had to judge which features were presented simultaneously (e.g.,whether the pitch was high or low when the right finger was vibrated). In the synchrony- asynchrony discrimination task, each stimulus sequence contained pulses at a given repetition rate, and the participants had to judge whether the pulses of the two sequences were presented synchronously or asynchronously. The results demonstrated that, whereas the temporal limit on cross-attribute binding was very low (2-3 Hz) and similar for all sensory modality combinations, the synchrony limit varied across the modality combinations (i.e., 4-5 Hz for audiovisual and visuotactile conditions, 7-9 Hz in the audiotactile condition).

Taken together, these results therefore suggest that crossmodal temporal binding and synchrony judgments are governed by different underlying neural mechanisms, with the first process being mediated by a central and amodal mechanism, whereas the perception of crossmodal synchrony appears to be mediated by a peripheral mechanism specific for each attribute combination (Weiss &Scharlau, 2011). However, according to Fujisaki &Nishida (2010), synchrony perception is also centrally represented, as demonstrated by the fact that the temporal limits of crossmodal synchrony perception are still much lower than the limits observed in the individual sensory modalities (cf. Fujisaki &Nishida, 2005). Moreover, synchrony perception is only slightly affected by the attribute combination as long as the modality combination does not change. Therefore, the authors conjectured that both the capability to accurately extract salient changes in time in each sensory channel and to compare them across sensory modalities contributes to improving synchrony judgments. In the binding task, beyond the capability to process the "when" dimension, the capability to judge which combination of stimulus attributes are presented at the same time (the "what" dimension) is also important (see Renier et al., 2009; Yau, Olenczak, Dammann, &Bensmaia, 2009). Thus, the crossmodal temporal binding and the synchrony judgment task would tap into different processes in the perception of an event, thus explaining the discrepancy in the performance observed in the two tasks. However, as pointed out by the authors themselves, the reason why the temporal limit should settle around 2-3 Hz in all of the conditions is unclear, and possibly involves a precise investigation of the timing of high-level sensory processing (Fujisaki &Nishida, 2010).

Spatial effects on the perception of temporal order

An additional aspect to emerge from the literature on TOJ tasks is that audiotactile TOJs seem to be unaffected by the spatial disparity between the stimuli being judged. In a series of experiments, Zampini and his colleagues (Zampini et al., 2005) had participants perform a TOJ task on pairs of stimuli, one tactile and the other auditory, presented at varying SOAs. The stimuli could either be presented from either the same spatial location (i.e., both on the right or the left side of the participant's body midline) or different locations (i.e., one on the right and the other on the left side of the body midline). The results revealed that, contrary to what had been observed previously for audiovisual and visuotactile modality pairings (Spence et al., 2003; Zampini et al., 2003a, 2003b), the audiotactile version of the TOJ task was unaffected by whether the stimuli were presented from the same or different locations (sides). In previous studies, participants were found to be more sensitive (i.e., the results

revealed smaller JNDs; Spence et al., 2003; Zampini et al., 2003a, 2003b) when the stimuli in the two modalities were presented from different spatial positions rather than from the same position (Fig. 3).

The null effect of relative spatial position reported by Zampini et al. (2005) suggests that the audiotactile stimulus pairing may be somehow "less spatial" than the other multisensory pairings involving vision as one of the sensory modalities. These data add to previous research documenting a reduced magnitude of spatial interaction effects for this particular pair of modalities, as compared with the audiovisual and visuotactile pairings, possibly suggesting a finer spatial resolution of visual stimuli than of the auditory and tactile systems (e.g., Eimer, 2004; Gondan, Niederhaus, Rösler, &Röder, 2005; Lloyd, Merat, McGlone, &Spence, 2003; Murray et al., 2005).

Subsequent studies have, however, partially undermined this conclusion, demonstrating instead that the spatial arrangement of the stimuli, and the portion of space stimulated, can differentially affect the nature of the audiotactile interactions that may be observed (Kitagawa, Zampini, &Spence, 2005; Occelli, Spence, &Zampini, 2008). In Kitagawa et al.'s (Experiment 1) audiotactile TOJ experiment, the participants had to judge the temporal order of pairs of auditory and tactile stimuli presented from the left and/or right of fixation at varying SOAs and report which modality had been presented first on each trial. The auditory stimuli were presented from loudspeaker cones, whereas the tactile stimuli were delivered via electrotactile stimulators attached to the participants' earlobes. The results highlighted higher sensitivity (i.e., a lower JND), for stimuli presented from different sides rather than from the same side (i.e., 55 vs. 64 ms).

The discrepancy between the results reported in audiotactile TOJ tasks for stimuli presented from the back and from frontal space (Kitagawa et al., 2005; Zampini et al., 2005) can be explained by taking into account the crucial role of vision in the processing of spatial information in frontal space (Eimer, 2004). That is, audiotactile interactions may be somewhat less "spatial" than other multisensory interactions involving vision as one of the component sensory modalities (e.g., think of audiovisual and visuotactile stimulus pairings; see Spence et al., 2003; Zampini et al., 2003a, 2003b), or when audiotactile stimuli are presented at locations in which visual cues are normally available. By contrast, the lack of visual cues, just as in Kitagawa et al.'s study, may have contributed to a better coding of auditory and tactile spatial cues, which, in turn, could have induced benefits in the processing of their temporal features.

This explanation has recently received further support from another study by Occelli et al. (2008). There, the potential modulatory effect of relative spatial position on audiotactile TOJs was examined as a function of the visual experience of the participants using the paradigm developed by Zampini et al. (2005). The results of Occelli et al.'s study demonstrated that although the performance of the sighted (blindfolded) participants was unaffected by whether or not the two stimuli were presented from the same spatial location, thus replicating Zampini et al.'s earlier findings, the blind participants (regardless of the age of onset of their blindness) were significantly more accurate when the auditory and tactile stimuli were presented from different spatial positions rather than from the same position (see Table 1). Thus, the relative spatial position from which the stimuli were presented had a selective effect on the performance of the blind, but not on the performance of the sighted participants. This pattern of results suggests that the exclusive reliance on those sensory modalities that are typically considered less adequate for conveying spatial information (see Welch &Warren, 1980) failed to induce any advantage in terms of the performance of the blindfolded sighted participants. On the contrary, visual deprivation results in an enhancement of the ability to use the spatial cues available in the intact residual senses (e.g., hearing and touch; see also Collignon, Renier, Bruyer, Tranduy, &Veraart, 2006; Röder, Rösler, &Spence, 2004; Röder et al., 1999). Taken together, these data therefore reveal that the absence of vision (Occelli et al., 2008) or of visual information, as for stimulation occurring behind a participant's head (Farnè &Làdavas, 2002; Kitagawa et al., 2005), seems to be related to more prevalent audiotactile spatial interactions than those occurring in frontal space (Zampini et al., 2005). Moreover, the processing of the spatial cues within touch and audition is improved by presenting the stimuli from that portion of space in which visual cues are

typically unavailable (Kitagawa et al., 2005; Experiment 1) or absent as a result of blindness (e.g., Collignon et al., 2006; Occelli et al., 2008; Röder et al., 2004; Röder &Rösler, 2004).

Temporal synchrony and temporal recalibration

As was already highlighted (see the section Research on Hearing and Touch: A Multisensory Perspective), multisensory integration can take place between stimuli that are not temporally coincident, but which fall within the "temporal window" of integration (Meredith et al., 1987; see also Spence, in press), thus indicating that the merging of information from different modalities can overcome the differences of the senses in terms of conduction speeds, response latencies, and neural processing times (e.g., Lestienne, 2001; Nicolas, 1997; Vroomen &Keetels, 2010). Even though its extent is still a matter of some debate (e.g., Vatakis &Spence, 2010; Vroomen &Keetels, 2010), the existence of a window of temporal tolerance has not only empirical but also theoretical implications (e.g., Pöppel, 2009; van Wassenhove, 2009). Indeed, it implies that the concept of "temporal coincidence" (or "time point;" von Baer, 1864) in perception cannot be experienced in real life, but is rather a construct coinciding not with a specific point in time, but with a window of time. It follows from this that two stimuli falling within this temporal window are likely to be bound together into a single multisensory percept (see also Pöppel, Schill, &von Steinbüchel, 1990). Next, those studies that have investigated the temporal window of integration between auditory and tactile signals will be reviewed.

One series of experiments has investigated people's perceptual sensitivity to simultaneity between haptic and auditory events and whether this would be significantly affected by the physical characteristics of the stimuli that were presented. To address this question, realistic stimulation conditions-such as a hammer hitting a surface or a drum being tapped-were followed by their auditory consequences, and were either executed (Adelstein, Begault, Anderson, &Wenzel, 2003) or filmed (Levitin, MacLean, Mathews, &Chu, 1999). Despite the high between-participants performance variability (see also Begault, Adelstein, McClain, &Anderson, 2005), in both cases, the performance metrics calculated on basis of SJ data observed were significantly different from zero. It can be noted, however, that the values reported in these studies are much smaller than the 80 ms reported in Zampini et al.'s (2005) audiotactile TOJ study. Thus, even though the optimal impression of simultaneity for auditory and tactile stimuli is not perceived when the two stimuli are presented synchronously, it would seem that the conditions of stimulation have an effect in modulating the perceived relative temporal relationship between the stimuli, as measured by JNDs in synchrony/asynchrony tasks (see also Fink, Ulbrich, Churan, &Wittmann, 2006; Vroomen &Keetels, 2010, for other factors affecting the perception of intersensory synchrony). In particular, the use of ecological stimuli, such as those used in the studies of Adelstein et al. and Levitin et al., raises the question of how causality influences multisensory integration. On the basis of a number of recent audiovisual studies, it is known that when the stimulus presented in one modality in some sense predicts the stimulus in the other, multisensory integration is often enhanced (see Mitterer &Jesse, 2010; Schutz &Kubovy, 2009; Vroomen &Stekelenberg, 2010). A similar effect may have affected audiotactile integration in the previously described studies (Adelstein et al., 2003; Levitin et al., 1999), with possibly boosted consequences (i.e., higher tendency to merge multisensory inputs) where visual cues were involved, as in Levitin et al.'s study.

Closely related to the studies just described are those that have assessed the mechanisms of temporal recalibration/ adaption between auditory and tactile stimuli (Hanson, Heron, &Whitaker, 2008; Harrar &Harris, 2008; Levitin et al., 1999; Navarra, Soto-Faraco, &Spence, 2007; Virsu, Oksanen-Hennah, Vedenpää, Jaatinen, &Lahti-Nuuttila, 2008). It has been observed that inputs from different sensory modalities that refer to the same external event (or occur at the same time) will likely reach the cortex at different times, due to differences in the speed of transmission of the signals through different sensory systems (King, 2005; Macefield, Gandevia, &Burke, 1989; Schroeder &Foxe, 2004, 2005; Spence, Shore, &Klein, 2001; Spence &Squire, 2003). It follows from this observation that our perceptual systems need to be able to accommodate a certain degree of asynchrony between the information arriving through different channels.

In the literature on crossmodal integration, it has been demonstrated that the point of subjective simultaneity (PSS; "amount of time by which one stimulus has to precede or follow the other order for the two stimuli to be perceived as simultaneous;" Spence &Parise, 2010, p. 365) measure can be significantly affected by adaptation to asynchrony (see Vroomen &Keetels, 2010, for a review). This process is typically assessed by measuring participants' perceptions of crossmodal simultaneity both before and after exposure to a constant temporal discrepancy between the stimuli that happen to be presented in the two modalities. During the exposure phase of such studies, the perception of asynchronous stimuli should be progressively realigned. As a consequence, the perception of simultaneity changes, in a way that, after exposure, the impression of asynchrony is reduced. There are two candidate mechanisms for the process of temporal recalibration: (a) The realignment of sensory neural signals in time, with the processing of one of the sensory modalities shifting in time toward the other; and (b) The widening of the temporal window for multisensory integration (see Vroomen &Keetels, 2010).

In their study, Navarra et al. (2007) investigated whether exposure to audiotactile asynchrony would induce temporal recalibration between the processing of auditory and tactile stimuli. The participants in their study had to perform an audiotactile TOJ task both before and after an exposure phase in which paired auditory and vibrotactile stimuli could be presented either simultaneously or with the sound leading the vibration by 75 ms. In the exposure phase of the experiment, in order to ensure that participants attended to both auditory and tactile stimuli, they had to perform a control task involving the detection of stimuli that were longer than the standards. Navarra et al.'s results highlighted the fact that exposure to audiotactile asynchrony induced a temporal adaptation aftereffect that influenced the temporal processing of the subsequently presented auditory and tactile stimuli. More precisely, the minimal interval necessary to correctly judge the temporal order of the stimuli was larger after exposure to the desynchronized trains of stimuli (JND = 48 ms) than after exposure to the synchronous stimulus trains (JND = 36 ms), whereas no differences were observed in the PSS (i.e., 11 vs. 5 ms). This result differs from the temporal adaptation process taking place between visual and auditory stimuli, as assessed using similar experimental methods (e.g., Fujisaki, Shimojo, Kashino, &Nishida, 2004; Vroomen, Keetels, de Gelder, &Bertelson, 2004). It thus seems that the audiotactile temporal window is flexible and can be widened in order to compensate for the asynchronies occurring between these stimuli, differently from the audiovisual condition, in which a temporal realignment process seems to take place (cf. Fujisaki et al., 2004). Navarra et al. suggested that the discrepancy between the results could be explained by considering the rare occurrence and the small magnitude of the asynchronies occurring between hearing and touch experienced in everyday life. According to this speculation, the widening of the temporal window of multisensory integration could be considered as a nonspecific mechanism that allows for the integration of-infrequentlyexperienced-audiotactile stimuli presented in close temporal proximity, and the temporal realignment as a more specific compensatory mechanism, suitable for coping with the relatively large asynchronies that may occur between visual and auditory stimuli (Navarra et al., 2007).

Contrasting results have, however, been reported recently. Harrar and Harris (2008) compared the changes in the perception of simultaneity for three different combinations of stimulus modality (i.e., audiotactile, audiovisual, and visuotactile) as a function of the exposure to asynchronous stimulus pairs, which were presented in each of the three stimulus combinations. In contrast with Navarra et al.'s (2007) results, no temporal adaptation (i.e., neither a change of the JND nor of the PSS) was observed for the audiotactile pairings following exposure to any of the three stimulus combinations. According to Harrar and Harris, this discrepancy could be attributed to methodological differences. Specifically, in their study, the tactile (not the auditory, as in Navarra et al.'s [2007] study) stimulus led within the asynchronous pairs. Moreover, the exposure sequences differed not only in terms of their duration, but also in terms of the task that participants had to perform to maintain their attention focused. Further research could therefore help to clarify whether these factors may have contributed to the conflicting results obtained in these two studies (Fig. 4).

Another interesting attempt to explore the crossmodal nature of the temporal recalibration process was reported

recently by Di Luca, Machulla, and Ernst (2009). In their study, the authors investigated whether, and to what extent, the audiovisual temporal recalibration effect transfers to the perception of simultaneity for visuotactile and audiotactile stimulus pairs. The interesting result to emerge from this experiment was that the transfer of audiovisual recalibration of simultaneity to the other pairings of stimulus modalities was dependent on the location from which the stimuli happened to be presented. Specifically, when the stimuli were presented from the same spatial location in front of participants, the audiovisual recalibration effect transferred to visuotactile stimulus pairs (and not to the audiotactile pairings). By contrast, when the auditory stimuli were presented over headphones instead (i.e., when the auditory stimuli were not colocated with the visual and tactile stimuli), the audiovisual temporal recalibration effect transferred to the audiotactile stimulus pairs (and not to the visuotactile pairings). The fact that audiovisual temporal recalibration differently affected the other two sensory pairings could be due, at least according to Di Luca et al., to the different spatial arrangement of the stimuli. More precisely, in the colocation condition, a change in the perceptual latency (and in the reaction time; RT) of the visual stimuli was observed (see Fig. 5a), whereas in the different location condition, a change in the perceptual latency (and in RT) of the auditory stimuli (see Fig. 4b) was observed instead (cf. Sternberg &Knoll, 1973).

Di Luca et al. (2009) argued that the repeated exposure to asynchronous audiovisual stimuli gave rise to the adjustment of the perceptual latency of, separately, the visual or the auditory stimulus. This, in turn, caused a recalibration of perceived simultaneity within the stimulus pairings which, as in Di Luca et al.'s study, were different from those composing the stimuli repeatedly presented during the exposure phase of their experiment. Moreover, the mode of presentation has been shown to affect which signal estimate is trusted more, and hence which signal undergoes a change of temporal latency during recalibration. In Di Luca et al.'s study, when the auditory stimuli were presented over headphones (which constitutes a nonfixed external stimulus source, since it moves when the head moves), the auditory estimate was more likely to be biased (and thus trusted less) than the visual estimate. As a consequence, in this condition, it is the auditory estimate that is temporally recalibrated toward the visual standard. This is seen as an increased transfer to the perception of audiotactile simultaneity as compared with the perception of visuotactile simultaneity. By contrast, when the auditory stimuli were spatially fixed, the visual estimate was more likely to be biased, thus giving rise to an opposite pattern of results (Di Luca et al., 2009).

The fact that temporal recalibration transfers across sensory modality (see also Nagarajan, Blake, Wright, Byl, &Merzenich, 1998, for a study investigating the transfer of temporal rate discrimination from touch to audition) leads on to the crucial question of whether the extraction of temporal rate information should be considered as being coupled to a sensory modality or whether instead it is represented amodally (e.g., see Grondin, 2010; van Wassenhove, 2009; Wittmann, 2009). Despite the remarkable body of evidence accumulated on this topic, the large degree of inconsistency, as highlighted by the data reviewed here, seems to suggest that the exact nature of the temporal features that characterize audiotactile interactions are still unresolved, and thus are certainly worthy of further investigation.

Attention and temporal perception: the prior entry effect

A number of studies have addressed the question of whether temporal perception and, in particular, the impression of temporal simultaneity/successiveness can be influenced by the attentional focus of participants. One of the best-studied attentional effects on temporal perception is the phenomenon of "prior entry" (see Spence &Parise, 2010, for a recent review). According to the law of prior entry (Titchener, 1908), the attended stimuli (or modality) will be perceived sooner than when attention is focused elsewhere (or on another modality). This effect has traditionally been assessed by means of the aforementioned TOJ task, and is measured as a significant difference in the PSS between conditions in which one of the target stimuli is attended as compared with when the other stimulus is attended instead (or when attention is divided).

Studies investigating the audiotactile prior entry effect have demonstrated that the endogenous focusing of an observer's attention on one sensory modality can effectively modulate the perceived temporal relationship

between pairs of stimuli (Sternberg, Knoll, &Gates, 1971; Stone, 1926; see also Sternberg &Knoll, 1973; Van Damme, Gallace, Spence, Crombez, &Moseley, 2009). Moreover, the focusing of a person's attention on a specific location or sensory modality, as well as toward a particular point in time, determines the relative speeding up in the processing of the auditory and tactile stimuli, as shown by Lange and Röder (2006). In their study, participants were presented with short (600 ms) and long (1,200 ms) empty intervals, marked by a tactile onset and an auditory or tactile offset marker (which could consist in a continous stimulation, or in a stimulation with a gap), and, on a block-by-block basis, were asked to attend to one interval and to one sensory modality. The participants had to decide as quickly and as accurately as possible whether the offset marker was a single or a double stimulus. The behavioral and electrophysiological results of this study demonstrated that focusing attention on a particular point in time facilitated the processing of auditory and tactile stimuli. More specifically, participants responded more rapidly to stimuli at an attended point in time as compared with stimuli that were relatively less attended, irrespective of which modality was task relevant. Moreover, an enhancement of early negative deflections of the auditory and somatosensory eventrelated potentials (ERPs; for audition, 100-140 ms; for touch, 130-180 ms) were observed when audition or touch were task relevant, respectively.

These results therefore suggest that the allocation of attention along the temporal dimension can affect the early stages of sensory processing. More interestingly, these data also demonstrate that focusing attention on a particular point in time results in the more efficient processing of stimuli presented in both audition and touch. In contrast with the results obtained in a sustained attention task, such as that conducted by Lange and Röder (2006), no modulation of sensory processing by temporal attention has been detected in a visual temporal cuing paradigm (cf. Griffin, Miniussi, &Nobre, 2001; Miniussi, Wilding, Coull, &Nobre, 1999). Lange and Röder suggested that this discrepancy between the effects seen for different modalities could be attributed to the fact that a sustained attention paradigm, such as that used in their study, could have facilitated a more stable representation of the time interval to be attended to. In this regard, their paradigm differs from the conditions in which the to-be-attended time point changes on a trial-by-trial basis (as in cuing paradigms). This, in turn, could have favored the emergence of earlier effects of temporal attention observed in their study. According to an alternative account for these data, the temporal acuity of audition and touch is simply higher than that of vision (see also Fujisaki &Nishida, 2009).

Numerosity

The decision to review those studies that have investigated numerosity judgments in the present review is supported by the functional link that exists between time and numerosity processing, as first proposed by Meck and Church (1983). In a series of experiments, these researchers demonstrated that rats automatically process duration and number when these two dimensions covary in a sequence of events (i.e., rats were equally sensitive to a 4:1 ratio for both counts and durations, with the other dimension being controlled; see also Brannon, Suanda, &Libertus, 2007, for evidence in children), suggesting that there is a similarity between the processes underlying counting and timing. Interestingly, this effect, which was first demonstrated with auditory inputs, has now been generalized to the case of cutaneous signals. Meck and Church proposed the existence of a single shared representational mechanism (i.e., an "internal accumulator") that supervises both the duration and the numerosity of the events (and, for some authors, their spatial location; see Cappelletti, Freeman, &Cipolotti, 2009; Walsh, 2003).

In a typical temporal numerosity judgment task, a sequence of stimuli (i.e., flashes, beeps, or taps) is presented, and the observer has to try and judge how many stimuli have been presented (e.g., see Cheatham &White, 1952, 1954; Taubman, 1950a, 1950b). The first study to have compared the ability of participants to perform the tactile, visual, and auditory temporal numerosity discrimination of trains of stimuli (consisting of two to nine pulses) presented from a single location at different rates (varying from three to eight pulses per second) was conducted by Lechelt (1975). His results demonstrated that there was a generalized tendency toward the underestimation of the number of pulses, and the number of errors in number assessment was more

pronounced as the number of pulses and/or the rate of stimulus presentation increased. More interestingly, in the context of the present review, was his finding that modality-specific differences were also observed. In all of the experimental conditions, the accuracy in the temporal numerosity judgment task was found to be much higher for audition than for either touch or vision.

A recent study investigated whether the combination of trains of stimuli presented simultaneously in more than one sensory modality could improve people's temporal numerosity estimates (Philippi, van Erp, &Werkhoven, 2008). In contrast with other studies (e.g., Bresciani &Ernst, 2007; Bresciani et al., 2005; Hötting &Röder, 2004; Shams, Kamitani, &Shimojo, 2000) that explored whether there was any interfering effect between sequences of stimuli, the goal of Philippi et al.'s study was to explore whether the presentation of congruent sequences of stimuli would have a beneficial effect on participants' temporal numerosity estimation judgments (see also Lee &Spence, 2008, 2009). The participants in this particular study were presented with sequences (i.e., 2 to 10) of stimuli at interstimulus intervals (ISIs) varying from 20 to 320 ms. The participants were instructed to use the multisensorially redundant information to their advantage when performing the task. Indeed, the results revealed that the degree of underestimation (which has been consistently found in previous unisensory temporal numerosity estimation judgment studies; e.g., Lechelt, 1975; White &Cheatham, 1959) and the variance in participants' estimates were reduced as compared with those in the conditions of unisensory stimulus presentation. The results of Philippi et al.'s study confirmed that visual judgments were worse than the auditory judgments, and that these, in turn, were worse than the tactile judgments (see Lechelt, 1975; White &Cheatham, 1959). Overall, the results showed that the underestimation decreased for smaller ISIs (i.e., 20 and 40 ms) in the multisensory as compared with the unisensory presentation conditions. The authors explained this result by considering that the persistence of brief stimuli hampers the clear separation between rapidly presented within-modality signals, even leading to their fusion, under conditions in which the ISIs are much smaller than the persistence of each individual signal. Of interest for present purposes, Philippi et al. (2008) observed that the difference in temporal numerosity estimation judgments between unimodal auditory or tactile conditions and the bimodal audiotactile condition differed significantly only for short ISIs (20 and 40 ms).

As already mentioned, a large number of previous studies have investigated whether, and to what extent, the presentation of incongruent task-irrelevant multisensory sequences of pulses can influence people's temporal numerosity judgments in the target modality. In the illusory flash paradigm, for instance, people are instructed to report the number of flashes presented with to-be-ignored incongruent sequences of beeps (Shams et al., 2000). The striking result to have emerged from this study was that, when presented with a single flash and multiple auditory pulses, observers typically perceived an illusory second flash. This illusory effect has been explained by taking into account the higher reliability of the auditory modality as compared with the visual modality in the temporal domain (see Shams, Ma, &Beierholm, 2005). This effect, which constitutes a robust perceptual phenomenon, has now been replicated in the audiotactile not to mention visuotactile domains (Bresciani et al., 2005; Bresciani &Ernst, 2007; Hötting, Friedrich, &Röder, 2009; Hötting &Röder, 2004). In one of their studies, Bresciani and Ernst (2007) presented series of beeps and taps and had their participants report on the number of tactile stimuli while ignoring the auditory distractors. The results revealed that participants' tactile perception was modulated by the presentation of taskirrelevant auditory stimuli, with their responses being significantly affected by the number of beeps that were delivered. Such a modulation only occurred, however, when the auditory and tactile stimuli were similar enough (i.e., had the same duration) and were presented at around the same time (see Fig. 6).

According to the maximum likelihood estimation model of multisensory integration (e.g., Alais, Newell, &Mamassian, 2010), the reliability of a sensory channel is related to the relative uncertainty of the information it conveys. The higher the relative variance of a sensory modality, the weaker its relative reliability (Ernst &Bülthoff, 2004). In another study, in order to investigate whether the auditory bias on tactile perception could be disrupted by manipulating the reliability of the auditory information, Bresciani and Ernst (2007) varied the

intensity of the beeps. The auditory stimuli were presented at either 41 or 74 dB (signal-to-noise ratio of, respectively, -30 and 3 dB). They found that the participants were more sensitive (i.e., their estimates were less variable) in counting the number of the more intense (rather than the less intense) beeps presented with the irrelevant taps. Conversely, they were more sensitive in counting the number of taps presented with less intense (vs. more intense) irrelevant beeps (see also Wozny, Beierholm, &Shams, 2008). This pattern of results could reflect the fact that the decrease in the intensity of the auditory stimuli reduced the relative reliability of the auditory modality, thus inducing differential interactions with touch as a function of the intensity of the stimuli. Taken together, these results therefore show that audition and touch reciprocally bias each other (when alternatively used as target or distractor), with the degree of evoked bias depending on the relative reliability of the two modalities (see also Bresciani, Dammeier, &Ernst, 2008; Occelli, Spence, &Zampini, 2009).

To the best of our knowledge, however, the experimental investigations published to date have not applied a multisensory perspective to the assessment of the interactions between time and numerosity (and, possibly, space). Indeed, the currently available data refer to the visual (e.g., Dormal, Seron, &Pesenti, 2006) or auditory (Droit-Volet, Clement, &Favol, 2003; Xuan, Zhang, He, &Chen, 2007) modality, and typically report that when participants perform a numerosity judgment task, temporal intervals are perceived as shorter than their veridical duration. The investigation of this topic using a multisensory approach could lead to a better understanding of the interplay occurring between the mental representation of time, space, number- and, in general, of magnitudes-in both neurologically intact individuals and ultimately in those patients suffering from parietal lesions, a topic which has been, to our knowledge, by now investigated primarily in the visualmodality (e.g., Oliveri et al., 2008, 2009; Vicario, Pecoraro, Turriziani, Koch, &Oliveri, 2008; see also Bueti &Walsh, 2009).

Audiotactile interactions based on frequency similarity

Perceptual interactions between hearing and touch are distinctive from those associations occurring between other pairings of sensory modalities (Gescheider, 1970; Soto-Faraco &Deco, 2009; von Békésy;, 1959; Zmigrod, Spapé, &Hommel, 2009, Experiment 2). As was already mentioned, auditory and vibrotactile stimuli are transduced by the same physical mechanism (i.e., mechanoreception), consisting of the mechanical stimulation of, respectively, the basilar membrane and the skin. Hence, both auditory and vibrotactile stimuli can be described according to their specific periodic patterns of stimulation (i.e., their frequency), defined as the number of repetitions of the sound waveforms (see Plack, 2004; Siebert, 1970) or of tactile pulses (see Luna, Hernández, Brody, &Romo, 2005), respectively, per unit time. Hence, it seems somehow surprising that the investigation of audiotactile interactions as a function of the frequency similarity between stimuli has rarely been carried out to date. Thus far, the focus has primarily been on the perception of lingual vibrotactile stimulation (Fucci, Petrosino, Harris, &Randolph-Tyler, 1988; Harris, Fucci, &Petrosino, 1986, 1989).

The ability of mammals to discriminate frequencies has been considered as reflecting the frequency resolution characterizing the auditory pathway at both the peripheral (i.e., the basilar membrane of the cochlea; Robles &Ruggero, 2001) and central (i.e., the primary auditory cortex; Langers, Backes, &van Dijk, 2007; Tramo, Cariani, Koh, Makris, &Braida, 2005) stages of auditory information processing. The systematic spatial mapping of frequency coding in the brain (known as tonotopy) and the filtering properties of auditory neurons and sensory receptors have been considered responsible for decoding the frequency of auditory stimulation (see Schreiner, Read, &Sutter, 2000, for a review; see also Elhilali, Ma, Micheyl, Oxenham, &Shamma, 2009; Romani, Williamson, &Kaufman, 1982; Schnupp &King, 2008). However, the tonotopic structure of the auditory system is not the only candidate for the representation of the temporal characteristics of auditory stimuli. Indeed, the activity of neurons at different stages of the auditory pathway has been shown to change as a function of the repetition rates of the auditory events being processed (see Bendor &Wang, 2007, for a review). More specifically, acoustic signals within the flutter range (10- 45 Hz) are coded by neurons that synchronize their activity to the temporal profile of repetitive signals. These neurons have been observed both along the auditory-nerve fibers and in the inferior colliculus, the medial geniculate body, and in a specific neuronal

population along the anterolateral border of the primary auditory cortex (AI; Dicke, Ewert, Dau, &Kollmeier, 2007; Oshurkova, Scheich, &Brosch, 2008; Wang et al., 2008). Other mechanisms regulate the activity of the neural population coding for auditory signals presented at higher repetition rates (i.e., above the perceptual flutter range). These neurons modify their discharge rates-not their spike timing-as a function of the frequency of the auditory events that are being processed (Oshurkova et al., 2008; Wang et al., 2008). Thus, the temporal profile of auditory stimuli appears to be represented in AI by a dual process (i.e., stimulus-synchronized firing pattern and discharge rate), each involving specific subpopulations of neurons.

The distinct neural encoding of auditory stimuli differing in frequency may also be responsible for the different perceptual impression conveyed by auditory stimuli. Indeed, when auditory events are presented at rates within the 10-45 Hz (i.e., flutter) range, the resulting percepts tend to consist of sequential and discrete sounds (i.e., acoustic flutter; Bendor &Wang, 2007; see also Besser, 1967). According to Bendor and Wang, the discrete impression of the flutter percept could be considered as the direct outcome of the synchronized responses representing the event at different neural stages of the auditory pathway. On the other hand, neurons encoding stimuli with repetition rates beyond this range do not synchronize with the stimuli, thus failing to induce the impression of discrete auditory events and instead giving rise to continuous-sounding percepts that have a specific pitch (Bendor &Wang, 2007; Hall, Edmondson-Jones, &Fridriksson, 2006; Tramo et al., 2005; Wang et al., 2008).

Interestingly, the perceptual encoding boundary for repetition rates producing low- and high-frequency stimuli seems to be analogous in both hearing and touch (i.e., ~40- 50 Hz). Just as in hearing, the sensation of flutter in touch is induced by periodic trains of impulses at frequencies between ~5 and ~40 Hz (e.g., Romo &Salinas, 2003), whereas higher repetition rates (~40-400 Hz) induce a sensation of "vibration/buzzing" (LaMotte &Mountcastle, 1975; Talbot, Darian-Smith, Kornhuber, &Mountcastle, 1968). Moreover, in the tactile domain, the identification and discrimination of stimuli differing in their frequency relies on the differential sensitivity of sensory receptors and afferent nerve fibers supplying different portions of the skin (Johansson &Vallbo, 1979a, 1979b; Morioka &Griffin, 2005). At the fingertips, the class of fibers classified as fast adapting fibers and the receptors known as "meissner corpuscles" are responsible for the processing of low vibrotactile frequencies (i.e., 5-50 Hz), whereas the pacinian fibers associated with the pacinian receptors are more sensitive to higher vibration frequencies (i.e., higher than 40 Hz; Francis et al., 2000; Iggo &Muir, 1969; Mahns, Perkins, Sahai, Robinson, &Rowe, 2006; Morley, Vickery, Stuart, &Turman, 2007; Talbot et al., 1968; Verrillo, 1985). Animal studies have suggested that one possible candidate for signalling information about the frequency of vibrotactile stimuli is an impulse pattern code, according to which the responses of rapidly adapting afferents are phase locked to the periodicity of the vibrotactile stimulus. The strict correspondence between the temporal features of the vibrotactile stimuli and the impulse patterns have not only been observed in the periphery (i.e., along the sensory nerve fibers), but also in neurons at higher levels along the ascending somatosensory pathway (Hernández, Salinas, García, &Romo, 1997; Mountcastle, Steinmetz, &Romo, 1990; Salinas, Hernández, Zainos, &Romo, 2000).

Even though the encoding of the frequency pattern of vibrotactile stimuli involves all of the stations along the somatosensory pathway, it is likely that more sophisticated processes, such as those involving the discrimination of different frequencies, occur more centrally. In primates performing a frequency discrimination task, the patterns of firing evoked in SI neurons by the comparison stimulus (i.e., usually presented second in each pair) are independent of those elicited by the standard stimulus (i.e., the first stimulus in each pair). It thus seems as though SI is an unlikely candidate for the encoding of the difference between the two stimuli (Romo &Salinas, 2003; Salinas et al., 2000). On the other hand, the fact that the response of neurons in the secondary somatosensory cortex (SII) to the second vibration is affected by the frequency of the first vibration suggests that these neurons contribute significantly to the coding of the frequency difference. Taken together, this evidence therefore suggests that, in primates at least, the perceptual comparison between different frequencies

takes place in SII. Subsequent decisional processes are thought to involve the medial premotor cortex in the frontal lobe area, whose neuronal activity significantly covaried with monkeys' perceptual reports (de Lafuente &Romo, 2005). The similarity of the performance demonstrated by monkeys and humans in detecting and discriminating between stimuli differing in frequency suggests that the neural mechanisms investigated in monkeys may be analogous to those that exist in humans (see Romo &Salinas, 2003; Salinas et al., 2000; Talbot et al., 1968). In humans, just as in monkeys, frequency discrimination does not rely exclusively on SI, but also involves downstream areas, such as SII and some regions in frontal cortex (Harris, Arabzadeh, Fairhall, Benito, &Diamond, 2006).

A recent fMRI study investigated which brain areas are involved in the discrimination of vibrotactile frequency in humans (Li Hegner et al., 2007). The participants in this study had to report whether the sequentially presented vibrotactile stimuli had the same or different frequency. The results revealed that an extended region was recruited during the performance of the task. Beyond the areas typically involved in this kind of task (i.e., SI and SII), other areas, such as the superior temporal gyrus, the precentral gyrus, ipsilateral insula, and supplementary motor area were also involved (Li Hegner et al., 2007). Interestingly, the superior temporal gyrus is known to mediate interactions between auditory and somatosensory stimuli, in both humans (Foxe et al., 2002; Schroeder et al., 2001) and monkeys (Fu et al., 2003; Kayser, Petkov, Augath, &Logothetis, 2005). Neurons in the auditory belt areas respond not only to pulsed tactile stimulation, but also to vibratory stimuli, thus suggesting that the auditory association cortex acts as a cortical location of convergence for auditory and tactile inputs during the discrimination of tactile frequency (Iguchi, Hoshi, Nemoto, Taira, &Hashimoto, 2007; Li Hegner et al., 2007; Schürmann, Caetano, Hlushchuk, Jousmäki, &Hari, 2006; see also Caetano &Jousmäki, 2006; Golaszewski et al., 2006). The evidence suggesting that the auditory areas involved in the processing of tactile stimuli are endowed with specific frequency profiles and contribute to the vibrotactile frequency discrimination processes, raises the intriguing possibility of anatomofunctional similarities between those cortical regions devoted to the processing of the periodicity of both vibrotactile and auditory stimulation.

A study by Bendor and Wang (2007) would appear to suggest that these similarities could, in fact, be the case. These authors distinguished between two populations of neurons in the auditory cortex, known as "positive monotonic" and "negative monotonic." respectively. The first population typically increased its firing rate proportional to the increase of the repetition rates of an auditory stimulus, whereas the second population showed the opposite pattern of responding (see also Wang et al., 2008). Interestingly, neurons with positive and negative monotonic tuning to stimulus repetition rate have not only been observed in the auditory cortex, but also in the somatosensory cortex beyond SI (Bendor &Wang, 2007; Salinas et al., 2000). More specifically, neurons have been detected in SII whose spike rate can be positively or negatively related to the vibrotactile stimulus frequency (Luna et al., 2005; Salinas et al., 2000). The fact that neurons showing positive and negative monotonic tuning to stimulus repetition rate can be observed in both auditory and somatosensory cortices points to a commonality in how these two sensory systems might encode variations in the temporal profile of, respectively, auditory and vibrotactile stimuli (Bendor &Wang, 2007; Wang et al., 2008; see also Soto-Faraco &Deco, 2009), possibly indicating a potential neural basis for the discrimination of frequencies delivered crossmodally (see Bendor &Wang, 2007).

Preliminary evidence from Nagarajan et al. (1998) has suggested that temporal information processing could be governed by common mechanisms across the auditory and tactile sensory systems. In their study, participants were presented with pairs of vibratory pulses and were trained to discriminate the temporal interval separating them. The results not only suggested a decrease in the threshold as a function of training, but also the generalization of the improved interval discrimination to the auditory modality. Even though the generalization was constrained to an auditory base interval that was similar to the one that had been trained in touch, these results are intriguing in suggesting that the coding of temporal intervals could be represented centrally (i.e., shared among different sensory modalities; cf. van Wassenhove, 2009, see also Fujisaki &Nishida, 2010).

Additionally, recent neurophysiological evidence in humans has demonstrated that the discrimination of vibrotactile stimuli can be improved significantly in many people simply by providing auditory feedback- with the same frequency-after the presentation of the tactile stimulation (Iguchi et al., 2007; see Ro, Hsu, Yasar, Caitlin Elmore, &Beauchamp, 2009). The investigation of the neural substrates of this effect led to the conclusion that the increase of the perceptual accuracy and the speeding up of the discrimination of the tactile frequencies were subserved by the coactivation of SII and the supratemporal auditory cortices along with upper bank of the superior temporal sulcus. The data suggest that auditory feedback could have induced a complementary processing of tactile information by means of an intervening process of acoustic imagery. The results of this study therefore add weight to previous investigations showing considerable crossmodal convergence in the posterior auditory cortex of not only tactile stimulation (e.g., Foxe et al., 2002; Kayser et al., 2005), but also of vibrotactile stimulation, in both normal hearing (e.g., Caetano &Jousmäki, 2006; Schürmann et al., 2006) and deaf (Levänen &Hamdorf, 2001) humans.

On the other hand, Yau et al. (2009) demonstrated that auditory stimuli can interfere with tactile frequencydiscrimination responses. The participants in their study had to perform a two-alternative forced choice task judging which of two vibrotactile stimuli (ranging from 100 to 300 Hz, steps of 40 Hz) had the higher frequency. Crucially, the second vibrotactile stimulus was accompanied by an auditory stimulus presented at the same or a different frequency as that of the tactile stimulus. The results revealed a decrement in task performance, but only for auditory distractors in the low frequency range. Interestingly, since the same stimulus proved ineffective in modulating an intensity judgment, and was restricted to the conditions in which the tactile stimulus was presented at- or near-the same frequency, this interfering effect is thought to be highly specific across similar frequencies. Moreover, the perceived frequency of the tactile stimulus was pulled toward that of the auditory stimulus (see also Ro et al., 2009). According to Yau et al., these results are consistent with a supramodal representation of the temporal rate of sensory inputs (cf. Fujisaki &Nishida, 2010; Jones, Poliakoff, &Wells, 2009; van Wassenhove, 2009; see also Ivry &Schlerf, 2008, and the section Conclusions and Directions for Future Research of the present review). This assumption has, however, been challenged by findings demonstrating that the "fusion threshold" differs across sensory modalities, being higher for vision (Landis, 1954) than for audition (Exner, 1875; von Békésy, 1936) and touch (von Békésy, 1959, 1963). Future investigations could possibly better assess the multisensory perception of frequency, by investigating, for instance, if and to what extent people are able to match stimuli having comparable temporal rate features within each modality, and crossmodally.

Audiotactile interactions in rhythm perception and sensorimotor synchronization

Some authors have observed that, whereas the spatial properties of the objects-typically related to visual functions-develop after birth, some temporal properties, such as synchrony, tempo, and rhythm, are experienced during prenatal life, through vestibular, tactile, and auditory stimulation (e.g., Groome et al., 2000; Woodward &Guidozzi, 1992). The different line of development of the sensory modalities would contribute in generating specific "salience hierarchies" for object/event properties, with the processing of auditory-somatosensory synchrony-such as the one elicited by the maternal heartbeat-being one of the first sensory experiences we humans are exposed to (Lickliter &Bahrick, 2000). The experimental evidence demonstrates that not only can the fetus perceive synchrony, but also that from the twentieth week of gestation, fetal motor activity exhibits synchrony with maternal heart rate activity (DiPietro et al., 2006). Moreover, it has been demonstrated that the synchrony of activity between mother and fetus experienced during uterine life significantly influences the shaping the infant's capability to perceive the alternating light-dark in the circadian cycle (Tsai, Barnard, Lentz, &Thomas, 2011), possibly representing a precursor of the mutual responsiveness typifying future social interaction (Reyna &Pickler, 2009).

Given the synchronization experienced with the mother during gestation, primarily based on biological rhythms such as heartbeat or breathing, it should not come as any surprise to find that the capability to discriminate

rhythmic sequences develops very early. In fact, it can be observed by 2 months of age (Trehub &Hannon, 2006). Moreover, infants show a very early capability to recognize and match rhythms that are experienced via multiple sensory channels (see Bahrick, Flom, &Lickliter, 2002; Bahrick &Lickliter, 2004, for evidence on audiovisual rhythm perception). A striking demonstration of this phenomenon comes from a study carried out by Phillips-Silver and Trainor (2005). Infants were trained by being bounced to an ambiguous rhythm (i.e. a rhythm without accents), with half of the infants being bounced on every second beat, and the other half on every third beat. After training, the infants exhibited listening preferences for an auditory version of the rhythm pattern, with accents that matched the way in which they had been bounced (i.e., every second or every third beat). Thus, prior motor experience affected the infants' auditory rhythm preferences. Interestingly, the same authors also observed that, in adults, the movement of the body influenced the auditory encoding of an ambiguous musical rhythm, whereas visual information had no such effect (Phillips-Silver &Trainor, 2005). Thus, it seems that in humans, musical rhythm processing is primarily based on multisensory interactions involving auditory and kinaesthetic systems, which persists for the whole life span (Repp &Penel, 2004; see also Rubinstein, Giladi, &Hausdorff, 2002, for rhythmic auditory sensory cuing in the treatment of motor impairment in Parkinson's disease, and Zatorre, Chen, &Penhune, 2007, for a review on the neural substrates of sensorimotor interactions in music).

Although motor activities often have a somatosensory component, only a few of the studies on this topic have assessed the interactions between auditory and tactile systems in rhythm perception more directly (e.g., Brochard, Touzalin, Després, &Dufour, 2008; Hatta &Ejiri, 1989). For instance, Patel, Iversen, Chen, and Repp (2005) showed that humans have no difficulty in synchronizing finger tapping with sound sequences, but failed to do the same with sequences composed of visual stimuli. On the basis of this evidence, Brochard et al. (2008) investigated whether the sensation of regular pulse is exclusively auditory or whether humans can also feel the metric structure within the somesthetic domain. Participants were asked to synchronize their finger tapping to two identical rhythmic sequences, presented via either the auditory or tactile modality (i.e., short tones or light touches of the fingertip). The results showed that participants were able to extract the metric structure from sequences presented via tactile stimulation as easily as when unimodal auditory stimulation was delivered. The finding that meter can be perceived outside of the auditory modality is consistent with the hypothesis that the representation of temporal periodicity is subserved by brain areas whose activity is modality independent. Subsequent studies have extended this suggestion by demonstrating that the neural activity evoked by either an auditory or tactile rhythmic sequence involves those areas that are primarily involved in stimulus prediction, such as the lateral and mesial premotor areas, as well as areas involved in the analysis of the temporal structure of the stimuli, such as prefrontal, occipital, temporal, and cerebellar areas (Bengtsson et al., 2009). Other research has highlighted the fact that the pattern of common activation during auditory and tactile tapping tasks included both sources that were modality independent and a source that varied with the modality of stimulation (Müller et al., 2008). In the auditory pacing condition, it was localized in the contralateral primary somatosensory cortex, whereas during tactile pacing, it was localized in contralateral posterior parietal cortex. Interestingly, the activity of this third source seems to be involved in the evaluation of the temporal features of the stimulation presented in different sensory modalities. This evidence suggests the intriguing possibility that the processing of sensory inputs with a similar temporal profile is supported by the synchronized oscillatory activities of spatially distributed neuronal population occurring in parallel at different locations in the cortex (Sannita, 2000; see also Engel, König, Kreiter, Gray, &Singer, 1991). According to this hypothesis, the nonlinear endogenous periodicity of the spontaneous oscillatory activity in the neural system is entrained to an external stimulus. This, in turn, results in the transiently activated neuronal aggregates that are separated in space and are pooled in coherent temporal patterns that are functionally related. Thus, according to the "neural resonance phenomena" view, the temporal patterns of sensory stimulation as well as of musical events are perceived because they are intrinsic to the physics of the neural systems involved in perceiving and responding to that

class of percepts (Large &Snyder, 2009).

The investigation of sensorimotor synchronization raises interesting questions relating to the topic of the present review, such as the issue of the temporal features of the interplay between perception and action. A task that has been considered as providing a suitable model to study the production of a periodic pattern of motor acts (tapping or key pressing) in synchrony with a corresponding pattern of stimuli (typically clicks or tones) is the periodic synchronization task (see Repp, 2005, for a review). In this task, the onset of the finger taps usually lead the stimulus onsets by a certain amount of time, ranging from 20 to 50 ms, giving rise to the commonly known "negative asynchrony" effect. Although the reason behind this effect is not yet completely clear, the explanation that currently has the most support claims that this error could be attributed to differences in the nerve conduction time between click and tap and their corresponding central representations (Paillard-Fraisse hypothesis; Fraisse, 1980; see also Aschersleben, 2002, for a coverage of the explanatory models of this effect). Whereas the majority of studies have investigated synchronization to unimodal (typically auditory) stimulus sequences (e.g., Elliott, Welchman, &Wing, 2009; Hary &Moore, 1987; Rivenez, Drake, Brochard, &Guillaume, 2008), a recent study attempted to assess synchronization to multisensory cues (Elliott, Wing, &Welchman, 2010). Participants tapped in time with auditory, visual, and tactile metronomic signals, under conditions of either unimodal or bimodal stimulus presentation. The study showed that when rhythmic cues are presented, the brain weights signals according to the relative reliability in the timing of events across modalities, and the movement production is optimally synchronized to the extracted signals. However, the integration between signals breaks down when there are large temporal discrepancies between cues. In that case, actions are synchronized with the cue with the highest sensory reliability. Typically, in audiovisual and audiotactile combinations, a bias toward audition is observed. This result indicates that when signals are judged as being independent (temporally separated), asynchrony is computed in relation to one of them (often to the auditory signal; Wing, Doumas, &Welchman, 2010). Interestingly, according to the results of Elliott et al.'s research (2010), the temporal window of integration between multisensory cues depends on the sensory modalities involved and the likelihood that the stimulation originates from a common source (see Aschersleben, 2002; Aschersleben &Prinz, 1995). Thus, it seems that our brain is more willing to tolerate a difference in onset time between, for example, a pair of visuotactile stimuli than between a pair of audiotactile stimuli.

Very recent findings in primate studies have shown extensive corticothalamic connections that support the existence of a circuit allowing the rapid integration of somatosensory and auditory signals-processed in remote cortical areas-and the production of a fast motor action to the combination of the two stimuli (seeWang et al., 2008; see also Lim, Bradshaw, Nicholls, &Altenmüller, 2005). For instance, a restricted thalamic area connects remote cortical areas, such as the auditory cortex, area 5, and auditory belt/parabelt areas with associative parietal areas. This pathway could provide the anatomical support for the rapid transmission of auditory and somatosensory information, converging onto the premotor cortex. (Cappe et al., 2009; see also Hackett et al., 2007).

Conclusions and directions for future research

Throughout this review, we have illustrated that the auditory-tactile linkage in the temporal domain is special in a number of important ways. The unique interplay between audition and touch is rooted in the common evolutionary origins of these sensory systems and receptors, and evolves into interactions in different domains, which have been described in the previous sections. As can be inferred from these data, the exact nature of the processes governing crossmodal temporal perception is still far from being completely clear, despite the growing number of studies on this topic, which have been reviewed here. In particular, the fact that the temporal processing of crossmodal signals from the auditory and the tactile channels is privileged-or is at least distinguishable-as compared with the other stimulus pairings, given the analogies occurring between the two sensory systems, has so far received partial support (see Fujisaki &Nishida, 2009). That said, the contradictory evidence on this topic prevents us from providing an unambiguous answer to the question of whether time is

represented centrally, in an amodal way, or is rather differently represented according to the modality of the stimuli processed. Furthermore, we are aware that some of the dimensions regarding the perception of time-such as time-duration perception-have not been covered in this review. However, rather surprisingly, it turns out that these issues have not been investigated extensively thus far in the audiotactile domain. Indeed, playing a musical instrument is a rather complex task. It requires fine temporal accuracy skills (i.e., synchronization, proficient temporal rate, and rhythm processing and reproduction) and the highly proficient coordination of motor activities (closely related with somatosensory and proprioceptive feedback; Drost, Rieger, Brass, Gunter, &Prinz, 2005; Goebl &Palmer, 2008; Huang, Gamble, Wang, &Hsiao, 2010) with their auditory outcomes. Although the consequences of musical training on audiotactile interactions have been explored at the neuronal level (e.g., Lappe, Herholz, Trainor, &Pantev, 2008; Lotze, Scheler, Tan, &Braun, &Birbaumer, 2003; Pantev, Lappe, Herholz, &Trainor, 2009; Pantev et al., 2003; Popescu, Otsuka, &Ioannides, 2004; Schulz, Ross, &Pantev, 2003), there is little behavioral evidence (though see Müller et al., 2008; Pollok, Müller, Aschersleben, Schnitzler, &Prinz, 2004).

Another dimension that is related to musical perception is temporal perception, in particular, the perception of temporal duration which, although extensively studied in the audiovisual domain (e.g., Burr, Banks,& Morrone, 2009; Ulrich, Nitschke, &Rammsayer, 2006; van Wassenhove, Buonomano, Shimojo, &Shams, 2008; Vicario, Rappo, Pepi, &Oliveri, 2009), has rarely been studied in the other sensory domains (though see Goodfellow, 1934; Schutz &Kubovy, 2009). Very recently, however, an EEG study compared the ability of sighted and blind people to discriminate the temporal duration of auditory and tactile stimuli (see van der Lubbe, Van Mierlo, &Postma, 2010). Separate tactile and auditory duration discrimination tasks were conducted, with participants instructed to recognize auditory or tactile targets that were preceded by to-be-ignored tactile or auditory cues to the same or different side as the targets (i.e., valid or invalid trials). The results revealed that the blind had superior duration discrimination abilities as compared with sighted controls. This difference was demonstrated in both the speed and accuracy of their responses. Their proficient performance was accompanied by an enlarged posterior negativity (relative to that seen in the sighted), in both tactile and auditory tasks. Since no reduced orienting effects induced by crossmodal cues were observed in the blind, it seems that changes in information processing in the early blind participants are not attributable to modifications in structures relevant for attentional orienting and alertness, but to a later-supramodal-level of processing instead.

Taken together, these findings support the hypothesis that the enhanced performance and the pattern of activations observed in the blind could reflect a modification at a higher level of information processing, instead of changes in early perceptual processes within the occipital cortex. Furthermore, these data are in line with an amodal, rather than a modality specific, temporal perception process that involves occipital areas in the blind. From these preliminary results, investigating audition and touch separately, it would appear that duration perception in these two sensory modalities could also represent a promising field to be investigated more thoroughly in future research, especially in the clinical field (Meck, 2005). A further issue worthy of investigation could be to find out whether the perception of the duration of auditory and tactile stimuli is prone to crossmodal distortion effects, analogous to what has been found between auditory and visual stimuli (e.g., Chen &Yeh, 2009; van Wassenhove et al., 2008). Moreover, the potential implementation of the experimental findings in the clinical field, such as in sensory substitution (e.g., Minagawa, Ohnishi, &Sugie, 1996), in the diagnosis (e.g., Danckert et al., 2007; Davalos, Kisley, &Ross, 2002; Gilden &Marusich, 2009; Smith, Harper, Gittings, &Abernethy, 2007), or in the treatment (Powers, Hillock, &Wallace, 2009; Thaut, 2005; Vargas &Yu, 2008) of psychiatric and neurological diseases, would be an interesting issue to be investigated in future studies.

Lastly, and as pointed out recently by van Wassenhove (2009), sensory illusions could also offer cues into the conditions under which the perception of the real can be turned into distorted percepts (mainly, but not exclusively, of a spatial nature). Indeed, in this regard, the temporal characteristics of stimulation seem to play a very important role in determining, for instance, the emergence of perceptual illusions (Eagleman, 2008; Grush,

2005), crossmodally (e.g., as in the parchment skin illusion; Guest, Catmur, Lloyd, &Spence, 2002; Jousmäki &Hari, 1998; and auditory-tactile crossmodal saltation; Trojan, Getzmann, Möller, Kleinböhl, &Hölzl, 2009), or in touch and hearing separately (e.g., as in the funnelling illusion, Chen, Friedman, &Roe, 2003; Gardner &Spencer, 1972; Sherrick, 1964; von Békésy, 1959, 1967; Watanabe, 1979; saltation; Geldard, 1985; Hari, 1995; see also Geldard &Sherrick, 1972; and chronostasis; Hodinott-Hill, Thilo, Cowey, &Walsh, 2002; Yarrow &Rothwell, 2003). The discovery of new perceptual illusory phenomena could, in the future, provide clues into the temporal features governing audiotactile interactions.

Author note We thank Paola Rigo and Tommaso Sega for preparing the figures. V.O. is supported by a Departmental Fellowship from the Department of Cognitive Sciences and Education, University of Trento.

Marcia Nappi was tired.

Tired of irritating her husband by, she says, "constantly asking him to repeat everything."

Tired of missing out on conversations at the group dinners she so used to enjoy: "I could only talk to the person next to me."

Tired of no longer experiencing simple everyday joys, such as "the sounds of palm fronds blowing in the wind, and gravel shifting under my feet."

But, most of all, the part-time Jupiter resident was tired because she had to expend so much extra energy compensating for her hearing loss. "It's exhausting to try to live normally when you can't hear," she says.

So Nappi, 76, did something about it: "Twenty years ago, I got my hearing checked and began wearing hearing aids. It changed my life."

With improved hearing, Nappi began enjoying life again. But the devices weren't perfect.

"Back in those days, my hearing aids couldn't filter out background noise, so they were uncomfortable to wear in noisy environments like restaurants," she recalls.

A decade ago, she upgraded to new equipment. The technology was "much improved-- but my own voice didn't sound natural to me. Rather, I felt like I was talking into a microphone," Nappi says.

Last fall, she upgraded again-- this time, to a digital, manually adjustable model from NuEar-- and is ecstatic. "It's the truest, most natural sound in the world. They're amazing!" she gushes.

Nappi's experience is common, says Leonard Zinni, a licensed, board-certified hearing-instrument specialist and the president/owner of Advanced Hearing Center in Juno Beach.

"The technology on today's hearing aids is so far superior to what we used to have that I tell my patients, 'If it doesn't sound right, it's because it's not properly fitted or fine-tuned,'" he says.

Indeed, Zinni explains that, unlike with eyeglasses, "Hearing aids often require a gradual adjustment period-- and then ongoing evaluation. A good hearing specialist develops a relationship with his or her patients and guides them through the process."

Age-related hearing loss occurs so gradually, so insidiously, over the decades that, according to audiologist Dr. Lynn Weinberg of Professional Audiology Associates in Jupiter, "Many people do not recognize that they have hearing loss until either a family member or a friend tells them."

Weinberg notes that around one in six Baby Boomers has some hearing loss, and that, by age 65, the ratio increases to one in three.

But hearing loss impacts more than just the patient. As Zinni points out, "Your hearing loss affects everyone you come into contact with: your family, friends, co-workers, everybody."

Therefore, Zinni recommends that anyone who suspects he or she is suffering from hearing loss do something about it-- immediately.

"Reputable hearing-aid specialists will do complimentary initial exams, with no commitment required on the part of the patient," he explains.

These quick, painless exams should include a video ear inspection (to rule out any potential medical issues in the outer ear canal), as well as audiometric testing to determine what sound frequencies a patient is-- and isn't-- hearing.

Take action

What Zinni and Weinberg stress is that, left untreated, hearing loss can lead to, or exacerbate, a host of other serious conditions.

Warns Zinni: "Numerous recent studies have linked untreated hearing loss to impaired cognitive skills and a decrease in memory."

What's more, Weinberg points out, "Compromised hearing can lead to social isolation, withdrawal, depression, and even be mistaken as an early sign of dementia."

One of the biggest hurdles that those in the hearing industry face: their patients' vanity. And this vanity is on display in both genders, albeit often for different reasons: women, because of the fashion aspect; men, because they don't want to appear weak.

With today's stylish and/or virtually invisible devices, vanity should no longer be an obstacle.

But on the rare occasions when it still is, Zinni tells such patients, "A hearing aid is far less conspicuous than your hearing loss."

EL-Egance hearing aid (shown on model in photo on Page 1D): Designed by Ryan Kirkpatrick, this equipment is part hearing aid, part jewelry. In addition to the ear pieces, the 'controls' come in the form of rings that the user wears on her index fingers-- and the display case doubles as a charging station for all the pieces.

Wirear hearing aid: Created a few years back by a university student in Australia, this piece is flexible, comes in several colors, and uses a 'micro fuel cell' to increase longevity.

Grandpa's bulky, manila-colored hearing aid is long gone. Today's auditory enhancers are sleek, lightweight and, to satisfy the fashion-conscious, come in a variety of colors. For more styles, log on to www.hearingaidsforwomen.com

Siemens Life hearing aid: Now you can match your outfit to your hearing aid with this line of fun, brightly colored devices.

Hear better ... and still look good!Behind the ear: The hearing technology is behind the ear, and a thin acoustical wire attaches to the canal.

Receiver in the canal: With this style, the speaker fits inside the ear canal.

In the ear: These pieces are custom-fitted to the exact ear shape of the user.
In the canal half-shell: Custom-fitted and smaller than in-the-ear pieces.
Completely in the canal: Barely visible, this is custom-fitted.
Invisible in the canal: Custom-fitted and placed so far into the ear canal that it can't be seen by anyone.

Signal Processing; New Signal Processing Study Results Reported from University of Colorado

Author: Anonymous

Publication info: Electronics Business Journal (May 11, 2011): 1114.
ProQuest document link

Abstract: The researchers concluded: "The average quality ratings for music were reasonably well predicted by the hearing aid speech quality index (HASQI), but additional work is needed to optimize the index to the wide range of music genres and processing conditions included in this study."

Full text: 2011 MAY 11 - (VerticalNews.com) -- "The purpose of this study was to determine the relative impact of different forms of hearing aid signal processing on quality ratings of music. Music quality was assessed using a rating scale for three types of music: orchestral classical music, jazz instrumental, and a female vocalist," scientists in Boulder, United States report.
"The music stimuli were subjected to a wide range of simulated hearing aid processing conditions including, (1) noise and nonlinear processing, (2) linear filtering, and (3) combinations of noise, nonlinear, and linear filtering. sample: Quality ratings were measured in a group of 19 listeners with normal hearing and a group of 15 listeners with sensorineural hearing impairment. Quality ratings in both groups were generally comparable, were reliable across test sessions, were impacted more by noise and nonlinear signal processing than by linear filtering, and were significantly affected by the genre of music," wrote K.H. Arehart and colleagues, University of Colorado.
The researchers concluded: "The average quality ratings for music were reasonably well predicted by the hearing aid speech quality index (HASQI), but additional work is needed to optimize the index to the wide range of music genres and processing conditions included in this study."
Arehart and colleagues published their study in International Journal of Audiology (Effects of noise, nonlinear processing, and linear filtering on perceived music quality. International Journal of Audiology, 2011;50(3):177-190).

(Tracking ID # 7411)
BACKGROUND: Urinary incontinence is a common but under-diagnosed and under-treated problem in women. The traditional extended evaluation for urinary incontinence is difficult to perform in the primary care setting, creating a significant barrier to treatment. A simple 3-item measure to diagnose and classify incontinence in women (the 3 Incontinence Questions) was developed to facilitate diagnosis and treatment of this problem. However, the efficacy and safety of using this measure to initiate treatment for incontinence are unknown.
METHODS: In this double-blind, multicenter, clinical trial, 645 ambulatory women who self-identified as having urgency-predominant
incontinence using the 3 Incontinence Questions and denied other major urologic or neurologic co-morbidities were randomized to 12 weeks of pharmacologic therapy with fesoterodine (participant-directed dosing of 4 to 8 mg daily)(N=322) or placebo (N=323). Frequency of urgency incontinence and other urinary symptoms was assessed at baseline and 12 weeks using voiding diaries in which women recorded all incontinence and voiding episodes over a 3-day period. Safety was assessed through adverse event monitoring and measurement of post-treatment postvoid residual volume (PVR), with specialist referral for PVR of 250 mL or greater or clinical

safety concern. Treatment effects on urinary symptoms and safety outcomes were examined using analysis of covariance models, with adjustment for baseline values as well as clinical site.
RESULTS: Mean (SD) age of participants was 56 (14) years, and mean (SD) baseline urgency incontinence frequency was 3.9 (3.0) episodes per day. After 12 weeks, participants in the fesoterodine group reported an average of 0.9 fewer instances of urgency incontinence, 1.0 fewer instances of total incontinence, and 0.9 fewer urgency-associated voids per day, compared to placebo (P.001 for all). Four serious adverse events occurred in each treatment group; no serious adverse events were related to pharmacologic therapy. Mean (SD) postvoid residual volume after 12 weeks was 39 (48) mL in the fesoterodine versus 31 (39) mL in the placebo group (P=.04). No participant developed a post-treatment PVR of 250 mL or greater or required specialist referral for a safety concern.
CONCLUSION: Among ambulatory women with urgency urinary incontinence diagnosed using a simple 3-item measure, pharmacologic therapy with fesoterodine resulted in a moderate decrease in urgency incontinence frequency, without causing significant urinary retention or increasing serious adverse events. These findings support the initial efficacy and safety of a streamlined diagnostic and treatment algorithm for urgency incontinence among women who are appropriate for evaluation and treatment in primary care.

(Tracking ID # 7438)
BACKGROUND: Data regarding the association between subclinical hyperthyroidism and cardiovascular outcomes are conflicting among large
prospective cohort studies. This might reflect differences in participants age, gender, thyroid-stimulating hormone (TSH) levels or preexisting cardiovascular disease. We aimed to assess the risks of coronary heart disease (CHD) and total mortality associated with subclinical hyperthyroidism. METHODS: We searched MEDLINE and EMBASE without language restrictions, and reference lists of retrieved articles to find prospective cohort studies with baseline thyroid function assessment and follow-up of subsequent total mortality, CHD mortality and CHD events. Individual data on 49,030 participants with 458,686 person-years of

follow-up between 1981 and 2007 were supplied from 9 prospective cohorts in the United States, Europe, Australia and Brazil. We examined the risk of CHD events in 22,676 participants from 6 cohorts with available data. Euthyroidism was defined as a TSH 0.45-4.49 mIU/L and subclinical hyperthyroidism as a TSHRESULTS: Among 49,030 adults, 1,300 had subclinical hyperthyroidism (2.7%) and 47,730 had euthyroidism. During follow-up, 7,988 participants died (1,794 of CHD); 3,740 out of 22,676 participants had CHD events. After exclusion of thyroid-altering medication users at baseline (N=239, 0.5% of all participants), age and gender-adjusted risks of total mortality, CHD mortality and CHD events were increased (Table), with limited statistical heterogeneity across studies (I square=0% to 33%). Risks of total and CHD mortality were increased with lower TSH levels (Table), although borderline significant for total mortality (p for trend 0.053 and 0.01, respectively). Risks did not significantly differ by age, gender, race, or preexisting cardiovascular disease. Results were similar after further adjustment for cardiovascular risk factors.

CONCLUSION: Subclinical hyperthyroidism is associated with an increased risk of total and CHD mortality. The risks are higher with lower TSH, particularly in those with TSH below 0.10 mIU/L. Future studies should assess which conditions increase the risk of total and cause-specific mortality associated with subclinical hyperthyroidism.

Table 1:

No. outcomes / participants	TSH <0.45 mIU/L vs. euthyroidism: HR (95% CI)	TSH 0.10-0.44 vs. euthyroidism: HR (95% CI)	TSH <0.10 vs. euthyroidism: HR (95% CI)	P for trend *

BACKGROUND: Studies of diagnostic reasoning have identified an intermediate effect, where mid-level learners generate more propositional assertions than novices or experts when solving clinical problems. Expert knowledge is encapsulated rather than being lost or disconnected. None of these investigations have studied premedical students. We report here on part of a larger study about the nature of expert knowledge encapsulation.

METHODS: Semi-structured interviews were audio taped for ten each of premedical students (P), first year medical students (MS1), third year medical students (MS3), second year medicine residents (R), and experienced medicine faculty (F). Simultaneously, a process observer recorded emotional tone using a validated tool. Transcripts blinded to learner level were created. Transcripts were analyzed in two ways. One team used grounded theory, identifying salient categories in the data, coming to agreement about the set of categories, and scoring each passage for these categories. Another analyst performed a propositional analysis, identifying IF-THEN assertions and organizing these into propositional maps.

RESULTS: Grounded theory analysts identified 17 salient categories in the transcript data. Inter-rater reliability after a single adjudication session was 81% and was 92% for the final analyses. The category for this analysis struggling with disease definition was scored as follows [Group (# text units)}: PM (117), MS1 (174), MS3 (17), R (24), and F (1). For example, Ill never be able to learn that muchbut something thats really helped, knowing people who have done it. I mean the fact that there are doctors, doctors exist, so it must be possible (MS1). Also, the number of text units in the categories history and disconfirming example increased with expertise, while the number in physical and tests peaked at the R level. The average number of propositions per group was as follows: PM 4.2+/2, MS12.3+/ 1.8, MS3 8.4+/3.1, R 12.4+/5.4, and F 9.6+/4.2. The word count per transcript steadily increased with expertise. Propositional maps for MS1s were blunted compared with all other groups, and focused on a desire for concreteness. For instance, I feel like labs would help a lotx-rays or CT scans (MS1). Emotional tone averaged 0.23 (aroused) for PM, -0.067 (tense) for MS1, 0.42 (alert) for MS3, 0.51 (alert) for R, and 0.78 (excited) for F. One R scored sad (recounting a patient who had recently died) and three F were the only interviewees to score calm.

CONCLUSION: Triangulation between grounded theory categories, propositional analysis, and process observation suggest that the MS1 year is particularly difficult. Much of this difficulty is due to the volume of information and the lack of an organizing conceptual structure. It is not known whether this is a developmental or curricular effect.

NO TIME TO THINK ABOUT HEATH: EXPLANATORY MODELS OF CARDIOVASCULAR DISEASE AMONG BENGALI IMMIGRANTS Mihir Patel 1; Lhasa Ray 2; Erica Phillips-Caesar 1; Carla Boutin-Foster1.
1Weill Cornell Medical College, New York, New York ; 2New York Presbyterian Hospital, New York, New York .
(Tracking ID # 7487)

BACKGROUND: Bengalis, a South Asian ethnic subgroup, make up an increasing portion of the South Asian immigrant population and have the highest prevalence, the earliest onset, and the most severe manifestations of cardiovascular disease (CVD) among all South Asian subgroups. Few studies have focused on the explanatory models of cardiovascular disease among the Bengali population. The objective of this study was to apply Kleinmans Explanatory Model of Disease as a framework to elicit perspectives on cardiovascular disease among a cohort of Bengali immigrants.

METHODS: This was a qualitative study conducted among patients of Bengali origin who were recruited from a Federally Qualified Health Center in New York City. These health centers provide comprehensive community based primary care and social services to underserved communities. Eligible patients were those identified from the practice site that were 18 or older and able to speak English. Demographic data also included years of

residence in the US and acculturation assessment. The electronic medical records were used to collect data on cardiovascular risks such as height, weight, lipid profile, and blood pressure. Individual interviews using open-ended questions based on Kleinmans model were used to identify an explanatory model of cardiovascular disease. Participants were asked to reflect on experiences that they or members of their social network (friends, co-workers, or family) had with heart disease and describe what cardiovascular disease meant to them, what they thought caused it, and how it could be prevented.
RESULTS: A total of 60 Bengali patients were interviewed with two-thirds being male patients. The average age was 43 years. The average length of time in the U.S. was 16 years and 5 months, while the Marin acculturation score averaged moderately low at 8.6. Half of subjects finished college, yet most worked in semi-skilled jobs. Two-thirds of patients were obese by BMI and 88% displayed central obesity. Fifty-nine percent were sedentary expending less than 1000 kcal of energy per week. Mean blood pressure was 111/70 mm Hg. Average total cholesterol was 172 mg/dL, mean LDL was 102 mg/dL, mean HDL was 41 mg/dL, and mean triglyceride level was 155 mg/dL.
The most frequent themes surrounding the meaning of CVD involved stress and fear. For example, one participant said, Its very very scary. If this should happen (to me) what would I do? Much of these perceptions stemmed from experiences a relative had rather than their own personal

experiences. The major themes describing causative factors included having too much stress related to work and caring for ones family as well as lack of time to practice healthy lifestyle habits. Acquiring CVD was felt to be related to hard work and not taking proper rest. I have to take care of my family in Bangladesh and here. I have to think about too much stuff. Another patient said that because of no time we dont think about health, we think about other things. Themes regarding how to prevent CVD included individual physician guidance on healthy lifestyles as well as education targeting the entire Bengali community. For example, one participant explained that others need a lot of help. They need to have a Bangladeshi doctor, diet, and exercise. Another said, Actually we should alert people, I think a talk show would be great, you know on Bengali channels.
CONCLUSION: These findings point to several culturally patterned belief systems about cardiovascular disease that need to be integrated when developing interventions or counseling individual Bengali patients about CVD. The meaning, the etiology, and the prevention of cardiovascular disease were all centered around the major theme of stress related to work and of taking care of the family in the US and back home in Bangladesh. These findings will be used to develop a community-based intervention that focuses on stress reduction, work-life balance and education about lifestyle habits.
DURATION OF THE RISK OF VTE IN US MEDICAL PATIENTS Alpesh Amin 1; Helen Varker 2; Jay Lin 3; Stephen Thompson 4; Stephen Johnston2. 1University of California-Irvine, Orange, California ; 2Thomson Reuters, Washington, District of Columbia ; 3Bruce Wong &Associates Inc., Radnor, Pennsylvania ; 4sanofi-aventis U.S., Inc, Bridgewater, New Jersey . (Tracking ID # 7502)
BACKGROUND: The risk of developing venous thromboembolism (VTE) is significantly increased in patients hospitalized for medical illness. The incidence and time course of VTE events following hospitalization for medical illness was retrospectively assessed in a large, real-world patient population. METHODS: Administrative claims data derived from the Thomson Reuters MarketScan Inpatient Drug Link File were used to identify patients with hospitalization for severe infectious disease, congestive heart failure, cancer, or chronic obstructive pulmonary disease. Included patients had been admitted to hospital between January 1, 2005, and December 31, 2008. Included patients had been continuously enrolled for >12 months prior to admission (patient history) and >180 days after admission, and were required to have received any pharmacological prophylaxis during their hospitalization. The cumulative risk and hazard of VTE measured as the number of VTE events per 1,000 person-days were established across an evaluation period of 180 days.
RESULTS: The study cohort consisted of 5,200 medical patients, with a mean (standard deviation [SD]) age of

68.9 (13.0) years and 51.0% were female. The mean (SD) length of stay in hospital was 6.5 (6.1) days, during which patients received VTE prophylaxis for a mean (SD) duration of 5.0 (4.7) days. 16.0% of patients received anticoagulation therapy within the period extending from discharge to 35 days after discharge. Appropriateness of prophylaxis was not determined. A total of 239 VTE events occurred during the 180-day evaluation period and 127 (53%) of these events occurred during the index hospitalization. The highest number of VTE events occurred during the first 9 days (71 events, 89% in-hospital; proportion of 180-day cumulative risk ~20%) and during days 1019 (64 events, 78% inhospital; proportion of 180-day cumulative risk ~52%) following index admission. VTE hazard peaked at approximately 1.7 per 1,000 person-days on the 8th day following admission, and 50% had been incurred by the 18th day. VTE frequency then further decreased
during days 2029 (17 events, 47% in-hospital; proportion of 180-day cumulative risk ~62%) and gradually declined thereafter, fluctuating at a background level of 19 events during each 10-day interval up to 170180 days.
CONCLUSION: Among the cohort of 5,200 at-risk medical patients who received pharmacological prophylaxis for VTE, 4.6% experienced an incident VTE event during the 180-day evaluation period following index hospitalization. Half of these events occurred post-discharge. The risk of VTE was highest within the first 19 days after index admission. Results from this study indicate that a non-trivial risk of VTE extends into the period after discharge. Acknowledgment: This study was funded by sanofi-aventis U.S., Inc. The authors received editorial/writing support in the preparation of this abstract provided by Tessa Hartog, PhD, of Excerpta Medica, funded by sanofi-aventis U.S., Inc.
INTERPERSONAL DISCRIMINATION AND HEALTH UTILITY SCORES AMONG BLACK AND WHITE MEN AND WOMEN IN THE UNITED STATES Janel Hanmer 1; Sherrill Sellers 2; Dasha Cherepanov 3; Dennis Fryback4. 1University of Iowa, Iowa City, Iowa ; 2Miami University, Oxford, Ohio ; 3UCLA, Los Angeles, California ; 4University of Wisconsin, Madison, Wisconsin . (Tracking ID # 7628)
BACKGROUND: Very little is known about the prevalence of discrimination across race and gender. While discrimination has been shown to impact health, no studies to date have examined the association between discrimination and health utility scores.
METHODS: We examined data from the National Health Measurement Study(NHMS), a nationally representative sample of 3844 adults aged 35 to 79 in the non-institutionalized US population. These data include self-reported lifetime and everyday discrimination as well as several health utility indexes (EQ-5D, HUI3, and SF-6D used here). Weighted health utility means and percentages for discrimination were computed separately within four gender by race subgroups. Each gender by race group was further stratified by discrimination scale scores and multiple regression to compute mean HRQOL scores adjusted for age, income, education, and chronic diseases. All analyses used survey weights to account for the sampling design of NHMS.
RESULTS: Black men reported the highest lifetime discrimination scores, followed by black women; white women tended to report the least lifetime discrimination. The distribution of everyday discrimination scores was very similar for black men and women; white mens and womens scores shifted toward the low-discrimination end of the scale compared to blacks. Health utility tended to get worse as reported discrimination increased. With a few exceptions, differences between mean health utility scores in the lowest and highest discrimination groups exceeded the 0.03 difference generally considered to be a clinically significant difference.
CONCLUSION: Persons who experienced interpersonal discrimination tended to score lower on health utility measures. Understanding the pathways by which discrimination may impact health utility scores is important if we are to improve health-related quality of life.
INCIDENCE OF CARDIOVASCULAR EVENTS FOLLOWING HOSPITAL ADMISSION FOR PNEUMONIA Eric Mortensen 1; Theodore Perry 2; Brandy Nakashima 3; Marcos Restrepo 1; Antonio Anzueto2. 1VERDICT/ STVHCS, San Antonio, Texas ; 2UTHSCSA, San Antonio, Texas ;

3VERDICT/STHVCS, San Antonio, Texas . (Tracking ID # 7793)
BACKGROUND: Studies suggest an increased risk of cardiovascular events, primarily acute myocardial infarction, around the time of hospital admission for pneumonia. Therefore we examined incident

cardiovascular events, including myocardial infarction, congestive heart failure, unstable angina, stroke, and serious cardiac arrhythmias, within 90 days after hospitalization for pneumonia.
METHODS: Using data from the administrative databases of the Department of Veterans Affairs, we examined a cohort of subjects hospitalized with pneumonia between October 2001 and September 2007. Subjects were at least 65 years of age. We examined the incidence of an inpatient diagnosis of myocardial infarction, congestive heart failure, cardiac arrhythmias, unstable angina, and stroke by ICD-9 codes excluding those with the same diagnosis prior to the admission for pneumonia. RESULTS: The cohort comprised 50,119 subjects with a mean age of77.5 years (standard deviation 6.7 years), and 98% of the cohort was male. The 90-day incidence of cardiovascular events was 1.5% for myocardial infarction, 10.2% for congestive heart failure, 9.5% for arrhythmia, 0.8% for unstable angina, and 0.2% for stroke. The majority of events occurred during the initial hospitalization for pneumonia. CONCLUSION: A clinically important number of subjects in this cohort suffered a cardiovascular event within 90 days of hospital admission, suggesting that such events may have an important role in post-pneumonia mortality. Additional research is needed to determine whether interventions may reduce cardiovascular events after pneumonia.
ADIPONECTIN AND ALL-CAUSE MORTALITY IN A COHORT OF ELDERLY PEOPLE WITH TYPE 2 DIABETES Jessica Rohman Singer 1;
Walter Palmas 1; Steven Shea 1; Jose Alejandro Luchsinger1. 1Division of General Medicine, Department of Medicine, Columbia University College of Physicians and Surgeons, New York, New York . (Tracking ID # 7871)

BACKGROUND: Nearly a quarter of Americans over the age of 60 are estimated to have type 2 diabetes. The Action to Control Cardiovascular Risk in Diabetes Trial demonstrated that tight glycemic control was associated with increased mortality, while tight lipid and blood pressure control had no association with mortality. These surprising findings raise the possibility of novel predictors of mortality in people with type 2 diabetes. We sought to explore whether insulin resistance measured by adiponectin level was related to increased mortality in people with type 2 diabetes. High levels of adiponectin are known to be associated with lower risk of developing type 2 diabetes, but no data have been published to our knowledge regarding the association of adiponectin level and mortality specifically in patients with type 2 diabetes. Data regarding adiponectin level and mortality in non-diabetic populations are inconsistent. METHODS: Participants were a subsample of 627 subjects from the Informatics for Diabetes Education and Telemedicine project (IDEATel) who were enrolled in a substudy. IDEATel was a CMS supported randomized controlled trial designed to evaluate the effectiveness of telemedicine case management in elderly Medicare beneficiaries with type 2 diabetes but without severe co-morbid disease. Subjects were enrolled in IDEATel from December 2000 to October 2005. Adiponectin was measured on frozen serum samples for all subjects and mortality data were collected from the National Death Index through 11/30/2009. ANOVA and Chi-square were used to compare relevant continuous and categorical variables across quartiles of adiponectin. Cox proportional hazards regression was performed to examine the relationship between adiponectin level and all-cause mortality adjusting for age, gender, race/ ethnicity, hemoglobin A1c, blood pressure, LDL, HDL, triglycerides, BMI, albumin/creatinine ratio, c-reactive protein, active tobacco use and medication usage, specifically thiazolidinediones (TZDs).
RESULTS: Subjects had a mean age of 72, were 70% women, 83% Hispanic and 15% African American. Compared to the lowest adiponectin quartile, those in the highest adiponectin quartile had higher HDL

(51.4+/16.7 vs. 42.7+/12.3; p< 0.001), higher log albumin/
creatinine (1.6+/0.6 vs 1.3+/0.5; p=0.0037), higher frequency of TZD use (58.6% vs. 5.8%; p<0.0001), lower triglycerides (121.6+/61.3 vs 144.6+/77.9; p=0.005) and lower CRP (0.3+/1.3 vs. 1.0+/1.3; p<0.0001). Cox regression models demonstrated that compared with those in the lowest quartile of adiponectin, those in the highest adiponectin quartile had an increased hazard of death with a fully adjusted hazard ratio of 4.0 (95% CI 1.7, 9.2); p-value=0.0003 for trend across quartiles of adiponectin level (Table 1). These results remained consistent when the analysis was stratified by age, gender and TZD usage and after excluding those subjects who died within one year of adiponectin sampling. We conducted a secondary analysis in a sample of 464 participants for whom we were able to calculate change in weight predating the adiponectin measurement. After adjustment for weight gain or loss of more than 10% of body weight, the association between adiponectin and higher mortality remained significant with a fully adjusted hazard ratio of 3.1 (95% CI 1.2, 7.9); p=0.01 for trend across quartiles of adiponectin level.
CONCLUSION: Higher adiponectin level was associated with higher all-cause mortality in a cohort of elderly people with type 2 diabetes.

Adiponectin Quartile Hazard Ratio (95% CI) 1 Reference2 1.5 (0.7, 3.5)3 2.8 (1.3, 6.2)4 4.0 (1.7, 9.2)p-value for trend 0.0003
A RANDOMIZED PILOT TRIAL OF A FULL SUBSIDY VERSUS A PARTIAL SUBSIDY FOR OBESITY TREATMENT Adam Gilden Tsai 1;
Sue Felton 1; James O. Hill 1; Adam J Atherly1. 1University of Colorado, Denver, Colorado . (Tracking ID # 7895)
BACKGROUND: Federal health care reform stipulates that services receiving an A or B recommendation from the U.S. Preventive Services Task Force will be covered without cost sharing. One such service is intensive weight loss counseling. Intensive counseling is costly ($1200 per person in the first year of the Diabetes Prevention Program). The need to provide treatment must be balanced against cost. A partial subsidy has been modeled as a cost-effective way to deliver obesity treatment. This pilot randomized trial tested the feasibility and initial efficacy of a partial versus a full in-kind subsidy during a short term weight loss program. We hypothesized that full subsidy of the program, as compared to partial subsidy, would lead to similar weight lossesi.e., delivering equal clinical benefit at lower cost.
METHODS: Participants were recruited from primary care practices at the University of Colorado. They had a body mass index of 3049.9 kg/ m2, plus one related medical diagnosis: 1) type 2 diabetes; 2) hypertension; 3) dyslipidemia; or 4) obstructive sleep apnea. They were randomized to receive 2 meals per day of portion-controlled food (full subsidy) or to receive 1 meal per day (partial subsidy) for a period of 14 weeks. Participants randomized to the partial subsidy condition were advised to purchase 1 meal per day of portion-controlled foods on their own. Weight loss counseling (8 visits) was provided without cost to all participants. Visits were led by a trained lay provider. Written materials were adapted from the Diabetes Prevention Program. The primary outcome was weight loss. Secondary outcomes were blood pressure, waist circumference, and health-related quality of life.

RESULTS: A total of 50 persons were randomized. Participants had an average BMI of 38.1 kg/m2 and were taking an average of 5.4 prescription medications; 50% were men and 25% were ethnic minority. Participants in the full subsidy and partial subsidy groups lost 5.9 and5.3 kg, equal to 5.3% and 5.1% of initial weight (p=0.71 for difference). No significant between-group differences were seen for changes in blood pressure, waist circumference, or health-related quality of life. Post-hoc analyses showed that two measures of adherence correlated with weight loss: 1) frequency of portion-controlled food use; and 2) days of food records kept.
CONCLUSION: Participants that paid for half of their food in an obesity treatment program lost a clinically

similar amount of weight (5.1%) as did participants that received all of their food for free (5.3%). As expected, individuals that were more adherent lost a greater amount of weight. These results suggest that a partial subsidy could be an effective method to lower the cost of obesity treatment, without reducing its efficacy. The estimated cost of treatment in the partial subsidy condition was less than the cost of 1 year of attending Weight Watchers. These results require replication in larger trials. If confirmed, the implications would be clear: more individuals can undergo treatment at a lower cost. Such a finding would be highly relevant, given the mandate of health care reform to provide obesity treatment to more people.

INCREASING RATES OF PSYCHOSTIMULANT-RELATED DEATHS Susan Calcaterra 1; Ingrid Binswanger1. 1University of Colorado, Aurora, Colorado . (Tracking ID # 7907)

BACKGROUND: Methamphetamine and other psychostimulants, like dextroamphetamine (Adderall) and methylphenidate (Ritalin), are highly addictive and widely abused. Their use has increased during the last decade in the United States. Little is known about psychostimulant-related death or predisposing risk factors to death. This study was designed to assess trends in psychostimulant-related deaths in the United States from 1999 to 2006. We expected that psychostimulant-related deaths would increase, paralleling the increased use reported in the 2005 National Survey on Drug Use and Health.

METHODS: We reviewed all deaths in the United States from 1999 2006 using death certificate data stored in the CDC Wonder Database. We determined the number of deaths, age-adjusted death rates (number deaths per 100,000 person years [p-y] and 95% confidence interval [CI]), age group, gender, race, state of residence upon death, and primary cause of death for all decedents with the ICD-10 code T43.6, poisoning by psychostimulants with abuse potential.

RESULTS: Psychostimulant-related deaths increased over a 7-year period. The death rate was 0.2 per 100,000 p-y (95% CI 0.2-0.3) in 1999 (n=700) and climbed to 0.7 per 100,000 p-y (95% CI 0.7-0.7) during 2005 (n=2023). There was a slight decline in the rate of psychostimulant-related deaths during 2006 (n=1848) to 0.6 per 100,000 p-y (95% CI 0.6-0.6). Those decedents aged 3544 years had the highest death rate among all age groups (1.4 per 100,000 p-y, 95%CI 1.3-1.4). The death rate related to psychostimulants abuse among men (0.9 per 100,000 p-y, 95% CI 0.9-1.0) was two times higher than among women(0.4 per 100,000, 95% CI 0.3-0.4). American Indians/Alaska Natives had the highest overall death rate (1.6 per 100,000 p-y) compared to Non Hispanic whites (0.7per 100,000 p-y, 95% CI 0.7-0.8). Psychostimulant-related deaths clustered in the Western United States. For instance, Nevadas death rate 3.6 per 100,000 p-y during 20052006. The most common primary cause of death in those who died with psychostimulants was accidental poisoning. The death rate from accidental poisoning involving psychostimulants increased from 0.2 to0.5 per 100,000 during the years 19992006. Other common primary
causes of death included mental and behavioral disorders due to the use of psychoactive substances, intentional self poisoning, and ischemic heart disease.

CONCLUSION: Psychostimulant-related deaths increased from 1999 2005 with a slight decrease in 2006, and was especially prominent in the Western U.S. Alaska Natives/American Indians are disproportionately over-represented in psychostimulant-related deaths. The most common cause of death was accidental overdose. Policy passed in 2005, the Combat Methamphetamine Act, which limited over-the-counter sales of pseudoephedrine and ephedrine, may account for the slight decrease in psychostimulant-related deaths seen in 2006. Further data are needed to assess this trend. Limitations in this study relate to the ICD-10 coding for psychostimulants which are not sufficiently sensitive to determine whether deaths were related to methamphetamine vs. pharmaceutical psychostimulants. Further interventions need to be developed to reduce the risk of death from psychostimulants.

ORAL HYDRATION AND ALKALINIZATION IS NON-INFERIOR TO INTRAVENOUS THERAPY FOR PREVENTION OF CONTRAST INDUCED NEPHROPATHY IN PATIENTS WITH CHRONIC KIDNEY DISEASE Roy Cho 1; Nosheen Javed 1; Darren Traub 1; Sobhan Kodali 2; Folefac Atem 3; Venkatraman Srinivasan4.

1Western Pennsylvania Hospital, Pittsburgh, Pennsylvania ; 2WPH, Pittsburgh, Pennsylvania ;
3UPMC, Pittsburgh, Pennsylvania . (Tracking ID # 7939)
BACKGROUND: The increased risk for contrast-induced nephropathy (CIN) in patients with chronic kidney disease (CKD) undergoing coronary angiography (CAG) has been established. Current and historical data on CIN prevention strategies have shown wide variation with respect to the optimal type, route and timing of these therapies. We hypothesize that oral hydration and/or oral sodium bicarbonate is non-inferior to intravenous hydration and/or sodium bicarbonate in the incidence of CIN in patients with CKD undergoing CAG.
METHODS: This is a prospective study randomizing patients with CKD undergoing CAG into 4 groups: 1) Intravenous normal saline, 2) Intravenous normal saline and intravenous bicarbonate, 3) oral hydration, and 4) oral hydration and oral bicarbonate. Groups 1 and 2 are defined as standard of care regimen. The primary endpoint is the occurrence of CIN defined as greater than 25% increase or absolute increase of 0.5 mg/dL in serum creatinine from baseline to 72 hours following exposure to radiocontrast. Secondary endpoints include the length of hospitalization and in-house mortality.
RESULTS: A total of 91 patients (p=0.05; power=0.8) were randomized into four treatment groups. There were no statistical differences in baseline demographics between the four groups. Baseline serum

creatinine and total contrast exposure was similar among the four groups. We found no statistical significance in incidence of CIN between our intervention strategy and standard of care regimen (p=0.617 and p=0.525).
CONCLUSION: Oral hydration was non-inferior to intravenous CIN prevention strategies in this single center study. These findings may support oral route as a novel approach in prevention of CIN in patients with CKD undergoing CAG.

IMPACT OF INTERNAL MEDICINE RESIDENT WORKLOAD AND HANDOFF TRAINING ON THE QUALITY OF CARE IN HOSPITALS Stephanie K. Mueller 1; Stephanie A. Call 2; Furman S. McDonald 3; Andrew J. Halvorsen 3; Jeffrey L. Schnipper 4; LeRoi S. Hicks1.
1Brigham and Womens Hospital, Boston, Massachusetts ; 2Virginia Commonwealth University, Richmond, Virginia ; 3Mayo Clinic, Rochester, Minnesota ; 4Brigham and Womens Hospital, Sharon, Massachusetts .
(Tracking ID # 7942)
BACKGROUND: Recent modifications to Accreditation Council for Graduate Medical Education (ACGME) duty hour restrictions have resulted in increased transitions of care by housestaff and variation of resident workload in clinical settings. In this study, we evaluated the association between resident workload, transitions of care training and evaluation, and patient outcomes.
METHODS: We linked the 2008 survey of Association of Program Directors of Internal Medicine (APDIM) to the 2008 Hospital Quality Alliance (HQA) and 2007 American Hospital Association (AHA) databases in order to assess if resident workload and training and evaluation of patient hand-offs are associated with outcomes of 30 day readmission rate and mortality rate for 3 conditions: acute myocardial infarction (AMI), congestive heart failure (CHF), and pneumonia. Predictors of interest were residency program training and evaluation of patient hand-offs (both yes vs. no) and resident workload, characterized by

reported average maximum number of patients per intern on non-call days (maximum census) and average maximum number of patients admitted per intern on call days (maximum number of admissions) during general medicine rotations. We utilized linear regression models to examine the relationship between these predictors and each study outcome, controlling for hospitals geographic location, ownership, setting (urban versus rural), nursing intensity (nurses/1000 patient days), teaching intensity (resident/beds), presence of an ICU, and insurance mix, and the residency programs board certification three-year pass rates and affiliation with a

cardiology fellowship. RESULTS: Of the 372 internal medicine residency programs surveyed, 268 (72%) responded. Of these, 180 (67%) programs reported training housestaff in conducting hand-offs and 133 (50%) programs reported evaluating housestaff in hand-offs. The mean maximum census was 11 patients on non-call days with a mean maximum of 5 patients admitted on call days. Results of the multivariate analysis demonstrated no association between hand-off training or evaluation or resident work load on readmission rates for any condition, or mortality rates for AMI or CHF. However, programs that evaluated their residents on patient hand-offs had a significantly increased adjusted pneumonia mortality rate(11.4% versus 10.8%, p=0.03) and programs that trained their residents on hand-offs had a significantly decreased adjusted pneumonia mortality rate (10.9% versus 11.8%, p=0.005) compared with programs that did not.
CONCLUSION: In this nationally-representative study of internal medicine residency training programs and their primary affiliated hospitals, we found no association between resident workload and evaluated outcomes. There were discordant findings on pneumonia mortality rates in programs that evaluate and programs that train their housestaff on patient hand-offs. Programs that evaluate their residents on care transitions have significantly higher pneumonia mortality rates than programs that do not, possibly suggesting programs with poorer outcomes are more likely to evaluate housestaff on hand-offs. Conversely, programs that provide hand-off training show significantly decreased mortality rate for pneumonia than programs that do not. This association between care transitions training and outcomes is particularly important in todays climate of further duty hour restrictions necessitating increased hand-offs. Future work must further assess the impact of care transitions on quality of care, including process measures, in order to further characterize these findings.

PHYSICIAN COMPLIANCE WITH IMMUNIZATION IN ADULTS65 YEARS OF AGE IN AN ACADEMIC SETTING: ARE WE NEGLECTING AN OZ. OF PREVENTION? Peters Okonoboh 1; L. Mary Mathew1.
1Unity Health System, Rochester, New York . (Tracking ID # 8076)

BACKGROUND: The efficacy of vaccines in the prevention of infectious diseases is well established. Despite the obvious efficacy, the national rate of immunization remains low. In 2009, the national average for pneumococcal and Influenza vaccination were 61% and 67% respectively.
METHODS: We conducted a Quality Improvement (QI) project at the Unity Faculty Practice (UFP); a resident-run, faculty supervised ambulatory longitudinal clinic experience. This is an academic practice involving 40 medicine residents supervised by 7 faculty members. We looked at the rates of recommended immunizations in patients 65 years per ACIP guidelines , i.e. Influenza, Pneumococcal, Tetanus and Zoster Vaccinations. A retrospective review of Electronic Medical Records (EMR) of eligible patients seen at the UFP was done. The study period
spanned from 20062010; information on 259 patients were retrieved and analyzed.
RESULTS: The average rate for Pnuemovax vaccination was 70.4% with a range of 36.8% - 90%, for Influenza vaccination, the average rate was53.75% (26.3% - 90%). For Tetanus vaccination the average rate was41.25% (2.5% - 85%) while for Zoster vaccine, the average rate was18.3% (7.5% - 35%).
CONCLUSION: The QI project showed a wide variation in compliance of immunizations rates among the 7 faculty members. Despite the academic setting, the rate of immunization was well below the CDC 2010 goals of 90% for both pneumococcal and influenza vaccines. This underscores the role of the teaching attendings to remind residents about the simple, inexpensive yet powerful tools of primary prevention through immunizations. The internal medicine Residency is a period where principles of prevention and their far reaching benefits need to be enforced by the faculty. The General Medicine Faculty should serve as role models in the practice of ACIP recommendations. In this day of high technology treatment that benefits an individual patient, one cannot forget the basic principles of preventive medicine that benefits large population groups.

STUDENT HEALTH REFUGEE EDUCATION COLLABORATIVE (SHREC) Crystal A Medina 1; Eva Aagaard2.
1UC Denver SOM, Denver, Colorado; 2UC Denver SOM, Aurora, Colorado. (Tracking ID # 8085)

BACKGROUND: Refugees are recognized as one of the poorest and most medically underserved populations

in Denver. Often fleeing as a direct result of conflict or persecution in their country of origin, refugees frequently endure malnutrition, physical violence, sexual assault, psychological trauma, and severe deprivation from basic necessities before they ever arrive in the United States. Implicit in these findings is the realization that refugee healthcare cannot be effective without comprehensive culturally appropriate care. The overall purpose of the Student Health Refugee Education Collaborative (SHREC) project is to perform a comprehensive assessment of the needs of the Denver Refugee population. To date, surveys and interviews with key informants and providers have been performed. However, information was still lacking on the perceptions of the refugees themselves. Our purpose was to assess refugee perception of their health and healthcare needs and the feasibility of a student-led service learning program within this population.
METHODS: Forty-five refugees participated in five focus groups from July 2009 to October 2010. Questions focused on the refugees understanding of illness, the challenges faced in the healthcare setting and in accessing necessary services, provider-patient relationships, and major cultural and environmental influences on their overall health and healthcare. Qualitative analysis via grounded theory was used to examine the data.
RESULTS: Preliminary analysis revealed several themes including difficulty with navigating the healthcare system, the need for better access to services, a lack of understanding of western medicine, and financial challenges. Many of the refugees describe not knowing how to find their way through the healthcare system as one of their primary difficulties upon transitioning to life in the US. Long waits for appointments, inadequate follow-up, scarcity of mental health services and dental care, and the eight-month expiration period of Medicaid further limit access to care. Lack of education with reference to medical issues has kept many from seeking needed care. Several refugees felt that they would not know what questions to ask or be able to

understand what the provider was telling them even with an interpreter present. These difficulties are compounded by fear of not being able to pay medical bills. Refugees consistently welcomed the idea of medical students aiding them with some of these issues.
CONCLUSION: There is a clear role for a medical student-led service learning initiative. Efforts should focus on helping refugees to better understand western medicine and the US healthcare system, including what services are available and how medical care is paid for. In addition, students can have an important role in advocating for the needs of this population with local and national government. As a next step, we will pilot a 1st and 2nd year medical student elective in which students will learn about life as a refugee. Students will also have the opportunity to teach the refugees about western medicine and the US healthcare system. The goal of the elective will be to inform medical students about the plight of refugees and ultimately, encourage future advocacy on their behalf.

A COMMUNITY BASED HEALTH ASSESSMENT OF GERIATRIC FILIPINO AMERICANS IN CHICAGO Jane Jih 1; Carmela Estrada Bondad2. 1The University of Chicago Medical Center, Chicago, Illinois; 2Filipino American Community Health Initiative of Chicago, Chicago, Illinois . (Tracking ID # 8148)
BACKGROUND: Limited studies have investigated Filipino American health, the second largest group of Asian Americans. Several analyses, particularly in California, have shown health disparities in cardiovascular disease and cancer among Filipino Americans compared to other Asian American ethnic groups and to other racial groups. Illinois has the sixth largest population of Asian Americans and Filipino Americans are the second largest Asian subgroup in Illinois, with 56,000 living in Cook County. With under developed research and resources dedicated to Asian Americans in the Midwest, there is a need to evaluate specific health needs and disparities within these underserved communities. To guide the implementation of health education interventions in the Chicago Filipino American community, a pilot health needs assessment of Filipino and Filipino American seniors was initiated.

METHODS: A convenience sample of Filipino and Filipino American individuals aged 60 years old and older who participated in weekly activities at a Filipino cultural center was invited to participate in a 30-minute face-to-face recorded semi-structured interview. Demographic information and self-reported general medical history including preventive care was collected. Participants were asked about their perceptions of health problems in their community, availability and utilization of health resources in their community, and willingness to participate in specific types of health education activities. Participants were asked to rate their perceptions on a Likert scale. The interviews were analyzed for common themes.
RESULTS: There have been 35 participants to date, mean age 72.6 years old with 28 of the 35 participants being female. Over eighty percent of the participants had health insurance in the last year and half of the participants were seeing a physician at least once every three months. Hypertension, ophthalmological disorders, arthritis, and hyperlipidemia were the most commonly self reported health problems. Heart disease, diabetes, hypertension and hyperlipidemia were most frequently cited as somewhat of a problem or a major problem in the community by the participants. Almost one third of the participants noted depression as at least somewhat of a problem in the community while only 5 participants reported a personal history of depression. Challenges locating or
utilizing health education programs and insurance coverage was most frequently cited to be at least somewhat of a problem in the community. Almost all participants were interested in engaging in at least one of the proposed health education programs.
CONCLUSION: While this study is limited by a small sample size, cardiovascular disease has emerged as a prevalent health problem in the Chicago geriatric Filipino American community. The divergence of self reported history of depression and perception of depression as a community health problem may point to generational and cultural stigma, highlighting a significant health concern that merits further investigation and action. Although most participants were insured in the last year and seeking physician services, insurance coverage was most frequently reported as a problem in the community which needs to be explored. Community based health research in the Chicago Filipino American community supports grassroots efforts to address disparities and contributes to a growing body of literature of a traditionally understudied minority group.
PROPHYLACTIC ANTICOAGULATION IS SAFE IN PATIENTS UNDERGOING FLAP RECONSTRUCTION POST MASTECTOMY: A SINGLE-CENTER SINGLE-SURGEON RETROSPECTIVE REVIEW Diwakar Davar 1; Michael L Gimbel 1; Roy E Smith1. 1University of Pittsburgh Medical Centers, Pittsburgh, Pennsylvania. (Tracking ID # 8159)
BACKGROUND: Free vascularized flap reconstruction is frequently employed in breast reconstruction after mastectomy for oncological surgery. Flap thrombosis remains a common complication occurring in approximately 5-8% of cases and often leads to flap failure. There is no consensus on the use of peri- and post-operative anticoagulation to aid in preventing thrombosis. We report the results of a single-center single-surgeon experience in which routine anti-platelet and anti-coagulation therapy peri- and post- operatively was employed for prophylaxis for flap thrombosis.
METHODS: Initially the surgeon used no anti-platelet and anticoagulation therapy. Starting in late 2007, he started using routine peri- and post- operative anticoagulation. We retrospectively surveyed 103 patients who were operated on between 2006 and 2010. Patient details were obtained from the electronic record using the Current Procedural Terminology (CPT) billing codes for free flap breast reconstruction. Pertinent details were abstracted from the medical record.
RESULTS: Pre-operatively 40(44%) received prophylactic LMWH whilst 50(56%) did not. Post-operatively, 64(71%) received prophylaxis with either LMWH and/or aspirin whilst 26(29%) did not. No vessel thromboses were noted post-operatively. 2 patients had hematoma formation and 2 had major bleeding necessitating transfusion. Routine anti-coagulation (defined as either LMWH and/or aspirin use) was not associated with an increased incidence of bleeding events (p=0.62, Fishers exact test).

CONCLUSION: Flap thrombosis remains a complication with devastating consequences and prevention of thrombosis requires many factors -including the judicious use of anticoagulation. We conclude that the routine use of peri- and post- operative anticoagulation with either LMWH and/or aspirin is not associated with an increased incidence of bleeding complications post-operatively and is safe.
This study was not powered to statistically prove that anticoagulation in this setting prevents flap thrombosis. A prospective randomized trial to investigate this would greatly aid in defining the optimal anti-coagulation strategy in this group of patients.
S10 ABSTRACTS JGIM
DEMENTIA SCREENING IN PRIMARY CARE Becky J. Brott 1; Janet S Cellar 1; James J Lah1. 1Emory University School of Medicine, Atlanta, Georgia. (Tracking ID # 8170)
BACKGROUND: The population over age 65 is expected to double by 2030, and the prevalence of dementia will nearly triple. Diagnosing dementia by self-reported symptoms often leads to delayed and missed diagnoses. Therefore dementia screening is essential. With a declining pool of certified geriatricians to care for the growing aging population, primary care physicians (PCPs) will be increasingly called upon to diagnose dementia. The purpose of this research is to determine the rate of dementia screening and diagnosis in patients over 65 in an academic primary care clinic.
METHODS: Records of 203 patients attending a university based primary care clinic in a one month period were examined, and charts of the 49 patients over 65 were reviewed. Abstracted data included patient and caregiver characteristics, problem list, memory loss symptoms, suspicion for dementia, and dementia evaluation including screening, neuropsychological testing, specialist referral, diagnosis, and treatment. Screening tests included the Mini-Cog, Functional Activities Questionnaire (FAQ), MMSE, Clocks, and Geriatric Depression Scale (GDS). RESULTS: Mean patient age was 72 + / - 5.6, and 33 (67%) were female. None of the patients were screened for dementia. Memory loss symptoms were recorded in 11 patients (22%), 10 (20%) had suspicion of dementia, 6 (12%) were referred for neuropsychologic testing, and 8 (16%) were referred for specialists evaluation. Dementia was diagnosed by specialists in 3 patients (6%), and 1 received pharmacologic treatment. The length of the problem list correlated to symptoms of memory loss. Problem lists ranged from 116 problems, mean 4.5 + / - 2.9. Linear regression found each additional problem increased the chance memory loss symptoms by 3.9%.
CONCLUSION: None of the patients received dementia screening or diagnosis from their PCP. Ultimately, 6% were diagnosed by specialists, well below half of the estimated prevalence. The reason for lack of screening is unclear, but the lower than expected rates of diagnosis may be due to symptoms of memory loss appearing as problem lists lengthen. Without knowledge of a quick screening tool, problem list burnout likely contributes to the lack of screening and diagnosis in complex medical patients. After expanding this baseline data set, an educational intervention is planned to introduce a simple screening tool, the Mini-Cog/FAQ, and assess its impact on screening and diagnostic behaviors.
EDUCATING UNDERSERVED PATIENTS ABOUT COLORECTAL CANCER SCREENING: MULTIMEDIA VS PRINT Gregory Makoul 1;
Denise Scholtens 2; Ashley Negrini 1; Kenzie A Cameron 2; Jason Thompson 2; Adam Williams 2; David Baker2. 1Saint Francis Hospital and Medical Center, Hartford, Connecticut; 2Northwestern University Feinberg School of Medicine, Chicago, Illinois. (Tracking ID # 8326)
BACKGROUND: Colorectal cancer (CRC) is one of the most common types of cancer in the United States. Despite strong evidence and recommendations supporting CRC screening, screening rates remain low. This study focuses on comparing message-equivalent patient education programs (multimedia vs print) designed to provide patients with understandable information and motivational messages about CRC screening. Primary questions: Do messages have a different impact on knowledge and/or screening behavior when delivered by multimedia or print? Does literacy level affect response? Based on our review of the literature, we believe this

study is the first to explicitly compare the effects of message-equivalent print and multimedia materials.
METHODS: In this randomized controlled trial, patients 5080 years of age at the time of their clinic visit are assigned to one of three study arms: (1) Control/usual care; (2) Multimedia; (3) Print. The multimedia program incorporates illustrations, animations, photographs, and voice-over. Using the multimedia program as our starting point, we reverse-engineered a print version to yield materials with the same text and graphics. Lexile analysis indicates that the text is geared to a 4th
grade reading level; there are English and Spanish versions of both interventions. Study sites are 3 Midwest clinics for the poor and underserved. After engaging in an IRB-approved consent process with a bilingual RA, patients engage in a structured interview, view the randomly assigned intervention, and complete a literacy assessment (S-TOFHLA). Immediately after their doctor visit, patients have a brief follow-up encounter with the RA and receive a $10 gift card. Completion of CRC screening within 3 months of the index visit is determined using the clinic registry. If there is no record of screening completion, RAs attempt to ascertain reasons by calling patients approximately 100 days after the index visit.
RESULTS: This report includes data collected for 690 patients. Mean age was 57.7 (SD=6.4), 68% of the patients were female, 58% self-identified as Hispanic/Latino, and 53% of the surveys were conducted in Spanish. Nearly half (46%) of the patients had 8th grade education or less; 35% had inadequate health literacy. Print and multimedia interventions both led to marked increases in knowledge regarding polyp, colon, stool cards and colonoscopy. While there was very little difference in evaluation of the interventions by the adequate literacy group, subjects in the inadequate literacy group found the multimedia program more informative, believable, interesting, and understandable ($p<.05$ for each). In terms of actual screening, completion rates are low across all three arms of the study. Telephone follow-up with 241 of the patients who did not get screened provides insight: The doctor did not recommend it was the overwhelming reason for not getting screened, mentioned by 61% of the patients.
CONCLUSION: The print and multimedia interventions in this study optimize message design and include parallel content to allow direct comparison. Data collected to date indicate that, despite the demonstrated quality of both interventions across literacy levels, physician recommendation is the most powerful vector for patient uptake of CRC screening. While physicians at the study sites are periodically reminded to talk with patients about CRC screening, more robust physician-directed interventions are required to achieve the ultimate goal of markedly increasing CRC screening.
CHARACTERISTICS OF CHRONIC KIDNEY DISEASE (CKD) PATIENTS WITH DIABETES WHO HAVE CKD NOTED IN THEIR PROBLEM LIST IN A LARGE ELECTRONIC HEALTH RECORD BASED CKD REGISTRY: A CALL TO ACTION Stacey Jolly 1; Sankar
Navaneethan 1; Jesse Schold 1; Susana Arrigain 1; Welf Saupe 1; John Sharp 1; Anil Jain 1; Martin Schreiber 1; James Simon 1; Joseph Nally1.
1Cleveland Clinic, Cleveland, Ohio. (Tracking ID # 8410)
BACKGROUND: Chronic Kidney Disease (CKD) is a growing public health problem. We developed a CKD registry from our electronic health record (EHR) at Cleveland Clinic to create programs to improve CKD management including quality of care guidelines for Diabetes Mellitus (DM). We aimed to examine if differences existed in demographics and processes of care measures among DM patients with CKD based on whether CKD was listed in their EHR problem list. The problem list is readily available in the EHR, shown during each patient encounter, maintained by providers, and has been linked to information technology tools to improve patient care in our health system.

METHODS: Patients entered the registry by having two outpatient eGFRs <60 ml/min/1.73 m2 (MDRD

equation) at least 90 days apart from Jan 2005 to Oct 2010. We examined a subgroup of patients who had DM and were followed for at least a year. DM was defined by having two separate DM related ICD-9 codes noted during outpatient visits prior to or at date of entry into the registry. CKD was noted in the patients EHR problem list if CKD (defined by ICD-9 codes) was present within 1 year after date of entry into the registry. We calculated the proportion of CKD patients with DM who had CKD noted in their problem list and examined if differences in age, sex, race, insurance, eGFR at time of entry; nephrology visit and CKD labs, or medications prescribed differed between the two groups.
RESULTS: Of the 55,000 patients in our CKD registry, 8711 (16%) had DM and been followed for at least a year. 782 (9%) had CKD noted in the EHR problem list. They were younger (66 vs 70 yrs) and more likely to have a low eGFR (<45) at time of entry (79% vs 33%). Table 1 shows additional differences found between the two groups.
CONCLUSION: Among CKD registry patients with DM, failure to include CKD in the EHR problem list was highly variable based on patient characteristics and was associated with less nephrology visits and CKD laboratory measures checked and inappropriate medication use. Targeting awareness and using the EHR problem list with novel interventions may improve CKD outcomes in the clinical setting.
PHYSICIANS ON TWITTER Katherine Chretien 1; Justin Azar 2; Terry Kind3. 1George Washington University; Washington DC VA Medical Center, Washington, District of Columbia ; 2George Washington University, Washington, District of Columbia ; 3Childrens National Medical Center, Washington, District of Columbia .
(Tracking ID # 8414)
BACKGROUND: Social media is transforming the way physicians communicate with the public, bringing both challenges and opportunities for medical professionalism. Hospitals, public health departments, and other medical institutions have started to use the popular social networking and micro-blogging site Twitter as a marketing tool and a way of disseminating health information. Physicians may use Twitter to extend their web presence, communicate with patients, market themselves, or informally interact with colleagues. Yet, it is unknown how physicians are using Twitter as a communication tool. The objective of this study was to describe the characteristics of self-identified physicians on Twitter and how they use Twitter, with a specific focus on professionalism.
METHODS: Descriptive characteristics were extracted from the public profile pages of self-identified physicians with 500 or more followers on Twitter in May, 2010. Content analysis of 5156 of their postings (tweets) was performed (the last 20 available tweets at time of data extraction for each Twitter user, excluding non-English tweets). Main outcome measures included: percent of physician profiles with full name, photograph, specialty, and/or geographic location on profile; percent of tweets that were health/medical, contained a hyperlink, were personal communications or re-tweets; recommended or criticized a medical product; were self-promotional; were related to medical education; contained potential patient privacy violations, profanity, sexually explicit material, discriminatory, or other unprofessional material. Three authors pilot-coded tweets together, and through an iterative cycle, refined the coding guide until kappa >0.78 for all categories or inter-rater agreement=100% was attained. The three authors subsequently coded tweets independently, with regular team discussions. All potentially unprofessional tweets were reviewed by the entire team for consensus.
RESULTS: Of the 260 users identified, most were identified by full name (78%) and photograph (78%). 240 (92%) profiles linked to websites. Surgery (15%) and internal medicine (11%) were the most prevalent specialties represented. Of the 5156 tweets analyzed, 49% (2543) were health/medical, 21% (1082) were personal communications, 14% (703) were re-tweets, and 58% (2965) contained links. Seventy-three tweets (1%) recommended a medical product or proprietary service, 634 (12%) were self-promotional, and 31 (1%) were related to medical education. 144 (3%) were categorized as unprofessional. 38 (0.7%) tweets represented potential patient privacy violations, 33 (0.6%) contained profanity, 14 (0.3%) included sexually explicit material, and 4 (0.1%) included discriminatory statements. 55 (1%) tweets were coded other unprofessional, including 12

possible conflicts of interest, such as making unsupported claims about a product they were selling on their website or repeatedly promoting specific health products, and 10 statements about medical therapies that were counter to existing medical knowledge and guidelines.
CONCLUSION: Self-identified physicians on Twitter share medical information with the public. Ethical breaches and unprofessional content were observed. Greater education, guidelines, and accountability for health professionals are needed to maximize societal and professional benefit through engagement with social media.
IMPROVING PATIENT UNDERSTANDING OF THE DISCHARGE PLAN BY IMPLEMENTING A NEW PATIENT-CENTERED DISCHARGE PROCESS ON AN ACADEMIC SERVICE Jimmy Daniel Fernandez 1; Jennifer Caceres, MD2. 1University of Miami, Coral Gables, Florida;
2University of Miami at JFK, Atlantis, Florida. (Tracking ID # 8431)
BACKGROUND: According to a study funded by the Agency for Healthcare Research and Quality, patients are 30% less likely to be readmitted or visit the emergency department if they have a clear understanding of their discharge instructions. Despite the importance of the discharge process, very few medical residency training programs offer formal discharge planning education. We hypothesize that introducing a new discharge order form that is completed by a medical resident and reviewed with each patient as part of the discharge process will improve patients understanding of the discharge plan.
METHODS: All patients who were discharged over a 4-week period from the academic service at John F. Kennedy Medical Center were called within one week of discharge and asked if they knew their diagnosis at discharge, were clear on medications to administer, knew the side effects of any new medications, who to call with any concerns, and if a follow up appointment was made with a primary care physician prior to discharge. A new patient-centered discharge order form as part of the discharge process was introduced after the survey was completed. Medical residents were trained how to use the discharge order form during orientation to the inpatient rotation. The discharge form required a medical resident to complete and discuss each component with the patient and obtain a signature from the patient acknowledging the discussion before the order could be executed by the nursing staff. Four months after the new discharge process was implemented, the same survey was conducted over a 4-week period. Proportions before and after the intervention were compared using chi-square tests for independence.
RESULTS: Eighty-six patients were surveyed before and after the intervention (total n=172). 52.3% versus 68.6% knew their diagnosis pre-intervention and post-intervention respectively (p=0.0290). For the proportion of patients who knew what medications to take, 77.9%

versus 74.4% answered yes pre-intervention and post-intervention respectively (p=0.5914). For the proportion of patients who knew side effects of medications, 17.4% answered favorably before the intervention compared with 46.5% after the intervention (p=0.0001). For the proportion of patients who knew who to call after discharge, there was an increase from 20.9% to 45.4% after implementation of the new discharge form (p=0.0007). For the proportion of patients who had primary care physician appointments scheduled prior to discharge, there was an improvement from 41.9% to 57.0% (p=0.0474). CONCLUSION: Implementation of a new discharge order form as part of the discharge process allows medical residents to improve patients understanding of the discharge plan. There were statistically significant improvements in the following areas: knowledge of their diagnosis, side effects of medications, who to call after discharge, and appointments scheduled with a primary care physician prior to discharge.
EFFECTS OF SMOKING CESSATION AND WEIGHT CHANGE ON CARDIOVASCULAR DISEASE AMONG PEOPLE WITH AND WITHOUT DIABETES Carole Clair 1; Nancy A. Rigotti 2; Peter Shrader 1; Caroline 1; Michael S. Fox Pencina 3; James Meigs4. 1Massachusetts General Hospital, Boston, Massachusetts ;

4General Medicine Division, Massachusetts General Hospital, Boston, Massachusetts . (Tracking ID # 8487)
BACKGROUND: Smoking cessation substantially reduces the risks of cardiovascular disease (CVD) associated with smoking among people with and without diabetes. Weight gain that follows quitting smoking may weaken the benefit of quitting on CVD risk. We have tested this hypothesis in this study.
METHODS: Among participants of the Framingham Offspring Study who were free of CVD at each baseline, we estimated 4-year risk of CVD. At each 4-year exam, self-reported smoking status (non smoking, former smoking, current smoking) was verified, diabetes (defined as fasting plasma glucose >=7 mmol/l or being on diabetes treatment) was screened and body-weight and height were measured; we calculated change in weight and in body-mass index (BMI) from the previous exam. We used three pooled logistic regression models to estimate the 4-year risk of CVD associated with smoking and diabetes status at each baseline. Model 1 adjusted for age and sex; model 2 added confounders (BMI, alcohol consumption, family history of diabetes, systolic blood pressure, HDL-cholesterol, LDL-cholesterol, triglycerides, use of anti-hypertensive or lipid-lowering medication), and model 3 added change in BMI concomitant with change in smoking status to assess its potential mediating effect on CVD. Significance was p<0.05. RESULTS: 3,142 subjects (mean age, 44 years; 52% female) were followed over 6 exams, about every 4 year, for a mean of 25 years, contributing 17,875 person-exams. Smoking prevalence decreased from 37% at the first baseline exam to 13% at the last baseline exam. Age- and sex- adjusted 4-year incidence rates of CVD were higher among smokers vs. former smokers or non smokers in people with and without diabetes (Figure 1). On average, 4-year weight gain was lower in smokers vs. non smokers (1.21 kg vs. 1.46 kg, p=0.02) whereas it was similar between former smokers and non smokers(1.45 kg vs. 1.46 kg, p=0.16). In multivariable-adjusted analysis, smokers had higher risks of developing CVD than non smokers whether or not they had diabetes. Former smokers did not have a significantly higher risk of developing CVD than non-smokers, although significant trends across smoking categories, both among people with diabetes (P=0.02) and those without diabetes (P<0.0001) suggested a dose response phenomenon. Adjusting for change in BMI did not decrease the risk estimates, suggesting that post-cessation weight change does not mediate the increase risk of CVD among both people with and without diabetes (Table 1).
CONCLUSION: Post-cessation weight gain does not alter the benefits of quitting smoking on CVD risk in people with and without diabetes.

DO PHYSICIANS WANT THE PATIENT-CENTERED MEDICAL HOME? Temple Howell-Stampley 1; Lynne Kirk 1; Kim Batchelor 1; Ethan Halm2.

1UT Southwestern, Dallas, Texas; 2Univ. of Texas Southwestern Medical Center, Dallas, Dallas, Texas .

(Tracking ID # 8513)

BACKGROUND: The patient-centered medical home model (PCMH) holds great promise to improve the delivery of health care. One of the many unanswered questions about the PCMH is whether physicians will accept the model. We asked physicians to identify changes they thought would improve the patient care they provide. We compared the suggested changes to the standards for the PCMH.

METHODS: We administered a 3 round iterative questionnaire to 31 faculty members practicing in an academic GIM clinic. The physicians were asked: 1) What do you do for your patients in clinic now that could be done better by someone else? 2) What do you wish could be done for your patients that is not being done now? 3) What would you like to have more time to do for your patients? 4) What information and resources would be helpful for you to care for individual patients and for your population of patients? They rated and then ranked the items generated. We received responses from 24 physicians totaling 135 items. These were sorted into 8 categories and similar items were combined into 71 items. For round 2, the physicians rated each item on a 5 point Likert scale. Those with a score of >3.2 were listed in order of their rating, resulting in 55 items. These items were independently matched by 2 of the investigators (T H-S, LK) to the National Committee for Quality

Assurance (NCQA) Physician Patient Connection (PPC) standards for recognizing medical homes. If the 2 reviewers differed on whether an item met a standard, the other investigators resolved it. For Round 3, the 55 items were combined into 26 items in 2 categories. The physicians had the opportunity to rank-order the items and include any that had been excluded by rating score.
RESULTS: Of the 55 items in the list for round 2, 46 matched a specific PPC standard. Of the remaining 9, all were matched to a PCMH principle, i.e. patient-centered, coordination of care, etc. There were no physician-generated items that did not match to a principle or standard of the PCMH. The final list included 20 items that the physicians felt should be done for their patients by others and 6 items that physicians want more time to do for their patients.
CONCLUSION: The vast majority of physician-generated ideas on how to improve care in a GIM practice match the NCQA criteria for
recognition as a PCMH. The process of letting physicians identify ways to improve practice a priori may facilitate the changes required for the development of a PCMH.
EVALUATION OF A PILOT HOSPITALIST PROGRAM AT AN ACADEMIC AFFILIATED VA HOSPITAL: IMPACT ON PATIENT OUTCOMES AND TEACHING Christine Michelle Perry 1; Simone Kanter 1; Manjulika Woytowitz 2; Tina Bronner 3; Alexander Cheung 3; Michal Hose 3; Peter Cadman3. 1Va HCS SD, La Jolla, California ; 2VA HCS SD, La Jolla, California ; 3Va HSC SD, La Jolla, California . (Tracking ID # 8523)
BACKGROUND: Literature has emerged indicating potential benefits from separating inpatient and outpatient care between collaborating groups of internists, hospitalists and non-hospitalists. In teaching hospitals that lack hospitalist systems for inpatient care, academic physicians who do little inpatient care and teaching may be conscripted for these activities for several weeks a year. Our work group evaluated whether there was a difference in inpatient outcomes and faculty teaching evaluations between a pilot hospitalist team (Pilot) and traditional attending model (Trad).
METHODS: Patients admitted to the medicine service at the VA San Diego Health Care System (VASDHS) are cared for by clinicians who spend the majority of their time in the outpatient setting. Four General Internal Medicine physicians volunteered for a pilot hospitalist program, with an increased percentage of time devoted to inpatient duties (25%). They rotated in 2-week periods covering a hospitalist ward team. While not on wards these physicians continued to engage in outpatient care for their established primary care panels. The Trad includes 3 inpatient teams of other internal medicine faculty rotating in 3.5-week long blocks. We extracted the following variables from the VA computerized patient record system: primary diagnosis, discharge diagnosis, admission date/ time, discharge date/ time and length of stay. Variables were grouped by assignment of patients to Pilot or Trad physicians and compared using student t-tests for continuous data and chi-square for ordinal data. We compared the inpatient teaching evaluations (Likert scale) from third year students and internal medicine residents from the University of California, San Diego (UCSD) School of Medicine during the first 12 months of the pilot program, using the Kruskal-Wallis equality of populations rank test for ordinal data and student t-test for resident data.
RESULTS: There was no significant difference in length of stay by group: Pilot team patients 4.5 days+/7.2 days and Trad team patients4.4 days+/5.4 days (p=.7). Readmission rates within 30 days did not vary, with 28/1224 (2.3%) of patients readmitted from the Trad team and 3/283 (1.1%) readmitted from the Pilot group (p = .19). There was no significant difference in patient outcomes between the Pilot and Trad. Teaching evaluations were significantly higher for the Pilot than Trad for both students and residents (p<.001)
CONCLUSION: A pilot hospitalist system was associated with improved ratings of both inpatient medical student and resident teaching. A potential explanation for these findings may be that the physicians in the pilot hospitalist group self selected to engage in those activities in which they excel. In this study, patient outcomes did not improve during the first year of a Pilot team compared to the Trad team. Benefit to many patient outcomes has been previously reported with hospitalist programs; many factors could account for failure to

observe such benefits here. Whether advantages of this approach will be sustained, and/or magnified with time is a matter for ongoing study.

GAPS IN THE MANAGEMENT OF POSTHERPETIC NEURALGIA IN THE ELDERLY POPULATION: THE BASIK PHN SURVEY Gregory D Salinas 1; P Holder Nevins 1; Terry A. Glauser 1; Mark S. Wallace 2; J. Chad Williamson1. 1CE Outcomes, LLC, Birmingham, Alabama; 2University of California San Diego, La Jolla, California. (Tracking ID # 8527)

BACKGROUND: Postherpetic neuralgia (PHN) is continued pain due to herpes zoster for >3 months after resolution of the dermatomal rash. While annual incidence of PHN in the United States is 100,000-180,000, there is a lack of published information regarding the knowledge, attitudes, and practice patterns of US physicians on their management of PHN.

METHODS: To identify needs of physicians managing patients with PHN, we distributed a case-vignette survey (BASIK PHN: Behaviors, Attitudes, Skills, Identified gaps and Knowledge of Postherpetic Neuralgia) to a nationally representative sample of US-practicing primary care physicians (PCPs) and neurologists. The total sample included 150 PCPs and 76 neurologists. The survey presented case vignettes representing typical patients with PHN to assess how the patient would be managed. Additional questions assessed side effect management, adherence, monitoring, and barriers to optimal patient care. One component of the study addressed the management of an elderly patient with a 5-year history of PHN and previous negative experiences with gabapentin, amitriptyline, and acetaminophen with codeine.

RESULTS: The majority of physicians chose multiple agents; most commonly used combinations were pregabalin/lidocaine patch, duloxetine/lidocaine patch, or pregabalin/duloxetine. Nearly half of PCPs would refer this patient to a neurologist or pain specialist. If the patient developed additional side effects from this medication, the majority of neurologists would switch to a different class of drugs and PCPs would refer. To manage adherence, PCPs were more likely to prefer weekly visits until the pain is controlled (p=.048), while neurologists had differing approaches (weekly visits, family accompaniment, diary). Major barriers to managing patients with PHN include patients high expectations about the level of pain relief and dose-limiting side effects.

CONCLUSION: This study highlights physician uncertainty regarding management of continued PHN in a patient with prior experience with multiple agents. Support regarding available resources and current best practices of side effect management may be useful to the practicing clinician.

THE HEALTH OF SAFETY-NET HOSPITALS AFTER MASSACHUSETTS HEALTHCARE REFORM: CHANGES IN VOLUME, REVENUE AND OPERATING MARGINS FROM 2006 TO 2009 Arun Mohan 1; Jennifer Grant 2; Maren Batalden 3; Danny McCormick3. 1Emory University School of Medicine, Atlanta, Georgia; 2Rollins School of Public Health, Atlanta, Georgia; 3Cambridge Health Alliance and Harvard Medical School, Cambridge, Massachusetts. (Tracking ID # 8579)

BACKGROUND: Prior to Massachusetts health care reform many uninsured, poor and minority patients were cared for primarily in safety net hospitals (SNH). A key element of the reform altered the financing of care for vulnerable populations by shifting government payments from safety net hospitals toward financing new subsidized private insurance for low-income residents. Little is known, however, about the impact of the reform on the use and financial performance of safety-net hospitals. Such knowledge
could help inform implementation of the Patient Protection and Affordable Care Act which is closely modeled on the Massachusetts reform.

METHODS: We used data from the Massachusetts Department of Healthcare Finance and Policy to assess the potential impact of the Massachusetts healthcare reform on changes in volume, revenue, and operating margins at SNH (n=7), pre (2006) and post (2009) reform and contrasted this with contemporaneous changes seen

among the 58 non-safety net hospitals (NSNH). We defined SNH as those with a high level of utilization by patients with Medicaid (>1 SD above the mean) and a low-level of utilization by patients with commercial insurance (<1 SD below the mean). For each outcome measure we calculated the mean percentage change at SNH and NSNH from 2006 to 2009. We then estimated the absolute difference (and 95% confidence intervals) in changes between SNH and NSNH over this time, often referred to as a difference-in-differences [DD] analysis, using the students t-test. Estimates for DD for operating margins and revenue per inpatient discharge and outpatient visit were weighted to hospital volume. Analyses using alternative definitions of SNH yielded similar results.
RESULTS: Outpatient revenue per visit declined 9.0% at SNH and increased 23.7%; at NSNH for a DD of -$174; (95% CI, -$281 to 66, p=.004), indicating a reduction at SNH compared with NSNH. Inpatient revenue per discharge declined 10.0% at SNH and increased 20.7%; at NSNH (DD=$1,050 [95% CI, -$1,455 to 644, p<.0001]) and operating margins declined 3.5% at SNH and increased 0.8%; at NSNH (DD=4.27%; 95% CI, -6.0% to 2.5%, p<.001)., There were also substantial, but not statistically significant differences for inpatient discharges (2.3% decline at SNH vs. 3.5% increase at SNSH; DD=598 [95% CI, -1,559-363, p=.22]), outpatient visits (14.7% increase vs1.6% increase; DD=45,343 [95% CI, -23,640-114,325, p=.16]), inpatient revenue (2.6% increase vs. 7.7% increase; DD=$17.0 million [95% CI, -47.9 million 14.0 million , p=.27]) and outpatient revenue (4.4% increase vs. 25.6% increase; DD=$22.3 million [95% CI, -63.4 million 18.8 million, p=.28]).We also found that in 2009, patients receiving Medicaid, self-pay, and other government insurance accounted for 40.8% of all discharges at SNH and 19.1% at NSNH, while they represented 53.4% of outpatient visits at SNH and21.8% at NSNH.
CONCLUSION: While SNH in Massachusetts continue to play a disproportionately large role in caring for disadvantaged patients, their financial performance has declined appreciably after implementation of Massachusetts health care reform compared with NSNH. If poorer financial performance lessens SNH capacity to care for vulnerable patients, this and similar reform efforts could have effects opposite to those intended.
WHITE COAT CEREMONIES: APPRECIATING THEIR FORMS AND MESSAGES Thomas Inui 1; Orit Karnieli-Miller 2; Richard Frankel3.
1Regenstrief Institute, Indiana University School of Medicine, Indianapolis, Indiana ; 2University of Haifa, Haifa, N/A ; 3Indiana University School of Medicine, Indianapolis, Indiana . (Tracking ID # 8630)
BACKGROUND: White Coat Ceremonies (WCCs) are prevalent in North America and elsewhere as a celebration of matriculation into medical school. Critics of WCCs have questioned whether these ceremonies can successfully combine professionalism and humanism elements, the appropriateness of the white coat (WC) as a symbol, and the meaningfulness of oaths of commitment early in the educational

process. We sought to explore the merits of these critiques in an empirical study of WCC forms and content.
METHODS: We developed a stratified random sample of 25 US schools of medicine conducting WCCs in 2009. On request, schools submitted written WCC programs (18), audio recordings (13), videos (4) and one written transcript. A qualitative approach including triangulating different analysis methods was used to discern the core meanings expressed in these ceremonies. The analysis processes included: content analysis of artifacts (e.g., program, photos, written materials, music); semantic analysis focused on words and phrases; content analysis focused on sentences and statements within the ceremonies (specifically statements about obligations and privileges, the meaning of WCCs, the white coat, and oaths); and narrative analysis focused on the stories recounted in the WCCs.
RESULTS: Although all ceremonies followed the same general form (formal ceremony protocol, keynote, 25 other speakers, cloaking, oath recitation), their content, messages and atmosphere varied significantly, often strongly expressing a schools mission and traditions. Ceremonies included five principal descriptions of what the WC symbolizes (commitment to humanistic professional care, a reminder of obligations and privileges,

power, students need to grow into their WC, and the WC as a mantle). Statements about obligations were three times more frequent than statements about privileges. Semantic analysis focused on 46 words and/ or phrases used frequently during the ceremonies (1472 utterances), which we mapped onto four consensus domainsprofessionalism (1104), humanism (663), morality (642) and spirituality (277). Sixteen different oaths were used in the 18 schools. All focused on dedication, commitment and responsibility, either as physicians-to-be or as students. CONCLUSION: Analysis of WCCs revealed these ceremonies to be neither about elitism nor guild status, but an occasion marking the beginning of educational, personal and professional formation processes. The ceremonies urged matriculants to become physicians worthy of trust. They centered on the person in a vocation; affirming its calling and obligations, donning a symbolic garb, joining an ancient and modern tradition of healing and immersing oneself in the traditions of a community. The articulated construct of the white coat in the WCCs situated it as a suitable symbol of humanism. The messages of the professional oaths, while encountered early in a students education, still might set the stage for mindfully grappling with challenging experiences later. We conclude that WCCs embody the longer traditions of medicine as a helping profession and communicate the importance of deserving trust over having privilege. As such they are more to be commended than criticized.

FOOD INSECURITY AND BODY MASS INDEX ARE ASSOCIATED IN YOUNG ADULT WOMEN Holly Catherine Gooding1; Courtney K Walls2; Tracy K Richmond2. 1Brigham and Womens Hospital and Childrens Hospital Boston, Boston, Massachusetts ; 2Childrens Hospital Boston, Boston, Massachusetts . (Tracking ID # 8653)

BACKGROUND: Food insecurity, defined by the United States Department of Agriculture as lack of access by all people at all times to enough nutritious food for an active, healthy life, is hypothesized to contribute to numerous health problems, including obesity. Food insecurity has been associated with an increase in weight in children

and adults, although results have been inconsistent. This study sought to identify whether food insecurity was associated with an increase in body mass index (BMI) in young adults and whether this association differed by gender or was modified by food stamp use or the presence of children in the home.

METHODS: Cross-sectional data from Wave 4 (20072008) of the National Longitudinal Study of Adolescent Health were analyzed. Survey sampling weights were applied to account for the unequal likelihood of certain subpopulations being sampled. Multiple linear regression was used to investigate the association between food insecurity and BMI in gender stratified models of young adult women (n=7279) and men (n=6804) ages 2432, controlling for age, race/ethnicity, income, education, physical activity, smoking, and alcohol use. Interaction terms were created to assess for effect modification by food stamp use or the presence of children in the home on the relationship between food insecurity and BMI.

RESULTS: Food insecurity was significantly more common in young adult women (14%) than young adult men (10%) ($p<0.001$) and in African Americans (19%) and American Indians (22%) compared to whites (11%) ($p<0.001$). Food insecure participants earned on average $28,500 less than those who were food secure and were more likely to report receipt of food stamps or public assistance. Individuals who reported food insecurity were significantly more likely to be current smokers ($p<0.001$) but less likely to consume alcohol ($p<0.001$), participate in physical activity ($p<0.05$), or have completed college ($p<0.001$) compared to those who did not report food insecurity. After controlling for these covariates, food insecure women had BMIs that were on average 0.9 kg/m2 units higher than women who were food secure. This result persisted after controlling for food stamp use in either young adulthood or adolescence. There was no effect modification by food stamp use, parenting children in the home, race/ethnicity, or income on the association between food insecurity and BMI. No relationship was found between food insecurity and BMI in young adult men.

CONCLUSION: Food insecurity is associated with increased BMI in a nationally representative sample of young adult women after controlling for age, race/ethnicity, education, income, physical activity, smoking, and alcohol

use. Food insecurity is not associated with BMI in young adult men. The relationship between food insecurity and BMI is not attenuated nor modified by food stamp use or the presence of children in the household. Providers should inquire about food insecurity, especially when treating young obese females and policy initiatives should address the role of access to healthy food in addressing food insecurity.

PREVALENCE OF RESISTANT HYPERTENSION IN THE UNITED STATES 20032008 Stephen Persell 1; Stephen Persell2. 1Northwestern University, Chicago, Illinois; Northwestern University, Evanston, Illinois. (Tracking ID # 8654)

BACKGROUND: Resistant hypertension has been defined as blood pressure that remains above goal in spite of the concomitant use of antihypertensive medications from 3 or more drug classes or who require 4 or more drug classes to reach blood pressure targets. This designation has been suggested in order to identify a high risk group for whom special diagnostic investigations or therapeutic considerations should be considered. The prevalence of resistant hypertension is unknown, but it is thought to be common.

METHODS: Data from the National Health and Nutrition Examination Survey from 2003 through 2008 were used. Non-pregnant examination participants at least 18 years of age were included. Blood pressures were measured according to a standardized protocol. For most participants, three measurements were taken and the mean of the second and third readings was used as the average. Participants with no recorded blood pressures were excluded. Participants were considered to have hyper-tension if the average blood pressure was >140/90 mm Hg (either systolic or diastolic), or they reported currently taking prescribed medication for hypertension. Blood pressure was considered uncontrolled if the average was >140/90 mm Hg (either systolic or diastolic). Medications were reviewed during home interviews and pill bottles were examined in most cases. Participants were classified as having resistant hypertension if their blood pressure was >140/90 mm Hg and they reported using antihypertensive medications from 3 different drug classes in the past month or drugs from 4 or more antihypertensive drug classes regardless of blood pressure. Drug classes included: ACE inhibitors, ARBs, beta-blockers, dihydropyridine calcium channel blockers, non-dihydropyridine calcium channel blockers, thiazide-like diuretics, loop diuretics, potassium-sparing diuretics, peripheral alpha-adrenergic receptor antagonists, central-acting and other anti-adrenergic drugs, direct vasodilators, and direct renin inhibitors. Participants with resistant hypertension were compared to drug treated participants who were controlled receiving 3 or fewer drug classes or who were uncontrolled using 2 or fewer drug classes. Analyses used weights that account for the probability of selection, and non-response. SAS survey commands to account for the complex multistage sampling design and provide accurate standard errors and tests of significance were used to produce descriptive statistics and comparisons between groups.

RESULTS: Among U.S. adults with hypertension, 8.9 percent (standard error, SE 0.6) met these criteria for resistant hypertension. This represented 12.9% (SE 1.1) of the antihypertensive-drug-treated population. Among all uncontrolled drug-treated adults, 72.4% (SE1.6) were taking drugs from fewer than 3 classes. Compared to those with controlled hypertension using 1 to 3 medication classes, adults with resistant hypertension were more likely to be older, to be non-Hispanic black, and to have higher mean body mass index (all p They were also more likely to have: micro and macro albuminuria, an estimated GFR of less than 60 ml/min, and self reported medical history of coronary heart disease, heart failure, stroke and diabetes mellitus (uncontrolled hypertension using 2 or fewer drug classes were similar. Most adults with resistant hypertension used a diuretic85.6% (SE 2.4). However of this group, 64.4% (SE 3.2) used the relatively weak thiazide diuretic hydrochlorothiazide. The study has several limitations. There is no information concerning dosage (sub-optimal doses may have been used) or adherence (some medications may have been used in the past month but not regularly). Therefore the proportion with truly resistant hypertension may be lower than what was observed.

Conversely, some uncontrolled individuals receiving 1 or 2 drugs would remain uncontrolled if 3 drugs were used; this would raise the proportion with resistant hypertension. Lastly, different results would be obtained had lower cut points for those with diabetes or renal disease, but this would have greatly complicated the comparisons between groups. CONCLUSION: Though not rare, only a modest proportion of the hypertensive adult U.S. population would be currently considered to have drug-resistant hypertension. Many more individuals with uncon-
trolled hypertension are treated with only 12 classes of medication or are taking no antihypertensive drugs. Even among those classified here as resistant, inadequate diuretic therapy may be a potential modifiable target to improve hypertension control in this difficult to control group. Drug resistant hypertensive individuals on average have more cardiovascular disease, diabetes, obesity and renal dysfunction.

EVALUATION OF THE SATISFACTION OF GIM FACULTY WITH INPATIENT WARD ATTENDING SERVICE AND THE IMPACT OF INPATIENT DUTIES ON OUTPATIENT PRIMARY CARE ACCESS FOR A PILOT PART TIME HOSPITALIST PROGRAM Christine Perry 1;

Michal Hose 1; Paul Jain 1; Simone Kanter 1; Tina Bronner 1; Manjulika Woytowitz 1; Jennifer Newman1. 1VA HCS SD, La Jolla, California. (Tracking ID # 8671)

BACKGROUND: General Internal Medicine (GIM) faculty members at the academically affiliated VA San Diego (VA SD) attend annually on the inpatient service. A survey was administered to the GIM faculty to evaluate their satisfaction with the ward attending experience. Our work group assessed a pilot program of faculty participating in a part time hospitalist program. We evaluated the impact of these inpatient commitments on the providers availability in their primary care clinic. METHODS: GIM faculty completed an on-line survey in November 2008 and July 2010 eliciting demographic data and satisfaction with the inpatient service. Reponses were tallied using Spearman rank correlation for non-parametric tests. Four GIM physicians volunteered for a pilot hospitalist program. They rotated in 2 week periods, covering one of four ward teams. When not on wards these physicians resumed outpatient care for their established primary care panels. The remaining three teams were attended in traditional fashion by internal medicine faculty rotating in 3.5-week long blocks. Information was collected on outpatient access of members of the hospitalist team from September 2009 through June 2010, as measured by days until the third next available appointment.

RESULTS: 74 surveys were completed, 36 in November 2008 and 38 in July 2010. There was no difference between the time periods regarding satisfaction of ward attending, with 26/36 faculty satisfied with ward attending (72.2%) in 2008 and 24/38 (63.2%) satisfied in 2010 (p=0.4). The most common reason for dissatisfaction was the time away from clinic (52%) and impact on outpatient access (61%). In 2008 13/36 (36%) and in 2010 12/38 (32%) of respondents cited that they felt uncomfortable or out of practice managing inpatients. All hospitalists showed a significant increase in time to 3 rd next available clinic appointments before and during inpatient service. Providers on service had peaks in their time to 3 rd next available with a maximum of 3640 days and a minimum of 2836 days. All providers were able to make significant reductions in these parameters within 21 days of returning to their outpatient duties, resulting in baseline 3 rd next available ranging from a maximum of 114 days and a minimum of 01 day. CONCLUSION: Many faculty members at the VA SD are satisfied with their inpatient ward attending service. However, inpatient service impacts outpatient clinic access. The data demonstrates that time on the inpatient service results in a decline in outpatient availability for members of the part time pilot hospitalist team. Increasing emphasis is being placed by the VA SD on outpatient primary care access. The data

suggests that a dedicated hospitalist model at the VA SD, in which inpatient and outpatient responsibilities are split between distinct but collaborating groups of internists, would serve the institutions best interests in meeting national goals in outpatient access goals. Evaluation of the impact of inpatient service on the access of both pilot hospitalist and traditional attending physicians is ongoing.

DNR DOES NOT MEAN DO NOT TREAT: DATA FROM THE FIRST US ELECTRONIC POLST REGISTRY

Erik K. Fromme 1; Dana Zive 1; Terri Schmidt 1; Elizabeth Olszewski 1; Susan W. Tolle1. 1Oregon Health &Science University, Portland, Oregon. (Tracking ID # 8719)

BACKGROUND: The Physician Orders for Life Sustaining Treatment (POLST) form augments traditional methods for advance care planning by translating treatment preferences into medical orders. Developed in Oregon, POLST programs now exist or are developing in 33 US states and 2 other countries. POLST orders include CPR, scope of treatment, antibiotics, and artificial nutrition by tube. Scope of treatment in POLST is divided into comfort only meaning hospitalize only if comfort needs cannot be met in current setting, limited additional interventions meaning hospitalize for evaluation and treatment of medical problems but avoid ICU care, and full treatment including ICU care. The electronic POLST registry launched in December 2009 allowing emergency personnel and hospitals immediate and 24-hour access to patient POLST form information. Health professionals completing a POLST in Oregon are required (by legislative statute) to submit the form to the Registry unless the patient chooses to opt out. Thus the registry is both an innovation in advance care planning and a unique resource for understanding patient treatment preferences beyond resuscitation status.
METHODS: We analyzed all active forms signed and submitted from 12/3/09 to 12/2/10the Registrys first year of full operation. We calculated the prevalence of each POLST order to represent the pre-test probability of each preference. We calculated likelihood ratios to examine the predictive value of knowing a patients preferences for each order.
RESULTS: At the end of the first year there were 25,142 active POLST forms in the registry which is currently receiving approximately 3,000 forms per month from every Oregon county. Over 84% of POLST registrants were 65 or older (mean age=77.7 years, SD=12.9 years), and 61% are female. 72.3% of registrants had a DNR order. Of these, 49.6% of also had orders for comfort only, 43.8% had orders for limited additional interventions, and 6.6% had orders for full treatment. Figure 1 shows how many people chose each different combination of POLST orders. Table 1 shows the prevalence for each POLST order which reflect pre-test probabilities and the likelihood ratios associated with a preference for each order. Only 5.4% of registrants wanted maximum treatment in every category and only 6.6% wanted minimum treatment in every category. Thus, 89.9% of those with a DNR order want more than the minimum in at least one other category and 80.8% of those requesting CPR wanted less than the maximum in at least one other category.
CONCLUSION: The Oregon Electronic POLST Registry is a new resource for ensuring that patient preferences are available and actionable across care settings. Registry data demonstrate why clinicians should not use DNR status to infer more about patient wishes. Even for these mostly elderly patients extrapolating from a patient with a DNR order that they would want comfort measures only was almost exactly a 50/50 proposition. POLST orders for full treatment or comfort measures only have higher predictive value. See www.POLST.org for further details.

DISCLOSURE AND DOCUMENTATION OF UNINTENDED MEDICAL EVENTS (UMES): WHAT DO HEALTHCARE PROVIDERS BELIEVE? Vinita Singh 1; Mukta Panda 2; Christopher JL Cunningham 3; Dale C

Hetzler 4; Dan J Stanley2. 1Indiana University, Indianapolis, Indiana ;
2University of Tennessee, Chattanooga, Tennessee ; 3University Of Tennessee, Chattanooga, Tennessee ;
4Erlanger Health System, Chattanooga, Tennessee . (Tracking ID # 8728)
BACKGROUND: The AMA states it is an ethical requirement that a physician should deal honestly and openly with patients. In 2001 JCAHO added requirement to disclose unanticipated outcomes to accreditation standards. Full disclosure increases patient satisfaction and trust in physicians. Though studies suggest elements of complete disclosure, there are no national standards. Purpose: 1) Look for documentation of various elements of UMEs disclosure 2) Survey health care providers (HCPs) for their perceptions regarding UMEs disclosure METHODS: Chart review for following disclosure elements: who made and received disclosure; were persons documenting and reporting disclosure same; event facts; time from event to disclosure and documentation; locations of error and disclosure. An anonymous survey then was sent to all HCPs. RESULTS: 230 charts with reported UMEs Category E to I (derived from MERP medication scale), at a hospital system in Southeastern U.S. between 7/1/08- 6/30/09 were reviewed for documentation of minimum disclosure elements suggested by prior studies. Documentation was considered complete if it had all the elements mentioned above. 192 charts were included in study - 135 adults/ 57 pediatrics. Overall 9.89% of reviewed charts contained any disclosure documentation. Note that the absence of documentation in the chart does not mean that disclosure did not occur. This review was limited to the examination of charts for documentation of disclosure. (See table) Separate survey data was collected from a sample of physicians (n=65) and non-physicians (n=48) working within the same hospital system (total N=113, response rate 29%).(1) 68% physicians and 48% non-physicians indicated awareness of disclosure recommendations. (2) Physicians and non-physicians reported learning about disclosure recommendations from different sources. (3) 57% physicians and 35% non-physicians reported not being aware/informed of policy or guidelines for disclosure in this hospital (4) Differences were observed between physicians and non-physicians in terms of: perception of disclosure need and best person to provide disclosure in several example scenarios; importance of specific information within proper disclosure documentation; frequency with which certain factors hindered proper disclosureCONCLUSION: There is an incomplete understanding of unintended medical events, various levels of unintended medical events. This may lead to a lack of disclosure and its documentation. Developing explicit policies and structured templates coupled with multisource education of health care providers will assist in improving and promoting professional responsibility, decreasing litigation payouts and improving patient satisfaction.

Table 1:

THE IMPACT OF DIABETES MELLITUS ON SEXUAL FUNCTION IN ETHNICALLY DIVERSE WOMEN Kelli Copeland 1; Jennifer Creasman 1; Leslee Subak 1; Jeanette Brown 1; Stephen Van Den Eeden 2; David Thom 1; Alison Huang1. 1University of California San Francisco, San Francisco, California ; 2Kaiser Permamente Division of Research, Oakland, California . (Tracking ID # 8736)

BACKGROUND: Diabetes mellitus is a common chronic condition that can affect multiple dimensions of functioning and quality of life. While previous studies have indicated an over three-fold increased risk of sexual dysfunction in men with diabetes, the effect of diabetes on sexual function in women is poorly understood. METHODS: Sexual function was examined in an ethnically-diverse cohort of 2,270 women aged 40 to 85 years enrolled in the Kaiser Permanente Medical Care Program of Northern California, including 20% women with diabetes. Sexual function was assessed using self-administered questionnaire measures adapted from the validated Female Sexual Function Index. Diabetic end-organ complications were assessed by interviewer-administered questionnaires, with peripheral neuropathy assessed by the Michigan Neuropathy Screening Instrument, and kidney function assessed by measurement of serum creatinine. Use of medications, including insulin and oral diabetes medications, was assessed by direct review of medication bottles. Multivariable logistic

regression models compared sexual function outcomes (i.e., sexual desire/interest, frequency of sexual activity, overall sexual satisfaction, and specific problems such as difficulty with lubrication, arousal, orgasm, or pain) among diabetic women taking insulin, diabetic women not taking insulin, and non-diabetic women, adjusting for age, race, relationship status, menopause, body mass index, hysterectomy, oopherectomy, other medication use, and smoking. Additional multivariable models assessed relationships between diabetes-specific complications and worse sexual function among diabetic women. RESULTS: Of the 2,270 women, 139 (6%) had diabetes and were taking insulin, 347 (15%) had diabetes but were not taking insulin, and 1,784 (79%) did not have diabetes. The mean (SD) age of participants was 559.2 years and 44% (N=1006) were white, 18% (N=401) Latina, 20% (N=443) African-American, and 18% (N=401) Asian or Pacific Islander. Approximately half of women overall were at least moderately interested in sex (42% of diabetic women taking insulin, 38.1% of diabetic women not taking insulin, and 48% of non-diabetic women [P=0.02 for heterogeneity]). Of the diabetic women taking insulin, 61% reported less than monthly sexual activity, compared to 58% of diabetic women not taking insulin and 48% of non-diabetic women (P<0.01 for heterogeneity). Neither sexual interest nor frequency of sexual activity differed by diabetes category in multivariate analyses. Women with diabetes, both on insulin and not on insulin, were more likely to report low sexual satisfaction compared to non-diabetic women (OR=2.04, 95%CI=1.32-3.24 for those taking insulin; OR=1.41, 95%CI=1.03-1.93 for those not taking insulin), independent of other factors. Among sexually active women, diabetic women taking insulin were also more likely to report problems with lubrication (OR=2.48, 95% CI=1.40-4.41) and orgasm (OR=1.84, 95% CI=1.03-3.29). Among all diabetic women, end-organ complications such as heart disease, stroke, retinopathy, decreased kidney function, claudication, and peripheral neuropathy were associated with increased risk of decreased sexual function in one or more domain. CONCLUSION: Compared to non-diabetic women, women with diabetes are more likely to report low sexual satisfaction, independent of other demographic and clinical factors. Diabetic women taking insulin may also be at higher risk of specific sexual problems such as difficulty with
lubrication or orgasm. Multiple diabetic complications are associated with worse sexual functioning, suggesting that prevention of these complications may be important in preserving sexual function in diabetic women.

HYPERTENSION CONTROL IN DIABETICS IN A FEDERAL QUALIFIED HEALTH CARE CENTER

Nephertiti Efeovbokhan 1;
Venu Gourineni 1; Yan Xie 2; Manjunath Raju 1; Maria Bevilacqua 3; Ade Olomu1. 1Michigan State University, Department of Internal Medicine, East Lansing, Michigan ; 2Michigan State University, East Lansing, Michigan .
(Tracking ID # 8742)

BACKGROUND: Cardiovascular disease and not hyperglycemia is the leading cause of death in patients with diabetes mellitus (DM). Hypertension is particularly burdensome in diabetic patients particularly in low income groups, where the prevalence of uncontrolled hypertension is increased. Federal Qualified Health Centers (FQHCs) are designed to provide care for low income and medically underserved populations. Objectives: 1) to determine the rate of Blood Pressure (BP) control in patients with diabetes and hypertension, and 2) to determine the predictors of BP control in this population.

METHODS: Retrospective analysis of charts of all consecutive patients with cardiovascular disease, hypertension and diabetes mellitus (DM) seen in a FQHC in Michigan from January 1, 2006 to December 31, 2008 was performed. Uncontrolled hypertension was defined as Systolic BP >130 mm Hg and diastolic BP >80 mm Hg. Multivariable logistic regression was used to assess predictors of BP control.

RESULTS: Of 212 patients identified, 154 had hypertension, 122 had DM, and 88 had hypertension and DM. Of the diabetic population,53.28 % were men, mean (SD) age was 51.0 (12.9) years, HbA1C was8.04 (2.29), LDL was 106.42 (35.52). 61.32% had a BMI >30, 38.68% had a BMI >35, 36.89% were smokers, 72.95% had Medicaid insurance,13.93% had Medicare, and 13.11% had no insurance. We found 68.18% of Diabetics with hypertension were on ACE inhibitors/ARBs, 40.91% were on BB, and 45.45% were on Diuretics. BP control was

achieved in only 31.15% of patients with DM. In the cohort of patients whose BP was controlled, 42.86% had HBA1c>=7, while in those with uncontrolled BP,63.16% had HBA1c >=7 (p-value 0.22). A logistic regression model controlling for age, race, gender, type of insurance, BMI, number of medications used for BP control, number of clinic and emergency room visits found age to be associated with BP control (estimates= 0.0540, p-value <0.05)
CONCLUSION: We found that significant number of diabetic patients with hypertension do not have their BP controlled in a FQHC. There is underuse of ACE inhibitors/ARBs for BP control in this population. Our study revealed older diabetics are less likely to have their BP controlled. This underscores the urgent need for strategies to improve BP control in diabetics in FQHCs, especially among elderly patients who have a higher risk for cardiovascular and renal complications.
URBAN WOMENS PREFERENCES FOR LEARNING OF THEIR MAMMOGRAM RESULT: A QUALITATIVE STUDY Erin N. Marcus 1;
Darlene K. Drummond2. 1University of Miami Miller School of Medicine, Key Biscayne, Florida ; 2University of Miami School of Communication, Miami, Florida . (Tracking ID # 8755)
JGIM
ABSTRACTS
S21
BACKGROUND: Research suggests that communication of mammo-gram results is suboptimal for many ethnic minority women. The goals of our project were 1. To improve understanding of low-income inner-city English-speaking womens experiences learning of their mammogram result; 2. To elicit their preferences as to how the communication of mammogram results could be improved; and 3. To gather information to help inform the development of a new tool for communicating mammogram results.
METHODS: A convenience sample of 34 women was recruited in the community to participate in 4 focus groups, each of which was led by an African-American female moderator. Themes discussed included how each woman had learned of her result, how result reporting could be improved, and what types of interventions might be effective to improve womens understanding of their results. The investigators also showed the women a typical mammogram result letter and asked for their opinions. Two investigators separately performed a thematic analysis of the transcripts using an immersion and crystallization approach.
RESULTS: 36 women participated in the study. 85 % (n=29) self-identified as African-American. 39 % (n=14) qualified for Medicaid; 36% (n=13) reported that they lacked insurance. 56 % (n=20) reported an annual income of less than $10,000. Salient themes included general dissatisfaction with how results were reported, with some women saying that they did not recall receiving a letter or receiving a call informing them of their results. Several women reported anxiety simply learning of their results, even if they were normal. Many of the women said that the result notification letter contained words they could not understand, was vague, and did not effectively convey the need for follow-up. Women expressed a preference for learning of the result directly from their physician. Women were unaware of how common it is to be called back for a repeat imaging study, and wanted to be prepared for this possibility in advance, through informational videos and pamphlets. Women expressed a preference for print materials that included pictures, testimonials, and an action plan including a hotline to call with questions.
CONCLUSION: This qualitative study of a predominantly African-American, low-income population of inner city women suggests that current methods for reporting mammogram results are flawed. Advance education about what occurs after a mammogram may improve patients understanding of their results and reduce anxiety. To increase patient satisfaction, print materials informing women of their results should incorporate photographs and testimonials and include information about where to obtain a more detailed explanation about specific results.
MEASURING BLOOD PRESSURE FOR DECISION MAKING AND QUALITY REPORTING: WHERE AND

HOW MANY MEASURES? Benjamin Powers 1; Maren Olsen 2; Valerie Smith 2; Robert Woolson 2; Hayden Bosworth 2; Eugene Oddone2. 1Duke University and Durham VAMC, Durham, North Carolina; 2Duke University Medical Center and Durham VAMC, Durham, North Carolina. (Tracking ID # 8756)
BACKGROUND: There is uncertainty about the optimal setting and number of blood pressure (BP) measurements that should be used for clinical decision making and quality reporting. We sought to compare different strategies using home or clinic BP on the certainty with which patients could be classified as in or out of control.
METHODS: We analyzed 444 veterans with hypertension receiving primary care through the Durham Veterans Affairs Medical Center and
enrolled in a telephone self-management trial over 18 months. Blood pressure was measured repeatedly by three methods: standardized research BP measurements at 6 month intervals; clinic BP measurements obtained during outpatient visits; and home BP using a monitor that transmitted values electronically. Separate random effects models were fit to all available SBP measurements during the study period for research, home, and clinic values. The models included an overall mean (i.e., no change in SBP over time), an individual-level random effect which yielded an estimated between-person variance, and a measurement error which yielded an estimated within-individual variance. Assuming a bivariate normal distributions, we calculated the probability that an individuals true SBP was out of control according to guideline recommendations (SBP >140 mmHg for clinic or study measurements, SBP >135 for home measurements) given a range of observed mean SBP. We estimated these probabilities separately based on one SBP measurements or the average of 2, 5, or 10 measurements.
RESULTS: Patients provided 111,181 SBP measurements (3218 research; 7121 clinic; and 100,842 home) over 18 months. SBP control rates at baseline (mean SBP Short-term variability was large and similar across all three modes of measurement with a mean within-individual coefficient of variation of 10% (range: 1%-24%). No single clinic SBP between 120 mmHg and 160 mmHg allowed correct classification of a patient as in or out of control with >80% certainty (Figure 1). The impact of within-individual variability could be reduced significantly by averaging multiple measurements, with most benefit accrued at 56 measurements (Figure 2).
CONCLUSION: Physicians who want to be >80% certain they are correctly classifying patients blood pressure control should use the average of multiple measurements. Hypertension quality metrics based on a single clinic measurement misclassify a large proportion of patients and could be significantly improved with the incorporation of home blood pressure.
Figure 1. Probability of correct SBP classification based on clinic measurement

TREATMENT EFFECTS OF LINACLOTIDE ON BOWEL AND ABDOMINAL SYMPTOMS OF CHRONIC CONSTIPATION: POOLED EFFICACY AND SAFETY RESULTS FROM 2 RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE 3 TRIALS Bernard J Lavins 1; Anthony J Lembo 2; Harvey A Schneier 3; Steven J Shiff 3; James E MacDougall 1; Xinwei D Jia 3; Caroline B Kurtz 1; Mark G Currie 1; Jeffrey M Johnston1. 1Ironwood Pharmaceuticals, Cambridge, Massachusetts ; 2Beth Israel Deaconess Medical Center, Boston, Massachusetts ; 3Forest Research Institute, Jersey City, New Jersey . (Tracking ID # 8757)
BACKGROUND: Chronic constipation (CC) affects between 12 and 19% of the US population and can negatively impact patients health-related quality of life. The symptoms of CC include infrequent bowel movements (BMs), hard stools, straining during defecation, a sense of incomplete evacuation, abdominal discomfort and bloating. Many patients are dissatisfied with current treatment options, primarily due to inconsistent efficacy and associated side effects. Linaclotide is a minimally absorbed, guanylate cyclase type-C receptor agonist currently being
evaluated for the treatment of CC and irritable bowel syndrome with constipation. In two multicenter, randomized, double-blind, placebo-controlled, dual-dose, parallel-group Phase 3 trials, linaclotide improved

measures of bowel and abdominal symptoms in patients with CC. Here, pooled results from the two Phase 3 CC trials are presented. METHODS: Patients included in the trials reported a history of <3 spontaneous BMs per week (SBM: a BM occurring in the absence of any laxative, suppository, or enema use during the preceding 24 hours) plus at least one of the following symptoms during at least 25% of defecations: straining, hard or lumpy stools, or a sense of incomplete evacuation, for at least 12 weeks (which need not have been consecutive) in the preceding 12 months. In addition, patients also had to report during the 2-week baseline period: <3 complete SBMs (CSBM: an SBM accompanied by a sensation of complete evacuation)/week and </=6 SBMs/week. Patients meeting these criteria were randomized to oral once daily linaclotide 133 or 266mcg, or placebo for 12 weeks. The primary efficacy endpoint was the 12-week overall CSBM responder rate (>/=3 CSBM/week with increase of >/= 1 CSBM/week from baseline for 9 of 12 weeks). In a post-hoc analysis, the change from baseline in abdominal discomfort and bloating in patients with at least moderate abdominal pain at baseline (score >/=3 on a 1 [none] to 5 [very severe] point severity scale; 23% of the Intent-to-Treat [ITT] population) was assessed. P values were calculated using a Cochran Mantel Haenszel test controlling for study and geographic region for CSBM responder rates and an Analysis of Covariance model with study, treatment group, and geographic region as factors and baseline value as covariate for change from baseline endpoints. RESULTS: In these two Phase 3 trials, a total of 1272 patients with CC were included in the ITT population and were randomized to placebo (n=424), linaclotide 133mcg (n=430), and linaclotide 266mcg (n=418). Baseline demographic and clinical characteristics were similar across treatment groups. Across both trials, approximately 70% of patients did not have a CSBM during the baseline period. For the 12-week treatment period, the overall CSBM responder rates were 4.7%, 18.6%, and 20.3% for placebo, linaclotide 133mcg, and linaclotide 266mcg, respectively (p<0.0001 for both comparisons). The weekly mean CSBM rate is displayed in Figure 1. Statistically significant separation from placebo for CSBM and SBM rates was observed within 24 hours of treatment. Secondary endpoints, including change from baseline in CSBMs, SBMs, stool consistency, straining, and constipation severity were statistically significantly improved with linaclotide 133 and 266mcg compared to placebo (Table 1). Abdominal symptoms were also significantly improved, with decrease in

bloating severity more than 2-fold greater than the placebo response; in addition, in the subpopulation with at least moderate abdominal pain at baseline, the improvement in abdominal discomfort and bloating was nearly one full unit on the 15 severity scale (Table 1, bottom). Diarrhea was the most commonly reported treatment-related adverse event, resulting in discontinuation rates of 0.5%, 4.4%, and 3.8% in placebo, linaclotide 133mcg, and linaclotide 266mcg patients, respectively, in the ITT group; discontinuation rates in the moderate to very severe abdominal pain
subpopulation were even lower, 0%, 2.0%, and 2.1% for placebo, linaclotide 133mcg, and linaclotide 266mcg, respectively.
CONCLUSION: In two large Phase 3 trials, linaclotide treatment statistically significantly improved measures of bowel and abdominal symptoms, as well as constipation severity, in patients with CC. Abdominal symptoms of discomfort and bloating were also statistically significantly improved in patients with at least moderate abdominal pain at baseline. Diarrhea was the most common adverse event.

RACIAL DISPARITIES IN BREAST CANCER STAGE AT DIAGNOSIS IN THE MAMMOGRAPHY ERA Neal Chatterjee 1; Yulei He 2; Nancy L Keating3.
1Department of Medicine, Massachusetts General Hospital, Boston, Massachusetts ; 2Department of Health Care Policy, Harvard Medical School, Boston, Massachusetts ; 3Department of Health Care Policy, Harvard Medical School and the Division of General Internal Medicine, Brigham and Womens Hospital, Boston, Massachusetts . (Tracking ID # 8760)
BACKGROUND: The efficacy of mammographic screening is related to its ability to shift stage at diagnosis from distant to earlier-stage disease. Despite equivalent rates of mammography since the late-1990 s, black women have higher breast cancer mortality than white women. Since stage at diagnosis is the strongest predictor of survival in breast cancer, we sought to assess dynamic changes in stage at breast cancer diagnosis for black and white women since mammography became available.
JGIM
ABSTRACTS
S25
METHODS: Population-based observational study involving 143,249 white and 13,571 black women aged 5069 diagnosed with invasive breast cancer between 19822007 living in a Surveillance, Epidemiology, and End Results (SEER) region. We assessed odds of distant (versus local or regional) disease at diagnosis by race, adjusted for patient demographic (age, marital status, SEER region) and socioeconomic factors (area-level estimates of insurance status, education, income) known to affect stage at diagnosis. Behavioral Risk Factor Surveillance System data were used to calculate biennial mammography rates for black and white women, aged 5170, from 1990 to 2006 in all states where the SEER9 regions were located. We used logistic regression to assess the association of year of diagnosis and race with distant cancer diagnosis. Logistic regression was also used to compare linear trends in rates of distant cancer diagnosis for black and white women, before and after 1998 (a time corresponding to peak mammography for both races). Year was treated as a continuous variable and an indicator variable was included for pre vs. post-1998 to assess change.
RESULTS: Overall, 5.8% of whites and 10.2% of blacks were diagnosed with distant breast cancer. The black-white disparity in the proportion of distant cancers narrowed until 1998 (adjusted difference 0.65%), before increasing (Figure). Biennial mammography rates in the SEER9 states peaked in 2000 for both races; rates were lower for blacks than whites in the early 1990 s, but equalized by 1996 (Figure). Between 1982 and 1997, the proportion of distant cancers decreased over time for both black women (adjusted odds ratio [AOR] per year=0.973 [95% CI=0.960-0.987]) and
white women (AOR per year=0.978 [95% CI=0.974-0.984]), and the rate of decline for black and white women did not differ significantly (P for interaction=0.61). From 19982007, the odds of distant breast cancers increased more rapidly for black women (AOR per year=1.036 [95% CI=1.014-1.060]) than for white women (AOR per year=1.011 [95% CI=1.001-1.021]) (P for interaction=0.04). Sensitivity analyses using 1997 and 1999 as alternate time points did not change statistical associations. CONCLUSION: After a narrowing of the black-white disparity in the proportion of distant breast cancers diagnosed until 1998, the proportion of distant-stage cancers has since increased more rapidly in black women than white women. The narrowing of the black-white disparity coincides with peak rates of mammography for black and white women. We propose two possible explanations for our findings. First, given more aggressive tumor biology in black women, the disproportionate increase of distant disease may reflect less benefit for black women at current screening intervals (every 12 years). Second, rates of mammography have declined for both black and white women since 2000. In a background of

different tumor biology, similar decrements in screening rates may be associated with widening of the stage at diagnosis disparity. Black women may benefit more from higher absolute rates of mammography than white women. Given the marked survival difference between early and late stage breast cancer, further attention to racial disparities in stage at diagnosis is warranted.

THE METABOLIC SYNDROME IN OBESE PATIENTS WITH BINGE EATING DISORDER IN PRIMARY CARE CLINICS Katherine C. McKenzie 1; Rachel Barnes 2; Abbe Boeke 3; Inginia Genao 4; Rina Garcia 5; Matthew Ellman 4; Peter Ellis 3; Robin Masheb 3; Carlos Grilo6.

1Yale University School of Medicine, New Haven, Connecticut ; 2Yale School of Medicine, New Haven, Connecticut ; 3Yale University School of Medicine, New Haven, Connecticut ; 4Yale University School of Medicine, New Haven, Connecticut ; 5Yale University School of Medicine, Middletown, Connecticut ; 6Yale University School of Medicine, Yale University, New Haven, Connecticut . (Tracking ID # 8779)

BACKGROUND: Obesity is a heterogeneous problem, and research has highlighted the clinical significance of the subgroup of patients with binge eating disorder (BED). BED is characterized by recurrent episodes of binge eating (overeating unusually large quantities of food while experiencing a subjective loss of control) without inappropriate weight compensatory behaviors (which characterize bulimia nervosa). The distribution and nature of the metabolic syndrome in obese patients with BED is largely unknown and requires investigation, particularly in general internal medicine settings.

METHODS: A cross-sectional analysis of 81 consecutive treatment-seeking obese BED patients. Patients with and without metabolic syndrome were compared on demographic features and current and historical eating- and weight-related variables.

RESULTS: Forty-three percent of patients met criteria for metabolic syndrome. A significantly higher proportion of men (66%) than women (35%) met criteria for metabolic syndrome; patients with versus without metabolic syndrome did not differ significantly in ethnicity or body mass index. Patients with versus without metabolic syndrome did not differ significantly in binge-eating frequency, severity of eating disorder psychopathology, or depression. ANCOVAs, controlling for gender, revealed that patients without the metabolic syndrome started dieting at a significantly younger age, spent more of their adult lives dieting, and reported more current dietary restriction than patients with metabolic syndrome.

CONCLUSION: Metabolic syndrome is common in obese patients with BED in primary care settings and is associated with fewer dieting behaviors. These findings suggest that certain lifestyle behaviors, such as increased dietary restriction, may be potential targets for intervention with metabolic syndrome.

RISK OF THIAZIDE-INDUCED HYPONATREMIA IN PATIENTS WITH HYPERTENSION Alexander A. Leung 1; Adam Wright 1; Valeria Pazo 1; Andrew Karson 2; David W. Bates1. 1Brigham and Womens Hospital, Boston, Massachusetts; 2Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 8786)

BACKGROUND: Although hyponatremia is a well-recognized and costly complication of treatment with thiazide diuretics, the risk of thiazide-induced hyponatremia has not been defined in routine care. Thus, we designed this study to assess the risk of incident hyponatremia in patients treated with thiazides.

METHODS: We conducted an inception cohort study using a multicenter clinical research registry to identify 3238 adult outpatients that were newly treated for hypertension between January 1, 2000 and December 31, 2005 at two teaching hospitals in Boston, Massachusetts, and followed them for up to 10 years. Patients with prior hyponatremia were excluded. RESULTS: Of 152 patients exposed to thiazide diuretics (mean age 59 years), 67 (44%) developed hyponatremia, defined as serum sodium less than 133 mmol/L. Among those that developed hyponatremia with thiazides, the median time to event was 1.8 years (655 days). The adjusted rate of incident hyponatremia was 80 cases per 1000 person-years for patients treated with thiazides compared to 27 cases per 1000 person-years in those without thiazides. Patients exposed to thiazides were more likely to

develop hyponatremia (adjusted rate ratio, 3.13; 95% CI, 2.34 to 4.17) and the relative risk was similar regardless of age or sex. Similarly, the risk of hospitalizations associated with hyponatremia (adjusted rate ratio, 2.94; 95% CI, 1.97 to 4.39) and all hospitalizations (adjusted rate ratio, 1.34; 95% CI, 1.05 to 1.71) were higher in those treated with thiazides. There was no significant difference in mortality.
The number needed to treat to result in one extraneous incident case of hyponatremia in 5 years was 4.55 (95% CI, 3.36 to 7.04). CONCLUSION: Our findings suggest that the occurrence of hyponatremia and associated hospitalizations among patients receiving thiazide diuretics are common with substantial long-term risks. We found that over 4 in 10 patients exposed to thiazides develop hyponatremia when followed over a decade.
TIME-DEPENDENCY OF OUTCOME RELATIONSHIPS FOR DRUG-ELUTING STENTS VERSUS BARE-METAL STENTS Alexander A. Leung 1; Danielle A. Southern 1; P. Diane Galbraith 1; Merril L. Knudtson 1; William A. Ghali1. 1University of Calgary, Calgary, Alberta. (Tracking ID # 8787)
BACKGROUND: We previously reported outcomes on a population-based cohort that suggested that the early benefit from revascularization with drug-eluting stents attenuated over time, with perhaps even a shift toward poorer outcomes after one year. To better characterize this finding, we sought to investigate the long-term outcomes associated with drug-eluting stents compared to bare-metal stents with an analysis extending to 7 years of follow-up.
METHODS: We performed an extended analysis on a cohort of 6440 patients who underwent percutaneous coronary intervention between April 1, 2003 an March 31, 2005 using a prospective multicenter provincial clinical registry, and compared rates of death, and of death or repeat revascularization over 7 years of follow-up. We determined risk-adjusted hazard ratios at moments in time using spline analysis from Cox proportional hazards modeling.
RESULTS: During the 7 years of observation, the relative risks for death or the composite outcome of death or repeat revascularization varied over time. There was suggestion of early benefit associated with drug-eluting stents in the first year following implantation. Subsequently, at one year post-procedure and beyond, there was a shift in relative risks over time with a higher hazard for poor outcomes in drug-eluting stent patients (see figure). The adjusted relative risks early in the first year for death and the composite outcome of death or repeat revascularization were 0.26 (95% CI, 0.14 to 0.48) and 0.69 (95% CI, 0.44 to 1.08), respectively. By 7 years, the adjusted relative risks for death and the composite outcome of death or repeat revascularization rose to 1.52 (95% CI, 0.96 to 2.42) and 1.53 (95% CI, 0.96 to2.42), respectively.

CONCLUSION: Revascularization with drug-eluting stents is associated with significantly better outcomes within the first year only. Thereafter, a signal for a progressively increasing risk is seen, most notably for the composite outcome of death or repeat revascularization.
DYING ON THE STREETS Thuy Pham 1; Sara Doorley 1; Cheryl Ho1.
1Santa Clara Valley Medical Center, San Jose, California. (Tracking ID # 8875)
BACKGROUND: The Valley Homeless Healthcare Program (VHHP) was established in 2003 to provide medical and psychiatric care to the homeless of Santa Clara County. This study aims to explore VHHPs patients experiences and views on death and dying in order to implement programs that would bridge barriers to effective healthcare. METHODS: Participants were recruited from a primary care clinic for the homeless in San Jose, California. Inclusion criteria for the study included a history of homelessness, age 18 or older, ability to speak English and give written informed consent. Participants were asked to fill out a demographic survey then join a focus group to discuss their experiences with death, experiences with memorial services, utility of a memorial service, fear of death and dying, exposure and interest in advanced directive. This data was analyzed manually using a method called content analysis. RESULTS: There were a total of 30 participants,

ages 26 to 60, 21 men and 9 women. Of the 30 participants, 19 were Caucasian, 4 were African American, 6 were Hispanic, with 1 Other. The participants knew a total of 45 homeless people who died in the past year. 69% of those deaths were caused by substance abuse or violent crime. Common themes regarding fear about death and dying included physical pain and suffering, leaving a burden for the people left behind, the afterlife, no fear, dying alone and not being found. One participant said, At this moment, I dont fear death. Death will be a blessing. Another participant stated, There are more reasons to die when you are homeless because no one cares about you. One of the women said softly, I live under the freeway and am a little old woman, so its scary. Overall, 67% of the participants would want a memorial service after they die, 7% said no, and 26% were undecided. One participant said no because there would not be anything nice said. Others did not like funerals in general or did not care. 87% of the participants would find it helpful to have a discussion on how they want to be treated when they are too sick to make decisions for themselves and write down an advanced directive.
CONCLUSION: Homeless persons in the Valley Homeless Healthcare Program have frequent encounters with death and favor clinic-based end-of-life discussions and documentation as well as a memorial service. The variation in participants answers illustrates the complexity of the topic of death and dying. Therefore, further studies with more participants in different primary care clinics for the homeless are needed to validate these needs and the utility of implementing programs to address these needs.

HYPERTENSION CONTROL IN A FEDERAL QUALIFIED HEALTH CENTER IN MICHIGAN: HOW ARE WE DOING?

Ade Olomu 1;
Nephertiti Efeovbokhan 1; Venu Gourineni 2; Manjunath Raju 3; Yan Xie 3; Margaret Holmes-Rovner5.
1Michigan State University, Department of Internal Medicine, East Lansing, Michigan ; 2Michigan State University, Department of Medicine, East Lansing, Michigan ; 3Michigan State University, East Lansing, Michigan . (Tracking ID # 8879)

BACKGROUND: Rates of hypertension awareness and treatment have increased with recent reports from the National Health and Nutrition Examination survey (NHANES) estimating blood pressure control nationally at about 50%, does this hold true in our Federal qualified health centers (FQHCs)? FQHCs are designed to provide care for low income and medically underserved populations. Hypertension is particularly burdensome in low income groups, where the prevalence of uncontrolled hypertension is increased. Objectives: 1) to determine the rate of blood pressure control in a FQHC. 2) to determine the predictors of Blood Pressure (BP) control.
METHODS: Retrospective analysis of charts of all consecutive patients with hypertension, coronary artery disease and or, diabetes mellitus (DM) seen in a FQHC in Michigan from January 1, 2006 to December 31, 2008. Uncontrolled hypertension was defined as Systolic BP >140 mmHg (>130 mm Hg in patients with DM) and diastolic BP >90 mmHg (>80 mm Hg in patients with DM). Multivariable logistic regression was used to assess predictors of BP control.
RESULTS: Of 212 patients identified, 154 had hypertension, 122 had DM, and 88 had hypertension and DM. The mean age was 53.9 +11.6 years,51.3 % were men, mean BMI was 34.1 +10.5, 74.53% had Medicaid,11.32% had Medicare, 1.42% had private insurance and 12.74% had no

insurance. We found 44.81% of hypertensive patients were on diuretics,68.18% of Diabetics with hypertension were on ACE inhibitors/ARBs. BP control was achieved in 38.21 % of entire cohort and in 31.15% of patients with DM. A logistic regression model controlling for age, race, gender, type of insurance, BMI, number of medications used for BP control, number of clinic and emergency room visits found only female gender (OR=2.6, 95% CI:1.05, 6.37) to be associated with BP control.
CONCLUSION: We found that significant numbers of hypertensive patients were not adequately treated and fewer had BP controlled. Our study revealed female gender disparity and gross underuse of guideline recommended medications for BP control, especially among patients with diabetes. This underscores the urgent need for strategies to improve BP control and adherence to guideline recommendations for BP management in

FQHCs.

TOBACCO DEPENDENCE TREATMENT INTERVENTION FOR HOSPITALIZED SMOKERS: A RANDOMIZED, CONTROLLED TRIAL UTILIZING VARENICLINE Michael B. Steinberg 1; Jennifer Randall 1; Shelley Greenhaus1. 1UMDNJ-Robert Wood Johnson Medical School, New Brunswick, New Jersey. (Tracking ID # 8934)

BACKGROUND: Despite clear medical reasons to quit smoking, patients with medical illness continue to smoke at high rates. The hospital can be an important opportunity for smoking cessation interventions, but the use of tobacco treatments in this setting is limited. Previous studies indicate that intensity of treatment and quality of post-discharge follow-up are key predictors of abstinence. This study evaluates the benefit of initiating a comprehensive tobacco treatment intervention, including varenicline, during hospitalization. METHODS: Seventy-nine smokers admitted to a 584-bed university-based hospital with various diagnoses were enrolled in a randomized, double-blinded, placebo controlled trial from August 2007 to March 2009. A comprehensive treatment intervention, including varenicline or placebo and face-to-face outpatient follow-up, was utilized. Follow-up data collection occurred at weeks 4, 12, and 24. Primary outcome was exhaled carbon monoxide confirmed 7-day point abstinence at 24 weeks following discharge. Secondary outcomes included abstinence at 4 and 12 weeks following discharge; reported withdrawal symptoms; motivation to stop smoking; utilization of outpatient treatment following discharge; and composite medical outcome or death.

RESULTS: Overall abstinence for all subjects was 27% at 24 weeks. There was no difference in abstinence rates at 24 weeks between varenicline and placebo treatment groups (23% vs. 31%). There were non-significant differences in adherence to medication treatments between the varenicline and placebo groups (56% vs. 78%; p=0.12). Among subjects who were adherent to the medication protocol, there was a non-statistically higher abstinence rate at 24-week follow up in the varenicline group compared with placebo (80% vs. 56%; p=0.2). Utilization of the outpatient treatment component was quite high with40.5% of all subjects attending treatment at the Tobacco Dependence Clinic. Those subjects who attended treatment had significantly higher abstinence rates compared with those who did not attend treatment(53.1% vs. 8.5%, p There were no significant differences in motivation to stop smoking or changes in withdrawal symptoms. During the follow-up period, 23 subjects were re-hospitalized or treated in the emergency department with no significant difference between treatment groups (13 varenicline vs. 10 placebo).

CONCLUSION: Varenicline used in the hospital setting and immediately following discharge for smoking cessation appears safe, but it is unclear how effective it is when initiated in this setting. The benefit of face-to-face treatment following discharge and interventions to improve these follow-up rates may be important to achieving success in tobacco cessation for hospitalized smokers.

SCHOLARLY WORK OF CLINICIAN EDUCATOR FACULTY: A NATIONAL SURVEY OF GENERAL INTERNAL MEDICINE DIVISION DIRECTORS Hsin-Chieh Yeh 1; Amanda Bertram 1; Frederick L Brancati 1; Joseph Cofrancesco1. 1Johns Hopkins University, Baltimore, Maryland. (Tracking ID # 8947)

BACKGROUND: Although many medical schools expect clinician-educators (CEs) to produce external scholarship to earn promotion, the value of specific scholarly products and the availability of institutional support for scholarship are uncertain. We therefore conducted a national survey of GIM Division Chiefs concerning CE scholarship.

METHODS: A sampling frame for US GIM Division Chiefs was assembled from: (1) AAMC list of accredited medical schools; (2) SGIM membership directory; (3) ACLGIM membership directory; (4) GIM Division websites; and (5) telephone calls to GIM Division offices. For institutions with more than one GIM division, each Chief was surveyed. The survey included 4 sections: (1) general information; (2) rating of the importance of CE scholarly activities for promotion to Associate Professor; (3) availability of institutional research support for CEs; and (4) an open-ended hypothetical question If you had $100,000 per year to spend to enhance the scholarly productivity of your CEs, how would you spend it?.

RESULTS: Of the 134 AAMC accredited medical schools, we identified 145 Chiefs in 128 GIM divisions, excluding Johns Hopkins. To date, we received responses from 54 Chiefs (37%) from 51 institutions. There were no significant institutional differences between responders and non-responders regarding geographic region (p=0.45), number of medical students (p=0.26), or quartile of NIH research funding (p=0.47). Among responding Chiefs, median duration of service was 6 years (IQR: 311); 27% were women. They reported a median number of full-time CEs per GIM Division of 20 (inter-quartile range (IQR): 1132). 73% of GIM Divisions had a separate promotion track for CEs. The Figure illustrates the distribution of perceived importance of various scholarly activities in promotion of CEs to Associate Professor. Curriculum development and administration, presentations at national meetings and other institutions, and review articles and book chapters were all rated as most/very important or important/somewhat important by over 90% of Chiefs. The exception was publishing original peer-reviewed articles: about half of Chiefs surveyed rated these most/very important, but slightly less than half rated these not important at all. This difference was significantly associated with having separate promotion tracks: in Divisions with a separate track, 37% of Chiefs rated publishing original articles most/very important vs. 80% in Divisions without a separate track (p=0.02). Many Chiefs lacked divisional resources to promote CE scholarship, including lack of protected time (72%), project coordination (61%), overall career mentorship (46%), and statistical analysis (43%). If $100,000 per year were available to enhance the scholarly productivity of CEs, Chiefs most frequently cited the following priorities: faculty development (39%), protected time (29%), methods/statistics support (24%), project coordination/assistance (24%), and project funding (22%).

CONCLUSION: Scholarly productivity is important for promotion of CEs and there is a wide range of acceptable products. Original, peer-reviewed articles are very important in about half of GIM Divisions, but Chiefs report limited resources to facilitate original scholarship. Investment in core statistical support, faculty mentorship, and project coordination represent promising approaches to improve CE scholarly productivity.

VIEWS ON END-OF-LIFE CARE AMONG SOUTH ASIANS LIVING IN THE US Rashmi K. Sharma 1; Rashmi K. Sharma 1; Nidhi Khosla 2; James A. Tulsky 3; Joseph A. Carrese3. 1Northwestern University, Chicago, Illinois ; 2Johns Hopkins University, Baltimore, Maryland ;
3Duke, Durham, North Carolina . (Tracking ID # 8989) BACKGROUND: End-of-life care preferences vary across racial/ethnic groups and are likely influenced by cultural values and views. However, the way in which culture affects end-of-life care preferences among immigrant groups in the U.S. and their offspring is still poorly understood, especially among South Asians. Therefore, we sought to examine the values and views that influence end-of-life care preferences among first and second generation South Asians living in the United States. METHODS: This qualitative study used purposive sampling to recruit 12 first generation and 11 second generation South Asians in the mid-Atlantic region. Four focus groups (two first generation groups and two second generation groups) were conducted. Audio-recordings of the focus group sessions were transcribed verbatim, independently reviewed,
and coded by two investigators using Atlas.ti 6.0 to perform an editing style analysis. This process led to the generation of several themes and sub-themes.
RESULTS: First generation participants ranged in age from 41 to 76 years and were evenly split by gender. Second generation participants ranged in age from 23 to 36 years and included seven women and four men. All participants were highly educated, most were Hindu, and two thirds were studying or working in a healthcare field. Several themes emerged:1. Attitudes toward death and suffering-Death: Participants attributed a greater acceptance of death in South Asian culture to cultural beliefs (e.g., reincarnation).-Suffering: Most felt suffering should be treated even if it resulted from ones karma.2. Family duty: dynamics, specific roles, and expectations

-Family dynamics: Large family sizes, geographic distances, and traditional gender roles led to complex family dynamics which complicated EOL communication and decision making.

-Special roles: Traditionally, aging parents were cared for by the eldest son, but roles are changing due to education and urbanization. -Expectations: Strong sense of duty to care for family held by all, but first generation participants expected less from their children because of western emphasis on individuality. Second generation participants retained a sense of duty to care for aging parents but were concerned about resources to provide care at home.3. Self-determination and sociocultural considerations: -Information disclosure: Most preferred full disclosure. Lack of social support in the U.S. cited as a reason for preferring full disclosure in the U.S. but not in India.-Advance care planning: Patient preferences were often not discussed with family members leading to uncertainty and misconceptions. Several participants supported the use of advance directives to reduce family member decision-making burden rather than for the traditional rationale of patient self-determination.
CONCLUSION: In this study of first and second generation South Asians in the U.S., we found that many traditional cultural values, such as filial duty, greatly influenced care preferences at the end of life and retained importance across generations. Participants also described cultural challenges due to complex family dynamics, lack of explicit discussion between patients and other family members, and a tension between wanting to meet traditional expectations and an inability to do so in the face of U.S. social realities. Clinicians caring for South Asian patients at the end of life may be better able to assess care preferences after exploring the complex interplay between traditional expectations, family duty and dynamics, and specific social realities for each patient.
DISEASE PREVALENCE AND AGE DISTRIBUTION OF NEW FEMALE PATIENTS ATTENDING A GENERAL OUTPATIENT CLINIC AT A MEDICAL SCHOOL HOSPITAL IN JAPAN Yuta Sakanishi 1; Yuichiro Eguchi 2; Midori Nishii 3; Naoko Eguchi 2; Motoshi Fujiwara 3; Hitoshi Eguchi 3; Masaki Tago 3; Satoshi Matsunaga 3; Tsuneaki Yoshioka 3; Shu Soejima 3; Sei Emura 4; Shunzo 1; Takashi KoizumiSugioka5. 1Saga Medical School, Saga, N/A ; 2General Medicine, Medical School, Saga, N/A ; 3General Medicine, Saga Medical School, Saga, N/A ; 4Center for Graduate Medical Education Development and Research, Saga Medical School, Saga, N/A ; 5Community Medical Support Institute, Medical School of General Medicine, Medical School, Saga, Saga, N/A, N/A . (Tracking ID # 9024)
BACKGROUND: Information on the disease prevalences and age distributions of outpatient populations is needed to improve the quality of outpatient care and to assess the role of academic medical centers in the community. Our preliminary retrospective study investigated the age distribution of over 4,000 first-visit patients over 1 year; female patients showed bimodal peaks in their 20 s and 50-60 s, whereas the incidence of new male patients in their 60 s peaked. The aim of the current study was to identify the medical background associated with this age distribution in new female patients presenting at the outpatient clinic of a medical school hospital.
METHODS: The initial diagnosis on the first day of patient attendance was prospectively recorded in the electronic medical records, using a template, between October 2009 and June 2010. Patients with a referral form were excluded. The initial diagnoses were classified according to the International Classification of Primary Care codes (ICPC-2, Oxford University Press, 1998).
RESULTS: A total of 1,166 new female patients were enrolled during the study period. Their age distribution showed bimodal peaks in their 20 s and 50-60 s. The prevalences of the initial diagnoses classified by ICPC code were: gastrointestinal disease (13.1%), orthopedic disorders (14.3%), and respiratory diseases (11.9%). The age distributions of new female patients with gastrointestinal disease and respiratory disease showed bimodal peaks, while that for orthopedic disorders showed a single peak at over 50 years. The prevalences of initial diagnoses in the late 30 s-40 s were similar to those in other generations.

CONCLUSION: The age distribution of new female patients attending the outpatient clinic at a university hospital showed bimodal peaks for those in their 20 s and 50-60 s. This distribution was not associated with age-related disease prevalences. These results suggest that some patients have problems visiting university hospital outpatient clinics. Further studies are needed to identify the social obstacles to accessibility inpatients in their late 30-40 s, and to improve the quality of care for initial medical visits.

THE INFLUENCE OF FINANCIAL STRESSORS ON FUTURE CAREER CHOICES OF MEDICAL STUDENTS AND RESIDENTS ERIN W. KINNEY 1; PHILIP SCHERER 1; RAMYA EMBAR SRINIVASAN 1; CHRISTOPHER J. CUNNINGHAM 2; VICTOR O. KOLADE 1; Mukta Panda1. 1University of Tennessee College of Medicine Chattanooga, Chattanooga, Tennessee; 2University of Tennessee Chattanooga, Chattanooga, Tennessee. (Tracking ID # 9027)

BACKGROUND: With average medical student debt surpassing $130,000 (Kerr and Brown, 2006), financial concerns are among the top stressors adversely impacting resident quality of life. Financial stress can influence ultimate career choice and may affect the quality of patient care residents provide. Financial instruction is not generally a fundamental component of medical education. This pilot study aims at assessing the need for financial education and to develop an effective, tailored curriculum to decrease resident financial stress and ultimately improve patient care. METHODS: At one academic medical center, a pre-survey was distributed to residents and medical students to assess financial knowledge and stressors using a validated stress scale. Data was collected via an online survey after informed consent was obtained. Forty-eight residents (29%) and 17 students (33.3%) consented to participate. Identifiable data was managed by a third-party consultant to ensure confidentiality and was de-identified prior to being analyzed by the study team. Data analysis was performed with descriptive statistics. RESULTS: Pre-survey results show similar resident and medical student demographics. The average resident and student owe $156,137.92 and $136,958 in student loans, respectively. More students than residents believe they will eventually practice in an academic position. 43.8% of students believe that their debt will/may influence their specialty choice. 42.1% of residents believe that their debt influenced their specialty choice. On a perceived pressure-stress scale pertaining to personal finances, resident scored 8.05/14 and students scored 8.27/14. On a perceived threat-stress scale pertaining to finances, residents scored 7.37/16 and students scored 6.53/16. 54% of residents and 12.5% of students have experience with financial education. Greater than 80% of students and residents believe it is important for residents to receive training in personal and professional finance and are interested in attending lectures addressing basic financial concepts.

CONCLUSION: Medical students and residents accrue considerable student loan debt that causes stress and may affect career choices. For instance, more students than residents wish to practice in an academic position. Residents and students alike experience significant pressure and threat stress regarding their personal finances. A larger number of residents than students received some financial education, perhaps indicating an educational void in medical school not addressed by mandatory federal loan counseling. Residents and students expressed a desire for more extensive financial preparation for medical practice and personal life. Structured financial training may alleviate financial stress during medical education and allow students and residents to make career choices based on interest and professional goals as opposed to financial constraints, potentially leading to better patient care. Kerr, J. R. and Brown, J.J. Costs of a medical education: comparison with graduate education in law and business. J Am Coll Radiol, 2006, 3(2): 122130.

A QUALITATIVE APPROACH TO ASSESSING MEDICATION-RELATED ALERTING IN ELECTRONIC MEDICAL RECORDS Shobha Phansalkar 1;
Marianne Zachariah 2; Kathrin Cresswell 3; Meryl Bloomrosen 4; David W. Bates5. 1Brigham and Womens

Hospital and Harvard Medical School, Wellesley, Massachusetts ; 2Partners HealthCare Systems, Wellesley, Massachusetts ; 3The University of Edinburgh, Edinburgh, N/A ;
4American Medical Informatics Association, Bethesda, Maryland ;
5Division of General Internal Medicine, Brigham and Womens Hospital, Boston, Massachusetts . (Tracking ID # 9038)
BACKGROUND: Improving EHR adoption represents a key initiative of the current healthcare administration. Closely tied to achieving the benefits of EHRs is the provision of clinically meaningful decision support. Medication-related decision support (MDS) has the potential to prevent harm but is often ignored by physicians due to excessive alerting. We conducted a qualitative study to explore factors related to successful adoption of medication-related alerts in EHRs.
METHODS: We conducted semi-structured interviews with 42 end-users from 6 healthcare institutions, using 4 inpatient and 8 outpatient EHRs with MDS functionalities. Thematic analysis was used to identify underlying factors which emerged from consensus between two independent reviewers.
RESULTS: Reviewers assigned 1,157 statements to 31 thematic codes associated with good inter-rater agreement [Cohens kappa=0.69], which fell into 4 constructs (Implementation, Workflow, Users Perceptions, and Alert Characteristics). Implementation considerations related to: MDS development, Implementation issues (training, users ability to customize alerts, and mechanisms to provide feedback), Knowledge source for obtaining MDS, and Institutional governance and leadership overseeing MDS. Workflow considerations related to the timing of receiving alerts and the expected response from the user. Attitudes that influenced users responses towards MDS related to alert overload and users trust in the relevance of alerts. Users identified characteristics of optimal alerts, such as informational content, design and display, types of alerts available, and ability to override them.
CONCLUSION: Without effective implementation strategies, MDS can be intrusive to the clinician workflow. This study provides insight into providers perceptions on successful adoption of medication-related alerts. Findings of the study have implications on effective design and implementation of alerts impacting provider behavior.
3-YEAR FOLLOW-UP FROM A CLUSTER-RANDOMIZED TRIAL OF A PRIMARY CARE INFORMATICS-BASED SYSTEM FOR BREAST CANCER SCREENING Steven J. Atlas 1; Jeffrey Ashburner 1; Yuchiao Chang 1; Richard Grant 1; William Lester 1; Henry Chueh 1; Michael Barry1. 1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 9052)
BACKGROUND: We sought to increase screening for breast cancer in eligible women within one primary care (PC) practice-based research network (PBRN) through a novel system of integrated population-based surveillance that linked patients to primary care providers (PCPs) and used an informatics tool to let providers review overdue patients and initiate outreach for those selected for contact.
METHODS: We randomized 12 PC practices (4 community health centers and 8 affiliated practices) to intervention (n=6) or usual care (n=6). Women 42 to 69 years of age without prior bilateral mastectomy were eligible and linked to a specific PCP or practice (if not PCP linked). Patients overdue for screening included 1) those who had not had a mammogram in the two years prior to the start of the trial (prevalent overdue) or 2) those who became two years overdue in the year after the study start date (incident overdue). In intervention practices, PCPs (for PCP-linked patients) and case managers (CMs, for practice-linked patients) received three periodic emails during the one year trial with a direct link to a web-based informatics tool that listed their overdue patients. Providers could select patients for contact or defer patients and provide a reason. Patients selected for contact received an automatically-generated letter with information about the value of screening and how to schedule a mammogram. The tool then transferred these patients to practice delegates who called patients to schedule tests or document exclusions. After the one year study period, the informatics tool remained active, though no reminder emails were sent and the original population was not updated. We

examined time to mammography completion over a 3-year follow-up period in all overdue patients and in prevalent and incident overdue populations using Kaplan-Meier curves and Cox proportional hazards regression controlling for baseline covariates and physician/practice clustering. RESULTS: Among 32,688 eligible women, baseline mammography screening rates in intervention and control groups did not differ(79.5% vs. 79.3%, p=0.73). Overall, 9795 women were overdue for mammograms including 6697 at the start of the study (prevalent overdue: 3045 in intervention and 3652 in control practices) and 3098 during the one year trial period (incident overdue: 1442 in intervention and 1656 in control practices). Intervention patients were younger, more likely to be non-Hispanic white, and have health insurance. Most intervention PCPs (59 of 64, 92%) and all CMs (6 of 6) used the tool. Action was taken in 3415 (76.1%) intervention patients (2865 [84%] contacted and 550 [16%] deferred). Over three years of follow-up, intervention patients were more likely to have a mammogram than control patients (hazard ratio: 1.19, 95% CI: 1.10-1.29, p<0.001). CONCLUSION: We developed a novel system for breast cancer screening that included a non-visit-based informatics tool for providers to screen their overdue list for contact and follow-up by practice delegates. Over three years of follow-up, intervention patients were more likely to complete mammography screening.

CO-LOCATED PRIMARY CARE IN THE MENTAL HEALTH SETTING IMPROVES ATTAINMENT OF CARDIOVASCULAR RISK GOALS IN VETERANS WITH SERIOUS MENTAL ILLNESS Emily S Rowland 1; Paul A Pirraglia 2; Peter D Friedmann 2; Thomas P OToole2. 1Alpert Medical School of Brown University, Providence, Rhode Island;
2Providence VA Medical Center/Alpert Medical School of Brown University, Providence, Rhode Island.
(Tracking ID # 9064)

BACKGROUND: Patients with serious mental illness (SMI) are at high risk for cardiovascular complications, but may not be engaged in their medical care. The benefit of co-locating general medical services into mental health settings on cardiovascular health for those with SMI has not been determined. We examined attainment of goal lipids, systolic blood pressure, and weight among veterans with SMI prior to and after enrollment in a primary care clinic co-located in mental health. METHODS: We studied veterans with SMI with prior poor primary care engagement who were then enrolled in a co-located primary care clinic for at least one year. The four six-month observation periods were (PRE1) 12 months to 6 months prior to enrollment, (PRE2) 6 months prior to enrollment until enrollment, (POST1) enrollment until 6 months after enrollment, and (POST2) 6 months to 1 year after enrollment. Based on VA practice guidelines, we defined uncontrolled cholesterol as average low density lipoprotein cholesterol (LDL) >100 if diabetes mellitus (DM) or coronary artery disease (CAD) or >130 if not, uncontrolled systolic blood pressure (SBP) as average during the observation window >140, uncontrolled weight as average body mass index (BMI) >30, and in those with DM, HbA1c >9. For each variable, unmeasured values within an observation period were considered uncontrolled. Repeated measures logistic regression tested whether control of LDL, SBP, and BMI differed across the observation periods. RESULTS: We studied 97 veterans. Mean age was 55.310.0 years;86.6% white, 8.3% black, 4.1% other race; 41.2% were service connected at 50-100%; 5% were female. SMIs included schizophrenic(23.7%), schizoaffective (24.7%), psychotic (4.1%), personality (7.2%), bipolar (14.4%), and major depressive (37.1%) disorders; these were not mutually exclusive. Medical comorbidities included DM (15.5%), hyperlipidemia (61.9%), hypertension (46.4%), and CAD (16.5%). There was a significant improvement in attainment of goal SBP (PRE1 55.7%, PRE2 52.6%, POST1 78.4%, POST2 63.9%, p<.03) and LDL (PRE124.7%, PRE2 27.8%, POST1 38.1%, POST2 65.0%, p<.0001). Improvement in BMI was borderline significant (PRE1 34.0%, PRE2 33.0%, POST1 50.5%, POST2 42.3%, p=.06). HbA1c did not appear to change. CONCLUSION: The proportion of patients at goal for SBP and LDL increased after enrollment in a primary care clinic co-located in mental health. There was little change in the two pre-enrollment periods, suggesting the change is due to enrollment in this clinic. Our findings suggest that co-located primary care improves the cardiovascular health of veterans with SMI. As patient centered

medical homes are implemented, consideration of co-located care models for vulnerable populations such as veterans with SMI is important. Future work should involve multiple sites and a contemporaneous control group.

LIKELIHOOD OF DEVELOPING DIABETES AND CARDIOVASCULAR DISEASE IN PHENOTYPICALLY OBESE METABOLICALLY NORMAL INDIVIDUALS KoKo Aung 1; Carlos Lorenzo 1; Steven Haffner2. 1University of Texas Health Science Center at San Antonio, San Antonio, Texas ; 2No institutional affiliation, San Antonio, Texas . (Tracking ID # 9070)

BACKGROUND: We previously reported that metabolically obese normal weight (MONW) individuals, despite their normal body mass index (BMI), have a higher likelihood of developing diabetes and cardiovascular disease (CVD) by the 2005 American Heart Association (AHA)/National Heart Lung and Blood Institute (NHBLI) criteria or the 2009 harmonizing the metabolic syndrome criteria. We also found that MONW individuals have a higher likelihood of developing CVD but not diabetes by the hypertriglyceridiemic waist criteria. The objective of this study is to determine the likelihood of developing diabetes and CVD in the phenotypically obese metabolically normal (POMN) individuals among the participants of the San Antonio Heart Study.

METHODS: We analyzed the data of individuals aged 25 to 64 years who did not have diabetes or CVD at the time of enrollment in the San Antonio Heart Study. A total of 1,726 participants fulfilling this criteria completed follow-up examination. We defined normal weight as BMI below 25 kg/m2 and obesity as BMI of 30 kg/m2 and above. We defined metabolically normal individuals using different standard criteria: (a) fewer than 2 metabolic abnormalities by the 2005 AHA/NHBLI criteria,(b) fewer than 2 metabolic abnormalities by the 2009 Harmonizing the Metabolic Syndrome criteria, and (c) serum triglyceride levels <2 mmol/l and waist circumference <90 cm in men and <85 cm in women by the hypertriglyceridemic waist criteria. We performed logistic regression analysis to examine the odds of developing diabetes and CVD
in POMN individuals relative to the odds in metabolically healthy and normal weight (MHNW) individuals.

RESULTS: Among the participants who fulfilled inclusion criteria, 3.8 to 18.3% met the definition of POMN, using different standard criteria. The odds ratios of developing diabetes and CVD among POMN individuals relative to MHNW individuals are as shown in the following table.

CONCLUSION: POMN individuals have a higher likelihood of developing diabetes by all three criteria. However, a higher likelihood of developing CVD is only statistically significant in participants with the hypertriglyceridemic waist criteria probably because of the lower prevalence of POMN by the AHA/NHLBI and Harmonizing criteria.

CONTRARY TO RESIDENTAND ATTENDING PERCEPTIONS, BEDSIDE CASE PRESENTATIONS DO NOT PROLONG ROUNDS Ithan D. Peltan 1;
Hang Lee 1; Douglas E. Wright1. 1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 9137)

BACKGROUND: Bedside teaching is an iconic form and key technique of medical education that many fear is on the decline. This method of instruction may be threatened further by impending work-hour limitations. We therefore studied teaching practices on a general medicine service. METHODS: At our institution, ward attending rounds occur each weekday morning and feature presentations (in the conference room, hallway, or at patients bedsides) of new patients admitted to the ward attending followed by bedside interviews and examination of patients by the team. A study investigator (IDP) visited each of our institutions five ward medicine teams daily to obtain the following information from one or more team members: number of admissions, number of bedside case presentations, and total and bedside duration of rounds. Data collection occurred in three blocks of consecutive weekdays between March and November 2010, totaling 100 observations of 15 distinct ward teams. To account for potential differences in team rounding practices

(interclass correlation) between data collection periods, we employed generalized estimating equations for multivariate regression modeling. Medicine attendings and residents were also surveyed regarding attitudes and perceptions of bedside rounds and bedside case presentations. Data were analyzed using paired or unpaired t-tests or Fishers exact test and reported as means and 95% confidence intervals.
RESULTS: Teams averaged 105 minutes (99111 minutes) on attending rounds each day and 35 minutes (3139 minutes) at the bedside (case presentations plus interviews and physical examinations). On average, teams spent 32% (29-35%) of rounds at the bedside and presented 34% (27-41%) of new ward admissions at the bedside. After linear regression, the number of ward admissions ($p<0.0001$) but not bedside case presentations ($p=0.55$) increased the total duration of attending rounds. By contrast, the number of ward admissions ($p<0.0001$) and bedside case presentations ($p =0.0004$) both correlated positively with the amount of time spent at the bedside. Surveys were completed by 60% of residents (N=107) and 65% of
attendings (N=68). Both groups estimated the percent of attending rounds spent at the bedside (39% and 37%, respectively) fairly accurately but overestimated the percent of bedside case presentations (47% and 52%, respectively). Residents ideal values for the percent of rounding time at bedside (41%) and bedside presentation (51%) were similar to perceived actual practice. By contrast, attendings wanted more time at the bedside (53%) as compared to perceived reality ($p<0.0001$) and to residents ideal ($p=0.0002$). Attendings would also prefer to present more cases at the bedside (70%) than residents ($p<0.001$) or than they themselves believe is done in reality ($p<0.0001$). While 67% of residents agreed or strongly agreed with the statement, Bedside presentations take longer than hallway or conference room presentations, only 40% of attendings shared this sentiment ($p=0.0003$). CONCLUSION: At our institution, the percent of time spent at the bedside during teaching rounds is stable or increased compared to published reports dating back 50 years. While residents are content with current practice, attendings want even more bedside rounding and bedside case presentation. Correcting the misconception that bedside case presentations prolong rounds might help accomplish that goal and, furthermore, help preserve the fraction of time being spent at the bedside on rounds in the face of tougher work-hour restrictions.

SUPPLEMENTING OFFICE-BASED CARE WITH A POPULATION-BASED DIRECT-TO-SMOKER OUTREACH INTERVENTION OFFERING FREE TREATMENT TO SMOKERS IN A COMMUNITY HEALTH CENTER: A RANDOMIZED CONTROLLED TRIAL

Nancy A. Rigotti 1;
Asaf Bitton 2; Jennifer K Kelley 3; Bettina B Hoeppner 1; Douglas E Levy 1; Elizabeth Mort1. 1Massachusetts General Hospital, Boston, Massachusetts ;
2Brigham and Womens Hospital, Brookline, Massachusetts ; 3Partners Health Care, Boston, Massachusetts .
(Tracking ID # 9139)

BACKGROUND: Tobacco remains the leading U.S. preventable cause of death. Treating tobacco use is among the most cost-effective actions in health care. Brief office-based interventions offered to all smokers are effective but clinicians do not reliably offer them. We hypothesized that

tobacco treatment use and quit rates could be increased by offering treatment directly to all smokers, apart from office visits. We tested the effectiveness of a population-based direct-to-smoker (DTS) outreach program offering free tobacco treatment to smokers in a health care system. METHODS: A randomized controlled trial of 590 smokers at 1 community health center compared usual care (n=177) to usual care plus DTS outreach (n=413). The DTS group was sent 3 monthly letters offering free phone consultation with a tobacco coordinator who offered fax-referral to the state telephone quitline and up to 8 weeks of free nicotine patches (NRT). Outcomes, assessed at 3 month follow-up, were the percent of smokers who used any tobacco treatment (counseling or meds), used NRT, used counseling, and self-reported 7-day and 30-day point prevalence tobacco abstinence.
RESULTS: 43 (10.4%) of 413 smokers in the DTS group accepted the treatment offer; 42 (98%) requested NRT

and 30 (70%) were referred to counseling. At 3-month follow-up, in an intention-to-treat analysis adjusted by logistic regression for age, sex, race, insurance, and history of diabetes and/or coronary heart disease, a higher proportion of the DTS group, compared to controls, had used NRT (11.6% vs 3.9%, OR3.47; 95%CI 1.52-7.92, p=.003), used any tobacco treatment (14.5% vs7.3%, OR 1.95, 95%CI 1.04-3.65, p=.036), and reported tobacco abstinence for the past 7 days (5.3% vs. 1.1%, OR 5.35, 95%CI 1.23-22.32, p=.026) and past 30 days (4.1% vs. 0.6%, OR 8.25, 95%CI 1.08-63.01, p=.042). The treatment offer did not increase use of counseling(1.1% vs 1.7%, p=NS) or non-NRT medication use (3.6% vs 3.9%, p=NS). Estimated marginal cost per 7-day quit at 3 months was $576. CONCLUSION: In a real-world effectiveness study, a population-based direct-to-smoker outreach offering free tobacco treatment to smokers in a community health center is a feasible, cost-effective way to increase the reach of treatment (primarily pharmacotherapy) and to increase short-term quit rates in the population.

DO ALL DIABETICS RECEIVE EQUAL CARE IN A FEDERALLY QUALIFIED HEALTH CENTER IN MICHIGAN? Manjunath Raju 1;

Venu Gourineni 1; Nephertiti Efeovbokhan 2; Keerthy Narisetty 1; Chioma Atueyi 3; Kumar Gaurav 1; Yan Xie 5; Margaret Holmes-Rovner 5;

Ade Olomu1. 1Michigan State University, Internal Medicine Residency Program, East Lansing, Michigan ; 2Michigan State University, Internal Medicine Residency, East Lansing, Michigan ; 3Michigan State University, East Lansing, Michigan . (Tracking ID # 9159)

BACKGROUND: Racial disparities in the quality of care of diabetic patients are well documented. Efforts to improve care of diabetes mellitus (DM) in Federally-Qualified Health Centers (FQHCs) in Michigan through the diabetes quality-improvement initiative may reduce differences in quality of care. FQHCs are designed to provide care for low income and medically underserved populations. Objectives:1) to determine the quality of care of DM patients 2) to determine racial differences in the care of diabetic patients in a FQHC that participated in diabetes quality-improvement.

METHODS: We carried out a retrospective study of 212 consecutive patients seen in a FQHC from January 2006 to December 2008. Patients medical records were reviewed for data regarding age, sex, race, smoking, blood pressure (BP) control (diabetics; BP <130/ 80 mmHg, non-diabetics; BPRESULTS: Of 212 patients identified, 154 had hypertension, 122 had DM, and 88 had hypertension and DM. The mean age was 53.9 +11.6 years,51.3 % were men, 74.53% had Medicaid, 11.32% had Medicare, 1.42% had private insurance and 12.74% had no insurance. We found that 117(55.19%) were whites and 95 (44.81%) were non-whites. There were no significant differences in baseline characteristics within these groups. Our results revealed a high prevalence of smoking (37.50% in whites, 36.21% in nonwhites), morbid obesity (39.29% white, 38.00 % non-whites, uncontrolled hypertension (68.75% whites, 68.97% non-whites), HbA1c >7(51.02% whites, 65.38% nonwhites), LDL <100 (50.98% whites, 40.43% non-whites), among the diabetics. There was underuse of evidence-based medication in both whites and nonwhites with no statistical significant differences between the two racial groups (see table 1).

CONCLUSION: We found no significant racial differences in the care of diabetics at the FQHC, but there was gross underutilization of evidence-based medications and poor control of blood pressure in both groups. There is an urgent need for strategies to improve diabetic care in both whites and nonwhites.

CRIMINAL CHARGES AND OUTCOMES OF PATIENTS ENTERING OFFICE-BASED BUPRENORPHINE MAINTENANCE THERAPY Elizabeth Edith Harris 1; Janet Jacapraro 2; Donald Jasinski 3; Darius Rastegar3. 1Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York ; 2Health Care for the Homeless, Baltimore, Maryland ; 3Johns Hopkins Bayview Medical Center, Baltimore, Maryland . (Tracking ID #

9163)
BACKGROUND: There is little data on the impact of office-based buprenorphine therapy on criminal activity. The goal of this study was to determine the impact of office-based buprenorphine therapy on rates of criminal charges, and to evaluate the treatment outcomes of subjects with prior criminal charges.
METHODS: We collected demographic and outcome data on 252 patients who were given at least one prescription for buprenorphine. We searched a public database of criminal charges and recorded criminal charges prior to and after enrollment. We compared the total number of criminal charges and drug charges 2 years before versus 2 years after enrollment.
RESULTS: Most (80%) of the subjects had prior criminal charges. These subjects had significantly less opioid-negative months than those without criminal charges (5.1 months vs. 6.7 months; p=0.028), and were less likely have >6 opioid-negative months (43.1% vs. 60.0%; p=0.032). However, there was no difference treatment retention at one year (55.4% vs. 52.0%; p=0.854). There was no difference in rates of criminal or drug charges 2 years before versus 2 years after enrollment, but subjects with >6 opioid-negative months had a significant decline in rates of criminal charges (0.67 vs. 0.43; p=0.031).
CONCLUSION: Prior criminal charges did not affect treatment retention in primary care office-based buprenophrine maintenance therapy, but was associated with lesser likelihood of abstinence from opioids. While the rate of criminal charges did not significantly decline, it did decline in a subset of subjects who were opioid-negative for >6 months.
WHATS THE IMPACT? CLINICAL VALIDITY AND UTILITY OF METREE, AN ELECTRONIC FAMILY HISTORY COLLECTION AND DECISION SUPPORT TOOL FOR PRIMARY CARE Lori A Orlando 1; Elizabeth R. Hauser 1; Carol Christianson 2; Karen P. Powell 3; Adam H. Buchanan 1; Astrid B. Agbaje 3; Vincent C. Henrich 3; Geoffrey Ginsburg4. 1Duke University, Durham, North Carolina ; 2University of North Carolina at Greensboro, Greensboro, North Carolina ; 3Moses Cone Health System, Greensboro, North Carolina ; 4Duke Unversity, Durham, North Carolina . (Tracking ID # 9169)
BACKGROUND: Recently, there has been a surge of interest for incorporating tools into clinical care that stratify patients into disease risk categories and personalize healthcare recommendations. The hope is that these tools will facilitate the generation of individualized health care plans that maximize health outcomes important to providers and patients and minimize harms. Much of the focus has been on new and emerging tools, but internists have long been taught that family health history (FH) collection is a crucial component in individualizing care. In fact, it has a key role in preventive healthcare, with guidelines often stratifying recommendations based upon factors that include FH. Additionally, it is critical to assessing risk for hereditary cancer syndromes; however, evidence to date indicates that there are considerable barriers to both collecting FH and using it in medical decision making. Developing a model for integrating FH into primary care (PC) and evaluating its impact on outcomes should be the first step in testing the cost-effectiveness of a stratified care approach.
METHODS: To overcome patient, provider, and system level barriers to integrating FH into PC, we took an implementation sciences approach to develop and evaluate a computerized FH collection and decision support tool, MeTree, in a clinical trial in 2 PC practices in Greensboro, NC. A third serves as a concurrent control. MeTree collects a 3 generation FH on 48 conditions with decision support for 4 pilot conditions: breast cancer, ovarian cancer, colon cancer, and thrombosis. Decision support focuses upon risk-based prevention strategies and identification of those at high risk for hereditary cancer syndromes (genetic counseling (GC) is recommended for these individuals). All adult patients scheduled for well-visits are invited to complete MeTree prior to their appointment; providers (PCPs) receive a provider report, pedigree, and tabular format FH, while patients receive a patient report and pedigree. This abstract describes a study of MeTrees clinical validity and utility. 100 consecutive patients FHs were reviewed by 1 PCP and 1 GC (gold standard), unfamiliar with MeTrees algorithms. A total of 7 PCPs and 4 GCs participated. Recommendations were scored according to the

following management categories: genetic counselor referral, at risk for hereditary cancer syndrome, breast MRI, breast cancer chemoprevention, ovarian cancer surveillance, early colorectal cancer screening, early and more frequency colorectal cancer screening, screening dictated by personal history of colon polyps, and genetic testing for inherited thrombophilia. Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) are calculated for MeTree and PCP by comparing their recommendations to the GCs. Since categories are defined by treatment recommendations, we are able to estimate clinical utility, as well. The role of variables such as physician year of graduation and patient sex, family size, and % of family members with cancer are also evaluated.
RESULTS: In the table the first 4 rows reflect operating characteristics across a disease category, while the remainder reflects those specific to a given recommendation. There are a total of 23 false positives (FP) by PCP and 27 by MeTree; and 73 false negatives (FN) by PCP and 29 by MeTree. The greatest error rates were FN GC referrals by PCP. The yellow cells highlight performance differences between MeTree and PCP, in all but ovarian cancer MeTree has the higher sensitivity, an important trait for screening tests. Of the 38 patients with PCP errors, MeTree correctly reclassifies 10 (related to GC referrals and more intense CRC screening); 28 (65%) had errors by both. When comparing characteristics of patients with errors versus those without, age (57 SD 1.5 vs 52 SD 1.7), number of relatives (23 SD 1.1 vs 20 SD 0.6), and % of family with cancer (19% SD 1.1 vs 11% SD 1.2) were all greater. These were similar regardless of whether it was MeTree or the PCP who made the error. Younger physicians (year of graduation 1995 or later) performed better (64% correct) than older ones (45% correct).
CONCLUSION: We have developed a model for integrating risk-stratification into primary care practice that begins with demonstrating the impact of a computerized family history tool, MeTree, designed to overcome established barriers in the healthcare system. Earlier data has shown that MeTree implementation is a highly positive experience for patients and providers. The data described in this abstract suggests that MeTree is a clinically valid and useful tool, performing similarly to a physician in many areas. In addition, its clinical utility is suggested by its ability to correctly reclassifying individuals who need genetic counseling, are at risk for hereditary cancer syndromes, or need more intense colon cancer screening. Since a little over one-third of the time MeTree and PCP are each able to correctly reclassify individuals missed

by the other, they appear to complement each other well. Note that this study demonstrates an ideal performance for providers as they were not forced to face logistical pressures such as time constraints and difficulties obtaining referrals. Future study will identify MeTrees impact on physician and patient behaviors and health outcomes in the real world clinical environment.
IMPACT OF CAROTID PLAQUE SCREENING ON SMOKING CESSATION AND OTHER CARDIOVASCULAR RISK FACTORS: A RANDOMIZED CONTROLLED TRIAL Nicolas Rodondi 1; Tinh-Hai Collet 2; David Nanchen 2; Karine Giraudon 2; Pascal Bovet 2; Jacques Cornuz2. 1Department of Ambulatory Care and Community Medicine, University of Lausanne, Switzerland, Lausanne, N/A;
2University of Lausanne, Lausanne, N/A. (Tracking ID # 9170)
BACKGROUND: Few randomized studies have examined the clinical impact of atherosclerosis screening on cardiovascular risk factor (CVRF) control. Smokers may be an important target group for such screening, but it is unknown whether carotid plaque screening represents a teachable moment similar to acute cardiovascular events. METHODS: We randomly assigned 536 current smokers aged 40 to 70 years to carotid plaque screening by ultrasound vs. no screening, in addition to a comprehensive smoking cessation program for all consisting of six 20-minute individual counseling sessions and nicotine replacement therapy. Smokers with at least one carotid plaque received pictures of their own plaques with a structured explanation on the significance of plaques. To ensure equal contact conditions, smokers not
undergoing ultrasound and those without plaque received an equal 7-minute explanation on tobacco risks (in

addition to counseling sessions). The primary outcome was one-week point prevalence abstinence at 1 year. Secondary outcomes were continuous smoking abstinence from quit date to 1 year, change in Framingham risk score (FRS) and control of CVRFs. Self-reported smoking cessation was confirmed by exhaled carbon monoxide and plasma cotinine concentration.
RESULTS: At baseline, participants (mean age: 51 years, 55% women) smoked an average of 20 cigarettes per day, with a median duration of smoking of 32 years. At 1 year, quit rates were high, but did not differ between the screened group and the unscreened group (point prevalence abstinence: 25.3% vs. 22.8%, p=0.51; continuous abstinence:20.8% vs. 21.0%, p=0.95). In the screened group, abstinence rates did not differ according to the presence/absence of carotid plaques. The mean absolute risk change in FRS was +0.58 in the screened group vs. +0.21 in the unscreened group (p=0.45). Control of CVRFs (low-density lipoprotein cholesterol, hemoglobin A1C (if diabetes) and blood pressure) did not differ between both groups. In multivariate analysis, point prevalence abstinence was associated with female

gender (odds ratio [OR]=1.57, 95% confidence interval [CI]: 1.02-2.42), higher age (OR=1.06 for 1 year, 1.02-1.11) and lower duration of smoking history (OR=0.95 for 1 year, 0.91-0.98).
CONCLUSION: In long-term smokers, the addition of carotid plaque screening to a smoking cessation program was not associated with increased rates of smoking cessation or better control of cardiovascular risk factors. Further studies should examine whether carotid screening would be helpful in other situations, e.g. for smokers with shorter smoking counseling or to better target preventive medications. (ClinicalTrials.gov number, NCT00548665)
IDENTIFYING PATIENTS AT INCREASED RISK FOR NOT COMPLETING PREVENTIVE CANCER SCREENING TESTS Steven J. Atlas 1; Jeffrey Ashburner 1; Richard Grant 1; Sanja Percac-Lima 1; Adrian Zai1.
1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 9207)
BACKGROUND: Electronic clinical data sources may be useful for identifying patients at increased risk for not completing preventive cancer screening tests. As part of an effort to design a population-based, patient-centric approach to comprehensive cancer screening, we developed an algorithm to identify high-risk individuals who might benefit from tailored interventions by patient navigators.
METHODS: Using outpatient claims and scheduling system data, patient registration data, and information drawn from electronic health records, we identified all eligible female patients within one practice-based research network (PBRN) who were overdue for breast, cervical, and/or colorectal cancer screening as of December 31, 2008. We developed an algorithm to assign points representing increased risk for not completing a screening test using total number of overdue screening exams (13 exams, 1 risk point for each overdue exam), language spoken (1 risk point for non-English), appointment no-show history over the prior year (1 risk point for 1 no-show visit and 2 risk points for >2 no-show visits in the prior year), and prior screening history (1 risk point for each exam >5 years overdue). We categorized patients into low (<2 risk points), moderate (3 risk points), and high (>4 risk points) risk for cancer screening non-compliance. We then followed this patient cohort over the next year (1/1/2009-12/31/2009) and compared cancer screening test completion rates by risk category using linear trend tests.
RESULTS: Among 19,565 women overdue for breast, cervical, and/or colorectal cancer screening, 15,563 (79.6%) were overdue for one screening exam, 3366 (17.2%) were overdue for two screening exams and 636 (3.3%) were overdue for three screening exams (mean: 1.24, SD: 0.50); 1654 (8.5%) did not speak English, 1957 (10.0%) had at least 1 no-show appointment in the prior year, 764 (3.9%) had >2 no-show appointments in the prior year, 6720 (34.4%) had no prior screening history for 1 exam, and 622 (3.2%) had no prior

screening history for 2 exams. Based on our algorithm, 15,138 (77.4%) were classified as low risk, 2736 (14.0%) were classified as moderate risk, and 1691 (8.6%) were classified as high risk for screening non-compliance. Screening test completion rates over the following year were 17.5% for low risk patients, 15.9% for moderate risk patients and 12.1% for high risk patients (test for trend, pCONCLUSION: Our algorithm using variables commonly available in electronic data systems was modestly effective in prospectively identifying patients at increased risk for not completing cancer screening tests. Additional efforts are needed to identify patients within primary care networks at increased risk for non-compliance.

ELIGIBLE BUT UNINSURED: PREDICTORS OF MEDICAID TAKE-UP AMONG ADULTS Benjamin Sommers 1; Meredith Roberts Tomasi 1; Katherine Swartz 1; Arnold M. Epstein1. 1Harvard School of Public Health, Boston, Massachusetts. (Tracking ID # 9216)

BACKGROUND: Millions of Americans are eligible for public insurance coverage through Medicaid, yet are currently uninsured. The importance of solving the puzzle of why they are eligible but not enrolled is heightened by the passage of the Affordable Care Act, which will expand Medicaid eligibility in 2014 to non-elderly adults with incomes up to 133% of the Federal Poverty Level. For the impending Medicaid expansion to be effective in improving health care access and health outcomes among low-income Americans, we need to know what factors determine whether eligible individuals actually enroll.

METHODS: Our data come from two sources the Current Population Surveys (CPS) Annual Social and Economic Supplement (20052010), and a primary dataset of state-level eligibility policies assembled from previous research. Using state and year-specific eligibility criteria, we estimated Medicaid take-up rates among eligible U.S. citizens aged 1964, who have no other form of health insurance (n=36,013). Estimates were adjusted for underreporting of coverage in the CPS. We tested for statistical differences across states and years using survey-weighted chi-square tests. We used multivariate logistic regression to identify predictors of participation in Medicaid and then to generate adjusted predicted probabilities of enrollment for each variable. Covariates were demographic variables such as age, gender, and race/ethnicity; self-reported health status; state of residence; and category of eligibility (disabled, parent of dependent children, or non-disabled non-parent).

RESULTS: Nationally, among Medicaid-eligible adults with no other form of health insurance, 62.2% were enrolled in Medicaid (95% Confidence Interval 61.4-63.0%), leaving 37.8% who were uninsured. There was no significant time trend in take-up rates from 20052010, though the total number of eligible adults rose significantly in 2009 2010. Take-up rates varied significantly across states (p=0.001), and these differences remained large even after multivariate adjustment for population characteristics, with predicted enrollment rates ranging from 39.9% in Arkansas and 41.6% in Louisiana to 75.2% in Maine and78.3% in Massachusetts. In terms of individual characteristics, Medicaid participation was most likely among disabled adults (adjusted predicted probability 72.1%), less likely among parents of dependent children (53.2%), and least likely among non-disabled childless adults(40.3%; group difference p=0.001). Participation was higher among adults with fair or poor self-reported health status than those with excellent health (63.3% vs. 54.8%, p=0.001). Racial differences existed as well, with take-up highest among blacks (62.7%) and lowest among whites (57.8%, p=0.001). Take-up was higher among younger adults, single adults, those with less education, and women.

CONCLUSION: Millions of adults who are currently eligible for Medicaid remain uninsured. There is great variability in take-up rates across states that exceeds the variation from individual-level factors such as

race and health status. Participation is particularly low among healthy adults without disabilities and without children, who comprise the majority of the individuals who will become newly eligible for Medicaid under the Affordable Care Act. The success of the impending Medicaid expansion under health reform will depend on states ability to design approaches that achieve high participation rates among newly-eligible adults.

HEAT RELATED DEATHS IN THE STATE OF ARIZONA: IDENTIFYING AT-RISK INDIVIDUALS Emily

Shortridge 1; Sandipan Pati1.
1St. Josephs Hospital, Phoenix, Arizona . (Tracking ID # 9225)
BACKGROUND: Summer heat waves are among the deadliest environmental events, and are a serious fatality risk in the state of Arizona. Normal daily maximum temperatures in Phoenix, Arizona can exceed 100Ffrom June through mid-September. Medical, social and environmental risk factors for heat-related mortality may be different between different demographic populations. The primary aim of this study is to identify differences in medical co morbidity, demographics, and other risk factors among individuals who died following exposure to heat in the state of Arizona. The results of this study help in identifying at-risk individuals who are potential targets for preventive strategies. METHODS: The target population for the study comprised individuals who had died following exposure to heat in the state of Arizona between 2002 and 2009. Data were collected from the Arizona Department of Health Services, Health Status and Vital Statistics Section. Statistical analysis was performed with SPSS 18.0. Exposure to excessive natural heat as the underlying cause of death is identified by a three-character category X 30as defined in ICD-10.
RESULTS: 975 people died following exposure to heat in last 8 years in the state of Arizona. Among the 975, 718(73%) were male. The racial composition is as follows: non-Hispanic white 164(64%), Hispanic/ Latino 561 (57%), black 27 (3%), Native American 28 (3%) and unknown race 192 (19%). Age at death was classified in 4 different groups as follows: 125 years (N=188; 21%), 26-45 years (N=346; 39%), 4665 years (N=232; 27%); greater than 66 years (N=125; 15%). Victims of heat related death were divided into three subgroups, with risk factors varying markedly between groups: Individuals attempting illegal transit across the Mexico-U.S. border, Arizona residents, and visitors to Arizona from other U.S. States or Canada for duration less than 1 year. Individuals in transit across the border accounted for the majority of the total death count at 45%. Residents comprised 29%and visitors 16%. Major risk factors for the immigrant population were dehydration and polysubstance abuse, with an unknown cause for many deaths. Risk factors for Arizona residents were polysubstance abuse, dehydration, medical co morbidity, and advanced age. The primary risk factor for visitor death was dehydration. Age at time of death was heavily subgroup-dependent, with 71% of the in-transit population fairly young, 2044 years old, at time of death. Risk factors among young and elderly residents were vastly different, with drug abuse, ethanol toxicity, and hiking contributing to deaths under age 45, and cardiovascular disease, dementia, and other neurodegenerative disease contributing to deaths over age 65.
CONCLUSION: Risk factors associated with death following heat exposure are different between individuals of different age, sex, and
residency status. Clinically, these risk factors can be used to identify most at-risk individuals, as well as probably etiologic contributors to a patients acute heat related illness.

PERSPECTIVES ON PREVENTIVE HEALTH CARE AND BARRIERS TO BREAST CANCER SCREENING AMONG IRAQI WOMEN REFUGEES Altaf Saadi 1; Barbara Bond 2; Sanja Percac-Lima2.
1Harvard Medical School, Boston, Massachusetts; 2Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 9238)
BACKGROUND: Since the Iraq war began in 2003, over four million Iraqis have been displaced with 13,800 Iraqi refugees admitted to the US in 2008. Little is known about preventive cancer care in this population. We identified disparities in mammography rates in eligible Arabic speaking patients (44%) compared to over 80% in English or Spanish speaking women. The majority of Arabic speaking women were refugees from Iraq. We sought to assess their perspectives on preventive care and perceived barriers to breast cancer screening.
METHODS: Patients were identified from data collected at the Massachusetts General Hospital Chelsea HealthCare Center, an urban community health center in a predominantly low-income, immigrant community. In-depth, semi-structured, one-on-one interviews were conducted with twenty Iraqi refugee women by a bilingual (English/ Arabic) medical student. Interviews were performed in Arabic, transcribed, translated and coded according to established qualitative content and thematic analysis procedures.

RESULTS: The women were on average 43 years old (range 2375). Psychosocial barriers identified included fear of pain associated with obtaining a mammogram and fear associated with receiving a cancer diagnosis. Culturally mediated beliefs that define illness as symptomatic and that do not incorporate the idea of preventive care were identified. Though modesty issues were mentioned, they were not felt to be the most significant barrier. Although some women had never heard of mammography, the majority were aware of it but believed it was necessary only when there was something wrong with the breast. Many mentioned that receiving screening was not the norm in their home countries, but they did have a heightened awareness of breast cancer, citing rising prevalence of cancer in Iraq due to the consequences of biological and chemical warfare. In addition to fear, another theme related to the health consequences of war that make day-to-day survival supersede all other concerns for these women. As one woman said: (Iraqis) are living in conditions that has (sic) forced them to forget about their own lives. Here, no. An individual will pay attention to his health more to his food, to his health, to his sleep all these things, here, you have the luxury to pay attention to. Most women spoke positively about the outreach, attention and reminders received from the health center and felt it encouraged them to follow up with appointments.
CONCLUSION: We identified factors that may impede Iraqi refugee womens ability and motivation to obtain breast cancer screening including not having experienced screening as normative in their home country, the belief that preventing disease is not the function of doctors and medicine, and psychosocial concerns such as fear of pain and fear of cancer, as well as consequences of the war. Women expressed interest

in education and outreach to help them obtain screening mammography and support community-based culturally appropriate health education and outreach programs.
ACCULTURATION AND CARDIOVASCULAR BEHAVIORS AMONG LATINO SUB-GROUPS Andrew J. Van Wieren 1; Mary B. Roberts 2; Naira Arellano 3; Edward Feller 4; Joseph Diaz5. 1Alpert Medical School of Brown University, Providence, Rhode Island ; 2Brown University/ Memorial Hospital of Rhode Island, Pawtucket, Rhode Island ; 3Injury Prevention Center at Rhode Island Hospital, Providence, Rhode Island ; 4Department of Community Health, Brown University, Providence, Rhode Island ; 5Brown University/Memorial Hospital of Rhode Island, Pawtucket, Rhode Island . (Tracking ID # 9241)
BACKGROUND: Latinos are expected to increase from 15.5 to 25% of the US population by 2050, and represent nearly 20 countries. Despite lower socioeconomic status and worse access to health care, Latinos have better overall health outcomes and longer life expectancy than non-Latino Whites. This Latino Health Paradox has been partially attributed to healthier cardiovascular (CV) behaviors among Latinos. However, as Latinos become more acculturated or Americanized, differences in some CV behaviors disappear. Despite diversity among Latinos, few studies have examined the role of country of origin in impacting associations between acculturation and CV behaviors among Latinos.
METHODS: Data from the 2005 and 2007 California Health Interview Survey (CHIS) were used to measure associations between acculturation level and smoking, diet and physical activity patterns among Latino sub-groups. To measure acculturation, we utilized a previously validated scale to categorize Latinos as low, moderate or high acculturation based on language, citizenship, birthplace and percent of life spent in the US. Using non-Latino Whites as a reference group and controlling for demographic variables, we calculated adjusted odds ratios (ORs) by acculturation level and country of origin for: never smoking, meeting American College of Sports Medicine (ACSM) physical activity and 5-a-day fruit/vegetable recommendations, and consuming any daily fast food.
RESULTS: The sample included 16,000 Latinos and 60,638 non-Latino Whites. Measured demographic variables were statistically different ($p<0.0001$) between acculturation groups. Among all Latinos, adjusted ORs

(with 95% CIs) of never smoking were 2.73 (2.43-3.08), 2.40 (2.18-2.64), and 1.35 (1.23-1.49) for the low, moderate and high acculturation groups, respectively. We found no significant differences by acculturation level for the odds of meeting either ACMS physical activity guidelines or 5-a-day fruit/vegetable recommendations among all Latinos. Adjusted ORs of consuming any daily fast food were 0.74(0.63-0.88), 1.35 (1.17-1.56), and 1.69 (1.48-1.93) for the low, moderate and high acculturation groups among all Latinos. These trends varied considerably by country of origin, however. Guatemalans, the subgroup skewed most toward low acculturation level (55.9%), showed the strongest association between increased acculturation and higher smoking rates and were the only sub-group with an increase in physical activity, but showed no association between acculturation and fast food consumption. Conversely, South Americansa group of predominantly moderate acculturation (59.3%)had high baseline smoking rates and reduced smoking with increased acculturation. Puerto Ricans, the sub-
group skewed most toward high acculturation level (75.4%), showed the strongest association between increased acculturation and higher fast food consumption.
CONCLUSION: As the US Latino population expands dramatically, the Latino Health Paradox will become increasingly important to public health. Our results indicate that country of origin impacts associations between acculturation and CV behaviors in complex ways, a finding that has implications for clinical practice and further research. Clinicians should consider both acculturation and country of origin when counseling Latino patients about CV risk to maximize cultural sensitivity and effectiveness. Although CHIS data lack generalizability to the overall Latino population, this study contributes to the limited literature on this topic and demonstrates need for further research.

UPTAKE OF AN INTERNET-BASED PATIENT PORTAL AND ETHNIC AND EDUCATIONAL DISPARITIES: THE DIABETES STUDY OF NORTHERN CALIFORNIA (DISTANCE) Urmimala Sarkar 1; Andrew Karter 2; Jennifer Liu 2; Nancy Adler 1; Robert Nguyen 2; Andrea Lopez 3; Dean Schillinger1. 1University of California, San Francisco, San Francisco, California ; 2Kaiser Permanente, Oakland, California ;
3University of California San Francisco, San Francisco, California . (Tracking ID # 9254)

BACKGROUND: Internet-based patient portals, which allow patients to access their health care system and perform selected self-management functions, will play a growing role in chronic disease care. By increasing health access, this technology has potential to ameliorate diabetes disparities, if widely used in vulnerable groups. Prior research has demonstrated that ethnically diverse, low-income patients are amenable to technologically-delivered chronic disease self-management support. However, the same populations with worse diabetes outcomes are subject to the digital divide, a lack of adequate computer/ internet access; thus, the diffusion of this innovation may actually widen disparities, as seen with prior health advances.
METHODS: We investigated uptake of an internet-based patient portal by race/ethnicity and educational attainment between January 2006 and December 2009, among an English-speaking adult, continuously insured population with diabetes receiving care in an integrated health maintenance organization. We measured the frequency of requesting a password for the patient portal, which represents intent to use the patient portal and indicates some computer access.
RESULTS: We studied 11,921 participants: 10% with less than high school education, 29% high school graduates, 27% some college, and 35% with college degree or higher educational attainment. They were ethnically diverse (27% non-Hispanic White, 13% Latino, 21% African-American, 10% Asian, 12% Filipino, 17% multi-racial/other ethnicity). Overall, intent to use the patient portal (i.e. requesting a password) increased markedly over the observation period across all educational levels and race/ethnicities, from 1,427 (12%) of participants in 2006 to 4,466 (37%) in 2009 (Figure A and B). In addition, the rate of uptake, or increase in registration over time, did not vary by educational attainment or race/ethnicity (p=0.47 and 0.66, respectively) The initial modest-sized educational gradient in intent to use the patient portal widened slightly in absolute terms by 2009, but attenuated in relative terms (Figure Panel A). In 2006, 9% of those with less than a high school

degree

requested a password, compared to 13% of those with a college degree or higher (p <0.001). In 2009, 32% with less than a high school degree had requested a password compared to 39% with a college degree or more (p<0.001). Similarly, in 2006, there were small race/ethnic differences in intent to use the patient portal, with African-American, Filipino and Latino participants least likely and Asian and White participants most likely to request a password (Figure Panel B). Relative differences narrowed over time, for all ethnic groups. Absolute differences also narrowed, except among African Americans: in 2009, Whites were most likely and African-Americans least likely to request a password (40% vs. 34%, p<0.001). CONCLUSION: We observed rapid, widespread uptake in use of the patient portal among diverse, English-speaking adults with diabetes. Those with lower educational attainment and African-Americans remained consistently less likely to register for the patient portal at each time-point, lagging in uptake by about 1 year. Expanded computer/ internet access, training in patient portal use and cultural/ educational tailoring may be required for patient-facing electronic health records to be harnessed as a means to reduce disparities.

OUTCOMES OF PREOPERATIVE EVALUATION IN PATIENTS UNDERGOING HIP FRACTURE SURGERY Geetha Selvakumar 1; Ayesha Salahuddin 1; Meghana Gopal 1; Mahvesh Mahmud 2; Muhammed Sherid 4; Habib Dakkak 4; Nael Gharbi 4; Shazel Gharbi 4; Mhd. Wisam Baqdunes 4; Harvey Friedman4. 1Saint Francis Hospital, Evanston, Illinois; 2St.Francis Hospital, Evanston, Illinois. (Tracking ID # 9257)

BACKGROUND: Preoperative evaluation in selected patients undergoing hip fracture surgery prevents complications like MI and sudden cardiac death during the postoperative period. Orthopedic surgeries are considered as intermediate risk surgeries for the development of cardiac complications. The reported cardiac risk is generally less than five percent. Patients without major risk factors with excellent functional capacity can undergo intermediate risk surgeries without any cardiac work up with little likelihood of perioperative cardiac complications. We stratified patients
undergoing hip fracture surgery over a period of one year into high, intermediate and low risk groups and analyzed the outcomes of unnecessary preoperative cardiac work up in the low risk group.

METHODS: Retrospective chart review of all admissions for hip fractures during the year 2007 was done. A total of one hundred and twenty one charts were reviewed. The study was approved by the institutional review board. Nine patients (7.44%) belonged to the high risk group, sixty nine (57.02%) to the intermediate risk group and forty three (35.54%) to the low risk group. The following work up was done in the low risk group: echocardiogram in twenty one (48.84%), stress test in seven (16.28%), medicine consults in twenty (46.51%) and cardiology consult in ten patients (23.26%). RESULTS: The results showed that an average of 38.60% patients in the low risk group received preoperative cardiac work up. Surgery was delayed by four days due to unnecessary work up in this group.

CONCLUSION: Orthopedic surgeries in low risk patients can safely be performed without preoperative cardiac work up. Unnecessary work up in the form of echocardiogram, stress test and medicine and cardiac consults in addition to causing financial burden increase the length of hospital stay further causing an increase in healthcare cost. Adhering to the ACC/AHA guidelines for perioperative cardiac risk assessment for noncardiac surgeries will help to reduce healthcare costs and improve patient satisfaction.

SIGNAL AND NOISE: APPLYING AN AUTOMATED TRIGGER TOOL TO SCREEN FOR ADVERSE DRUG EVENTS IN THE SETTING OF OUTPATIENT CHRONIC DISEASE CARE Stacey Brenner 1; Alissa Detz 2; Claire Horton 3; Andrea Lopez 3; Nancy Jianhua Jin 1; Urmimala Sarkar1. 1University of California San Francisco, San Francisco, California ; 2California Pacific Medical Center, San Francisco, California ;

3University of California, San Francisco, San Francisco, California . (Tracking ID # 9263)
BACKGROUND: The extent of outpatient adverse drug events (ADEs) remains unclear. Information about ADEs is limited by our ability to detect and monitor these events. Trigger tools are used as a screening method to identify care episodes that may be adverse drug events, but their value in a population with a high chronic-illness burden remains unclear. We sought to determine if a six-item trigger tool would successfully identify ADEs in among a chronically ill patient population.
METHODS: We used 6 abnormal laboratory values (internationalnormalized ratio (INR) >5, serum creatinine (SCr) >2.5, blood urea nitrogen (BUN) >60, alanine aminotransferase (ALT) >84, aspartate amino-transferase (AST) >80,thyroid-stimulating hormone (TSH) undetectable while on levo-thyroxine) because they have been shown to have a high positive predictive value for detecting ADEs among older adults in outpatient care, but have not been tested in a safety net population with high burden of chronic illness. Eligible patients were included if they were >18, sought primary or urgent care within the study period (November 2008-November 2009)and were prescribed at least one medication. We then used the clinical/ administrative database to identity patients with these triggers. Two physicians conducted in-depth chart review of any medical records with identified triggers. The physicians determined 1) whether an adverse drug event did occur, 2) the stage of the medication process where the event occurred, and 3) the severity of the effect on the patient. Physician reached an inter-rate agreement of 94%.
RESULTS: We reviewed 782 triggers representing 583 patients. The mean patient age was 55 (14), 64% were male, 70% were English-speaking. The trigger tool identified 109 (14%) adverse drug events. We identified 18 ADEs that took place in the inpatient setting that were omitted from further analysis. Of the 91 ADEs included in our analysis, 49 (54%) occurred during medication monitoring, 41 (45%) during patient-self administration, and the other could not be determined. 90% posed minimal or mild harm to the patient, 8% posed moderate harm or severe harm and 1 (1%) could not be determined. 96% of abnormal INR triggers were adverse drug events, followed by 12% of abnormal BUN triggers, 9% of abnormal ALT triggers, 8% of abnormal SCr triggers, and 3% of AST triggers. CONCLUSION: When we employed an ADE screening trigger tool in a safety-net primary care clinic with a high prevalence of chronic illness, the yield was less than in the healthier population originally studied. Moreover, utility varied significantly among the 6 triggers.
While the INR >5successfully identified ADEs, concomitant chronic disease lowered the yield for other abnormal-laboratory-value triggers. Our findings imply that other tools, such as text triggers, or more complex automated screening rules which combine data hierarchically, are needed to effectively screen for ADEs in chronically ill adults seen in primary care.
FACTORS CONTRIBUTING TO OUTPATIENT DIAGNOSTIC DELAYS: A QUALITATIVE ANALYSIS OF PHYSICIAN PERSPECTIVES Urmimala Sarkar 1; Brett Simchowitz 1; Doug Bonacum 2; William Strull 3; Andrea Lopez 1; Leahora Rotteau 3; Kaveh Shojania6. 1University of California, San Francisco, San Francisco, California ; 2Kaiser Permanente, Oakland, California ; 3University of Toronto, Toronto, Ontario . (Tracking ID # 9264)
BACKGROUND: Delayed and missed diagnoses lead to significant patient harm and health care costs. The prevalence and consequence of diagnostic error remains unclear, and the complexity of the outpatient diagnostic process has left this important aspect of patient safety relatively under-studied. We analyzed transcripts from physician focus groups to understand failures in the diagnostic process.
METHODS: As part of a quality improvement initiative an integrated health system conducted physician focus groups in 2004 and 2005. Regional leadership decided whether to participate in the project, and within the three participating regions, physicians were invited to participate in focus groups via a mailed letter and email. Both primary care and subspecialty providers were included in focus groups, by design, to address the breadth of the diagnostic process. The focus groups included questions about the process of diagnosis, specific factors contributing to missed diagnosis, use of guidelines, atypical vs. typical presentations of disease, diagnostic

tools, and follow-up all with regards to delays in the diagnostic process. Focus groups were audio-taped and transcribed verbatim, and subsequently de-identified. Two investigators (BS, US) read through all six transcripts and assembled a coding scheme and a list of codes. Two investigators (BS and AL) blindly reviewed 2 transcripts achieving an inter-rater reliability score of 0.81. The rest of the transcripts were coded by one investigator (BS).
RESULTS: Six focus groups were conducted with 37 participants representing 30 physicians. A number of themes were identified that described clinicians perceptions of diagnostic delay, difficulty, and mis-diagnosis (Table). These were (1) concerns about the organization of the health system, including information availability and work flow/ processes involved in ordering diagnostic tests; (2) the effect of interactions amongst providers, including communication and shared responsibility; (3) the importance of the patients role in the diagnostic process, including factors such as language barriers and non-adherence; (4)physician characteristics affecting the diagnostic process, including cognitive factors and interpersonal responsiveness and (5) the intrinsic variability of disease presentation.
CONCLUSION: Organizational factors, interactions among health care providers, patient characteristics, provider attributes, and the intrinsic variability of disease presentation, all contribute to missed and delayed diagnosis in this focus-group study of ambulatory providers practicing in an integrated care system. In order to improve the diagnostic process, multi-modal interventions that address organizational factors, physician education and work flow, and patient barriers, are needed.

THE MANAGUA CARDIOVASCULAR HEALTH INITIATIVE: A COMMUNITY HEALTH WORKER INTERVENTION TO IDENTIFY AND MANAGE HYPERTENSION IN URBAN NICARAGUA
Christopher Michael Dodd 1; Victor Giancarlo Sal y Rosas Celi 2; Saul Contreras Martinez 3; Joshua Chen 4; Sheyla Zelaya 5; James LoGerfo 2; Thomas Gaziano 6; Stephen Symes 7; Olveen Carrasquillo8. 1Jay Weiss Center, Shoreline, Washington; 2University of Washington School of Medicine, Seattle, Washington; 3Atencion Primaria en Salud, Managua, N/A; 4Boston University School of Medicine, Boston, Massachusetts; 5University of Miami Leonard M. Miller School of Medicine, Miami, Florida; 6Harvard University School of Medicine, Boston, Massachusetts; 7University of Miami Leonard M. School of Medicine, Florida, Florida; 8University of Miami Leonard M. School of Medicine, Miami, Florida. (Tracking ID # 9272)
BACKGROUND: Chronic illnesses are emerging as the leading cause of death in developing countries. In Nicaragua the prevalence of hyper-tension (HTN) is 25% and poorly controlled. HTN is a major public health problem. Community health workers (CHW) are robust components of their health system but are primarily deployed to address infectious illnesses and maternal child health issues. In this feasibility study we determine if CHWs can 1) identify community patients with uncontrolled HTN, and 2) help address the emerging crisis of cardiovascular disease in this resource-limited country.
METHODS: We recruited 32 CHWs from a health district in Managua of 110,000 residents, of whom 50% are unemployed. After a comprehensive training, CHWs used standardized protocols and an automated BP device to do home screening in their local community. As part of our agreement with the leadership of the local health district, CHWs would also be assigned medically indigent patients treated at the local health centers or hospital with a diagnosis of hypertension crisis and in need of outpatient community follow-up.
To test the feasibility of our proposed intervention, we planned to enroll 32 patients from both referrals sources. The CHW intervention consisted of a 10 day period of home health education, assistance navigating the health system, assistance obtaining prescribed medications, and when needed, directly observed therapy. The primary outcome was change in systolic blood pressure from baseline to a measurement taken 2 months later. Although this was primarily a pilot feasibility study, we used a two-sample t-test to determine if any observed changes were statistically significant. RESULTS: During a one-week period, our CHWs screened 185 individuals. The

mean age was 49 years and 78% were female. Of these, 42% had BP >=140/90 on 2 consecutive visits and 17% had BP >=160/100. Over 90% were aware of their diagnosis, but only 70% we taking medications. For the intervention, 31 patients were selected; 12 identified by home screenings and 19 from health facility referrals. At two months we found a median decrease of 11 mmHg in SBP in these 31 patients (P=0.052). CHWs noted that at baseline most patients had poor understanding of hypertension, low adherence to lifestyle modification, and most needed assistance in obtaining medications.
CONCLUSION: We recruited and trained 32 CHWs who in one week identified 117 persons with uncontrolled BP. We showed our CHWs intervention has the potential to improve BP in this resource limited setting. The findings from this feasibility study support the need for a larger RCT.

MEDICAL STUDENT ATTITUDES TOWARDS FINANCIAL INCENTIVES IN HEALTHCARE SETTINGS April Barbour 1; Elizabeth Gray1.
1George Washington University, Washington, District of Columbia. (Tracking ID # 9276)
BACKGROUND: In an era of pay-for-performance, there has been recent interest in the impact that financial incentives play in healthcare decision-making. The AAMC and other professional societies have outlined a large body of work which debate the ethics and consequences of these types of secondary interests. No study to date has assessed whether students in their formal years of training have had any exposure to these issues or performed an assessment of their underlying attitudes towards these incentives.
METHODS: All medical students on rotation in Internal Medicine at George Washington University Hospital were invited to a 30 minute program on the impact of financial incentives in healthcare. Before the talk, a questionnaire was provided to assess baseline attitudes. These data were de-identified and aggregated for further statistical analysis. A multivariate regression analysis was done to compare the relative contribution of the student characteristics and their correlation with the survey data.
RESULTS: Less than half of the students surveyed had ever attended a class on the impact of financial incentives in healthcare. All students felt that physicians were influenced by financial pressures, and all agreed that other students were influenced in their choice of careers by salary. The students were divided on the influences of finances on their own careers. Most were unsure of that physicians should be able to invest in pharmaceutical or medical device companies. Most were also unsure of the role that financial disclosures in either patient care settings or in the evaluation of research journals.
CONCLUSION: Medical students consistently under-value the impact of financial incentives in healthcare settings. With the push towards pay for performance, the enacting of rules requiring financial disclosures in patient care, and in the evaluation of medical research, more educational opportunities should be created for medical students to be exposed to and discuss these important topics.
CALCIUM SUPPLEMENTS RAISING THE RISK OF MYOCARDIAL INFARCTION: IS THE RISK CLINICALLY SIGNIFICANT? KoKo Aung 1;
Thwe Htay1. 1University of Texas Health Science Center at San Antonio, San Antonio, Texas. (Tracking ID # 9278)
BACKGROUND: Much publicity has been given to the finding in a recent meta-analysis that individuals who took calcium supplements (without coadministered vitamin D) are associated with 27% more myocardial infarctions than those who did not. One of the limitations of conventional frequentist statistics is that even when statistically significant change of outcome is detected, we may still know little about its clinical significance. In such circumstances, Bayesian analysis provides a useful interpretation by setting the findings in the context of cautious and enthusiastic prior beliefs. The objective of this study is to determine whether calcium supplements increase the risk of myocardial infarction and cardiovascular events at the clinically significant level.

METHODS: We analyzed the data from meta-analysis using a formal quantitative algorithm using Bayes theorem. The outcome measures were myocardial infarction, stroke, composite outcome (combined myocardial infarction, stroke and sudden death) and death. We defined clinical significance as the probability of smallest clinically harmful
values of the effect. We set various thresholds for clinical significance as relative risk increase of 1%, 10%, 20%, and 27% for each outcome. We estimated the probabilities of clinically significant increased risk for each outcome from posterior probabilities for skeptical and enthusiastic priors in Bayesian model. Statistical analyses were performed using BayesLine 9.1, version 010108 (Diamond &Kaul, Los Angeles, CA). RESULTS: In the context of skeptical or cautious prior belief of calcium supplements increasing cardiovascular risk, the probabilities of 10% relative risk increase are 35%, 17%, 23% and 9% for myocardial infarction, stroke, composite outcome (myocardial infarction, stroke or sudden death) and death respectively. In the context of enthusiastic prior belief of calcium supplements increasing cardiovascular risk, the probabilities of 10% relative risk increase are 75%, 51%, 54% and 27% respectively. When the threshold of clinical significance was raised to 20% relative risk increase, the corresponding probabilities became 27%, 5%, 3% and less than 1% for skeptical prior and 54%, 15%, 9% and less than 1% for enthusiastic prior. The probability of 27% relative risk increase in myocardial infarction, as estimated by frequentist statistical methods in the original meta-analysis, is only 12% in the context of skeptical prior belief and 27% in that of enthusiastic prior belief. CONCLUSION: There is a reasonable suspicion of calcium supplements (without coadministered vitamin D) increasing the relative risk of myocardial infarction by at least 10-20%, stroke by at least 10% and combined myocardial infarction, stroke or death by at least 10%. There is insufficient evidence of calcium supplements (without coadministered vitamin D) increasing the relative risk of death by at least 10% or increasing the relative risk of myocardial infarction by at least 27%. Reassessment of the role of calcium supplements in prevention and treatment of osteoporosis is warranted. On a broader note, we would encourage a wider use of Bayesian methods in reports of clinical research to integrate statistical significance and clinical significance.

EFFECTS OF AN AUTOMATED ELECTRONIC REMINDER IN IMPROVING DIABETES CARE QUALITY IMPROVEMENT Thwe Htay 1;

Marijan Gillard2. 1University of Texas Health Science Center at San Antonio, San Antonio, Texas ; 2University of Texas health Science Center at San Antonio, San Antonio, Texas . (Tracking ID # 9285)

BACKGROUND: The rates of periodic hemoglobin A1c (HbA1c) and urine microalbumin testing, which are considered standard quality indicators for diabetic patients, were relative low in internal medicine and family practice clinics of an academic health center. The aim of this quality improvement project is to increase the HbA1c and urine microalbumin testing rates in diabetic patients in the internal medicine and family practice clinics using a computerized reminder system of the electronic medical records.

METHODS: Overall improvement plan was to increase relative testing rates of HbA1c and urine microalbumin testing rates by using a computerized reminder system. Proposed change was implemented by educating all key stakeholders including faculty physicians, clinic administrative personnel, clinic nurses and medical assistants about the purpose of the project and methods of implementation during weekly meetings and by sending e-mails to the physicians describing the details related to the project. The change was anticipated within 10 weeks after initiation of the alert system. This is the first pilot quality project using a computerized reminder system of electronic medical records in our institution.

RESULTS: There was an absolute mean difference of 15.5% and 24.7% increase in HbA1c and microalbumin testing rates after implementation

of the intervention (p=0.02 for HbA1c; p=0.0001 for microalbumin). This represents a relative increase of 40% in HbA1c testing rate and 226% in urine microalbumin testing rate after initiation of computerized reminder system. The return on investment for the computerized reminder system includes cumulative savings for

physician time, cumulative reduction in operational expenses by reducing the need of support staff to manually tract the tests and potential increase in patient care revenues. CONCLUSION: Computerized reminder system through electronic medical records improved HbA1c and urine microalbumin testing in outpatient setting. Integrating computerized reminder alert system to routine outpatient care in diabetes population not only improves the quality of care but also saves the manpower utilization by saving the time spent by physicians and support staff in tracking previous test results and determining when the tests are due.

HOMEBOUND: ACUTE CARE USE AND HEALTH CHARACTERISTICS FOR A COHORT OF CHRONICALLY ILL ELDERLY

Kristofer L Smith 1;
Ania Wajnberg 1; David Russell 2; Joseph S Ross 3; Alex Federman1.
1Mount Sinai School of Medicine, New York, New York ; 2Visiting Nurse Service of New York, New York, New York ; 3Yale School of Medicine, New Haven, Connecticut . (Tracking ID # 9307)

BACKGROUND: Over three million community-dwelling seniors have functional impairments that leave them homebound and limit their access to routine healthcare services. Functional impairments, along with poor health status, tenuous socioeconomic status, and relative difficulty accessing outpatient care, likely increase emergency department (ED) visits and hospital admissions. We conducted a study of homebound older adults to characterize their health status, functional dependence, and quality of life, as well as recent acute care usage. METHODS: We recruited homebound patients newly enrolled in two home-based care programs, the Mount Sinai Visiting Doctors (MSVD) program and the Visiting Nurse Service of New York Long-term Home Health Care Program (Lombardi). We included patients age >65 years who were English or Spanish speaking and were able to provide written consent or had a proxy to provide consent. Homebound status, extrapolated from the Medicare guideline, was defined as leaving the home infrequently and requiring assistance when leaving the home. We first characterized homebound patients with respect to number of dependencies in activities of daily living (ADL) and instrumental activities of daily living (IADL), Quality of Life in Alzheimers Disease Scale (QoL-AD), General Health Status (SF-1), and Cornell Scale for Depression (CSD). In addition, we collected self-reported visits to primary care physicians (PCP), specialist physicians, and the ED, as well as hospitalizations within the 3 months prior to MSVD or Lombardi enrollment. Finally, we examined bivariate associations between patient demographic and health characteristics and hospitalizations or ED visits. RESULTS: We recruited 65 patients; the majority was over 80 years of age (51%) and female (86%). Approximately a third were white (39%), black (37%), and Latino (35%). Forty (62%) had household income <$1000/month, 33 (51%) had received some high school education or less, and all had a home attendant or aide. The mean number of ADLs and IADLs requiring assistance was 4.1 (STD 2.2) and 5.7 (STD 1.8) respectively. For health related quality of life the mean score was 31.4 (STD 6.8) on the QoL-AD (range from 13 [least quality] to 53 [highest quality]). Patient reported a mean health status score of 3.6 (STD 1.1) on the SF-1. CSD mean score was 11.7 (STD 7.3) and 32 (49%) met criteria for probably major depression (score >10). In the three months prior to program enrollment, 32 (51%) had more than one PCP visit and 29 (47%) had visited a specialist more than once. During those three months, rates of acute care use were high: 33 (51%) reported making a
visit to the ED and 30 (46%) were hospitalized. In bivariate analysis, greater ADL impairment was associated with greater likelihood of hospitalization (4.7 mean ADLs impaired for hospitalized patients vs.3.6 mean ADL impairment for non-hospitalized patients p=.05). There was no association between age, gender, race, income, household support, PCP involvement, depression, general health status, or quality of life on either ED visits or hospitalizations.

CONCLUSION: Homebound older adults in this study have substantial physical limitations, depression, and experience high rates of acute care use. Except for increased ADL dependence, our analysisfocused on explanatory variables shown in other elderly populations to be correlated with acute care usagedid not reveal any associations. The homebound reflect a growing group of chronically medically ill elderly. To better care for

these patients and control rising costs, understanding how to prevent them from utilizing acute care services will be a health policy priority.

GROUP MEDICAL VISITS FOR ALZHEIMERS DEMENTIA PATIENTS AND THEIR CAREGIVERS Gina Fujikami 1; Steve Lai1. 1Santa Clara Valley Medical Center, San Jose, California. (Tracking ID # 9334)

BACKGROUND: Alzheimers Dementia is a growing terminal disease that affects not only the patients but also their loved ones and caregivers. Caregiver burden is common and can manifest as mental and/or physical illness as well as social and financial problems. Current outpatient models of care poorly address dementia-related issues. Outpatient group visits for a variety of chronic diseases (such as diabetes) have been studied with variable effects on costs and utilization of health care resources but with positive patient and physician satisfaction. We applied a similar model to a group of Alzheimers Dementia patients and their caregivers. Our hypotheses were that patients behavioral problems and caregiver burden would be more adequately managed and improved with a structured group medical visit facilitated by a physician and medical social worker.

METHODS: Ten patients diagnosed with Alzheimers Dementia and their caregivers from a community geriatric clinic agreed to participate in this observational study. Participants met monthly for 1.5 hours throughout the course of a year. Group medical visits began with an educational talk of interest to the group followed by a series of interval histories focused on one patient-caregiver dyad at a time facilitated by the physician and medical social worker. Caregivers filled out the Zarit Caregiver Burden Interview and Neuropsychiatric Inventory Questionnaire before and after the year-long intervention to assess caregiver stress and the severity of patients behavioral problems, respectively. Paired t-tests were employed.

RESULTS: Five patient-caregiver dyads had complete data sets. There was a trend toward decrease in caregiver burden and stress as well as in severity of patients behavioral problems at the conclusion of the outpatient group meetings although the results were not statistically significant ($p=0.43$ and $p=0.09$, respectively). 4 of the 5 dyads experienced improvement in caregiver stress and patients neuropsychiatric score. If the remaining outlier dyad was excluded, scores became statistically significant ($p=0.05$ and $p=0.02$, respectively). Even though that particular dyad experienced worsening of behavior and caregiver stress, the caregiver expressed an appreciation for the support from the group and staff. Caregivers also felt more knowledgeable about Alzheimers Dementia and about resources in the community. CONCLUSION: Outpatient group medical visits focusing on Alzheimers Dementia education and care may be beneficial for reducing both patient behavioral problems and caregiver stress. Future directions include focusing on specific ethnic groups and assessing for differences in health care usage and medical costs (financial feasibility).

SCORING HOSPITALIST ETIQUETTE Sean Tackett 1; Darlene Tad-y 2; Scott Wright1. 1Johns Hopkins Bayview Medical Center, Baltimore, Maryland; 2University of Colorado at Denver, Denver, Colorado. (Tracking ID # 9395)

BACKGROUND: As physicians are forced to spend more time in indirect patient care activities, particularly on documentation, it has become difficult to establish meaningful physician-patient relationships. Dr. Michael Kahn proposed a checklist of six etiquette-based behaviors as a strategy to improve physician rapport with patients. We hypothesized that the creation of an etiquette-based medicine (EtBM) score could allow for the grading of physician etiquette.

METHODS: Eight hospitalists were randomly selected at each of three hospitals in the Greater Baltimore area and were shadowed by a single observer during a non-admitting shift between May and June 2009. Hospitalists knew only that the observer was conducting a time-motion analysis. Each time the hospitalist entered a patients room, the observer recorded whether etiquette-based medicine behaviors were performed: (1) knocking or asking to enter the patients room, (2) introducing oneself, (3) shaking the patients hand, (4) sitting down in the

patients room, (5) explaining ones role in the patients care, and (6) asking about the patients feelings regarding the hospitalization or his or her illness. EtBM score for each physician was characterized as percentages derived by dividing the number of times EtBM behaviors were performed by number of opportunities to carry them out. Physician activities were recorded at 30 second intervals and categorized as direct patient care (e.g. time spent with patients or their families), indirect patient care (e.g. documentation, coordinating care, writing orders), other activities (e.g. walking, administrative meetings, scholarly work), and personal activities (e.g. meals, restroom breaks, personal calls). Linear regressions were used to assess whether EtBM scores were associated with physician characteristics.
RESULTS: The 24 observed hospitalists collectively saw 226 unique patients and had 389 patient encounters. The average shift length was9.9 hours (SD 1.9), and the average length of each patient encounter was 12 minutes (SD 9). Overall, 18% of hospitalists time was spent in direct patient care, 60% in indirect patient care, 13% in other activities, and 9% in personal activities. EtBM scores for the providers ranged from a low of 3% to a high of 44% (mean 19%). Physician age, gender, and experience were not associated with EtBM scores. Physicians in the top quartile for EtBM score spent more time with each of their patients than those in the bottom quartile (14 vs 12 minutes) and spent a greater proportion of their day in direct patient care (21% vs 16%); both $p<0.05$. CONCLUSION: Higher EtBM scores were more common among physicians spending more time with patients and may represent a marker of patient-centered care. However, EtBM behaviors were infrequently practiced by every hospitalist in the sample thus indicating significant room for improvement.
HYPERGLYCEMIA AND SHORT-TERM OUTCOMES IN PATIENTS WITH ACUTE PULMONARY EMBOLISM
Mean Pascual Marie 1;
Labarere Jose 2; Scherz Nathalie 3; Aujesky Drahomir4. 1University Hospital of Bern, Lausanne, N/A ; 2University Hospital Grenoble, Grenoble, N/A ; 3University Hospital Bern, Bern, N/A ; 4University Hospital of Bern, Bern, N/A . (Tracking ID # 9435)
BACKGROUND: Hyperglycemia is associated with poor outcomes in acute cardiorespiratory diseases, such as myocardial infarction, heart failure, and pneumonia. The prognostic value of serum glucose at admission in patients with acute pulmonary embolism (PE) is unknown. We sought to examine the association between admission glucose levels
and mortality and hospital readmission rates for patients hospitalized with PE.
METHODS: We studied patient discharges with a primary diagnosis of PE from 185 acute care hospitals in Pennsylvania (1/2000-11/2002). Levels of admission glucose were analyzed as a categorical (smaller than or equal to 110, >110 to 140, >140 to 170, >170 to 240, >240 mg/dL) variable. The study outcomes were 30-day all-cause mortality and hospital readmission. We used random-intercept logistic regression to assess the independent association between admission glucose levels and mortality and hospital readmission, adjusting for patient (age, gender, race, insurance, severity of illness using the Pulmonary Embolism Severity Index, use of thrombolytic therapy, troponin, hemoglobin, creatinine, and sodium) and hospital factors (region, size, teaching status).
RESULTS: Among 13,621 patient discharges with PE, hyperglycemia (glucose >110 mg/dL) was present on admission in 8666 patients(63.6%). The majority (80.6%) of hyperglycemic patients did not have recognized diabetes mellitus. Patients with a glucose level smaller than or equal to 110, >110 to 140, >140 to 170, >170 to 240, >240 mg/dL had a cumulative 30-day mortality of 5.6%, 8.4%, 12.0%, 15.6%, and 18.3%, respectively (P smaller than 0.001). Compared to patients with a glucose level smaller than or equal to 110 mg/dL, the adjusted odds of dying were significantly greater for patients with a glucose >110 to 140 mg/dL (OR 1.20, 95% CI: 1.01-1.44), >140 to 170 mg/dL (OR 1.42, 95% CI:1.16-1.76), >170 to 240 mg/dL (OR 1.53, 95% CI: 1.24-1.88) and >240 mg/dL (OR 1.65, 95% CI: 1.32-2.06), with no difference in the odds of hospital readmission.
CONCLUSION: In this large, statewide sample of unselected patients with acute PE, hyperglycemia was common in patients presenting with PE and was an independent predictor of short-term mortality. Given that

hyperglycemia is a potentially harmful and correctable abnormality, whether glucose lowering with insulin has a positive clinical impact in patients with PE needs to be further examined.

COLORECTAL CANCER SCREENING: DIFFERENCES IN RURAL AND INNER CITY, LOW INCOME PATIENTS KNOWLEDGE, BELIEFS, PHYSICIAN RECOMMENDATION AND BEHAVIOR Daci J Platt 1; Connie Lea Arnold 2; Pat Bass 2; Alfred Rademaker 3; Dachao Liu 4; Michael Wolf 4; Terry C Davis2. 1LSU Health Sciences Center Shreveport, Shreveport, Louisiana ; 2Louisiana State University Health Sciences Center Shreveport, Shreveport, Louisiana ; 3Feinberg School of Medicine - Northwestern UniversityNorthwestern University, Chicago, Illinois . (Tracking ID # 9451)

BACKGROUND: Substantial evidence shows that routine screening can prevent colorectal cancer (CRC) or detect it at an early stage and potentially reduce mortality. Less than half of Americans receive CRC screening, with lowest rates among racial/ethnic minorities, low-income individuals, those with fewer years of education, and those living in rural areas. The purpose of this report is to determine differences in rural and inner city patients CRC screening knowledge, beliefs, self-efficacy, physician recommendation and previous fecal occult blood test (FOBT) completion in Federally Qualified Health Centers (FQHCs). METHODS: Eligible patients in six North Louisiana FQHCs (men and women aged 50 and over who had never been screened for CRC or were not up to date) were given a structured interview and a literacy test. RESULTS: Of the 812 patients enrolled (577 rural, 235 inner city) 79% were female, 68% African American (AA), 32% white, 33% less than a high school diploma, and 50% read on less than a 9th grade level. Patients ranged in age from 5074. Inner-city patients were more likely than rural patients to have low literacy (59% vs. 47%, p=.001) and be AA (90% vs. 59%, p<.0001). Of these, rural patients were more likely than inner-city patients to have heard of a colonoscopy (92% vs.76%, p<.0001). Yet rural patients were more likely to strongly agree they would return an FOBT kit (23% vs. 6%, p<.0001). Results remained significant after adjusting for age, race, and literacy.

CONCLUSION: Patients in rural FQHCs have more positive beliefs about the benefits of screening and greater self-efficacy about completing FOBTs than patients in inner city FQHCs, but are less likely to have been given information on FOBTs or received a physician recommendation or an FOBT kit. Greater access to CRC screening information, physician recommendations, and cost effective screening methods are needed in FQHCs, particularly those in rural areas.

SOCIAL, VOCATIONAL, AND EDUCATIONAL OUTCOMES OF OBESITY IN ADULTHOOD Arlene E. Chung 1; Gary R. Maslow 2; Asheley Cockrell Skinner 3; Carolyn T. Halpern 4; Eliana M. Perrin3. 1University of North Carolina at Chapel Hill School of Medicine, Department of Medicine, Division of General Internal Medicine &Clinical Epidemiology, Chapel Hill, North Carolina; 2University of North Carolina at Chapel Hill, Chapel Hill, North Carolina; 3University of North Carolina at Chapel Hill School of Medicine Department of Pediatrics, Chapel Hill, North Carolina; 4University of North Carolina at Chapel Hill Department of Nutrition, Chapel Hill, North Carolina. (Tracking ID # 9549)

BACKGROUND: Adolescents who remain or become obese as they transition to adulthood (20-30 s) may be at risk for lower social, vocational, and educational outcomes. Minimal prior work has assessed a variety of such outcomes. We examined how changes in weight status from adolescence to early adulthood affect social, vocational, and educational outcomes.

METHODS: We examined data from the National Longitudinal Study of Adolescent Health Wave II (1996; 1221 years old) and Wave IV (2008; 2432 years old). Obesity was defined as age-for-sex BMI 95% or greater for those less than 20 years old and BMI 30 kg/m2 or greater for those 20 years old and up. Underweight participants were excluded from the analytic sample (BMI percentile <5%; BMI <18.5 kg/m2). We compared outcomes based on BMI trajectories: healthy weight adolescents (5-85th
percentile) who remained healthy weight (BMI 18.5-25 kg/m2) in early adulthood (healthy-healthy), healthy weight adolescents who became obese in early adulthood (healthy-obese), and obese adolescents who

remained obese (obese-obese). The following outcomes were reported at Wave IV: graduation from high school or college, ever being married, being a parent, living with a parent, having a job, receiving public assistance, and annual income. The final analytic sample (N=6,984)
was weighted to be nationally representative, and logistic regression was used to compare obesity trajectories for outcomes controlling for age, sex, parental education, and race.
RESULTS: Compared to those who were healthy weight during adolescence and remained healthy weight in early adulthood (n=3,682), those who were obese and remained obese (n=1537) had significantly lower odds (see Figure 1) of graduating college and had lower incomes and had higher odds of still living with a parent and being on public assistance. Compared to those who were healthy weight and remained healthy weight (healthy-healthy), those who were healthy weight as adolescents but became obese as adults or healthy-obese (n=1,765) had lower odds of graduating college and greater odds of being parents and being married. There were no statistically significant differences among groups in terms of employment or high school graduation. When separated by sex, differences among groups for income and being on public assistance persisted only for female participants.
CONCLUSION: Persistence of obesity into adulthood, especially for females, is related to lower educational attainment and lower income. Those who become obese in adulthood are also vulnerable. In addition to the detrimental health effects of obesity, the notable negative social, educational, and financial effects of obesity could be impacted by the prevention and reversal of obesity in adolescence and early young adulthood (1221 years old). As this age group has traditionally been difficult to reach, innovative interventions to target and motivate this age group are needed.
HOW MANY LIFE YEARS LOSS FOR MAJOR CANCERS COULD BE SAVED IN THE UNITED STATES IF WE SUCCESSFULLY PREVENT EACH INCIDENT CASE? Pang-Hsiang Liu 1; Nancy Keating2. 1Harvard Medical School, Boston, Massachusetts; 2Harvard Medical School, Newton, Massachusetts. (Tracking ID # 9556)
BACKGROUND: The standard method of computing the person-years of life lost (PYLL) provides a retrospective assessment, counting years of life lost for patients who have died rather than estimating years of life lost for incident cases. Expected years of life lost (EYLL) since diagnosis of cancer would provide another valuable measure of the burden of cancer that can be applied prospectively. The purpose of this study was to estimate the EYLL for patients with one of six types of prevalent and potentially preventable cancer in the United States and to assess the validity of the extrapolation method used among subsets of the cancer cohorts.
METHODS: Patients diagnosed with cancers of the lung, colon and rectum, liver, female breast, cervix, or prostate during 19922005 were identified from the Surveillance, Epidemiology, and End Results registries. Mortality was assessed through 2006. The lifetime survival functions for the cancer cohorts and age- and sex-matched reference populations were generated using a novel semiparametric extrapolation method with annual life tables. The average EYLL for cancer patients was calculated by subtracting the estimated life expectancy of the cancer cohort from that of the reference population. The validation of

the extrapolation of long-term survival was performed using the subcohorts of cancer patients diagnosed during 19921998. We assumed they were only followed till 1998 and extrapolated their survival to an additional 8 years using the semiparametric method. Then we computed extrapolated estimates with the observed gold standard values of the real mean survival within the 15-year follow-up, 19922006.
RESULTS: The estimated life expectancy of a cancer patient since initial diagnosis varied by cancer site from 1.93 years to 20.66 years. Liver cancer and lung cancer had a large average EYLL, 16.7 years and13.8 years respectively, which imply the corresponding life years saved if an incident case could had been successfully

prevented. With multiplication by the annual incidence counts for each cancer in 2010, lung cancer would cause the greatest subtotal of EYLL (3,066,301 years) followed by female breast cancer (1,295,664 years) and colorectal cancer (927,009 years). Validity tests indicated the relative biases of the extrapolated estimates were <3.5%.
CONCLUSION: The potential life years saved by successful prevention, in terms of EYLL since diagnosis, would be substantial for lung cancer, breast cancer, or colorectal cancer. Identifying and improving strategies for prevention of cancer remains a priority to minimize years of life lost due to cancer in the United States. Compared with the average PYLL for a particular cancer, defined by dividing PYLL by the actual number of deaths and reported by the National Cancer Institute, the average EYLL is not a measure of burden of disease for only individuals who died from that cancer but one for populations of incident cancer. Thus the measurement of average EYLL can provide an estimate of how much life is likely to be decreased by cancer on average, allowing for clearer communication with the lay public, clinicians, and policy-makers about cancer risk and life expectancy. It can also allow estimates of the health utility gained or medical cost saved if each incident case of cancer could be prevented successfully. Moreover, the extrapolation method was valid and acceptable, given that the relative biases for the estimates on the cancer subcohorts in the validation process were all less than 3.5%.
END-OF-MONTH HYPOGLYCEMIA ADMISSIONS ARE INCREASED AMONG LOW-INCOME PATIENTS
Hilary Seligman 1; Ann Bolger 1; Nancy Jianhua Jin 1; Kirsten Bibbins-Domingo1. 1University of California San Francisco, San Francisco, California. (Tracking ID # 9590)
BACKGROUND: Almost one in seven households in the United States is food insecure (at risk of going hungry because of the inability to afford food). Because assistance benefits and paychecks are often distributed on the first of the month, food insecure households often exhaust food budgets before the end of the month. Small studies have suggested that
food insecurity is associated with hypoglycemia among patients with diabetes. We hypothesized that the exhaustion of food budgets in low-income households would result in increased hospital admissions for hypoglycemia at the end of the month.
METHODS: We used administrative data on adult discharges from accredited California hospitals between the years 2000 and 2008, available from the California Office of Statewide Health Planning and Development (OSHPD). Data available included diagnosis codes, hospital admission dates, and patient demographics, including home zip code. We examined the admission date of all hospitalizations with a primary discharge diagnosis of hypoglycemia (ICD-9 251.*), and categorized them into quartiles corresponding to the first, second, third, and fourth weeks of the month. We recorded the number of hypoglycemia admissions, and the ratio of hypoglycemia admissions to total hospital admissions. We compared counts and ratios across the first, second, third, and fourth weeks of the month using logistic regression models. We looked for an interaction between week of hypoglycemia admission and patient income estimated using zip-code level data from the US Census Bureau, dichotomized at $30,000. We also looked for week-to-week variation in appendicitis (ICD-9 540.* or 541.*), which we did not expect to be influenced by exhaustion of household food budgets.
RESULTS: A total of 2,558,802 adult hospital admissions occurred in California from 20002008, of which 5461 had a primary diagnosis of hypoglycemia. Although there was no significant week-to-week variation in total hypoglycemia admissions (p=0.5), the association differed by income level (p for interaction=0.02). Among the 4915 admissions for high-income patients, there was no week-to-week variation in admissions. Among the 544 admissions for low-income patients, the average count of hypoglycemia admissions during the first, second, third, and fourth weeks of the month was 109, 114, 141, and 136 episodes (p=0.008), representing a 20% increase in hypoglycemia admissions in the last two weeks of the month. Similarly, the ratio of admissions for hypoglycemia increased significantly in the last two weeks of the month among the low-income patients (p=0.008, see Figure), with the last day of the month showing the highest number of hypoglycemia admissions

at 27 (range of all days 927, mean 18). We observed no week-to-week variation in hospital admissions for appendicitis among high or low income patients.
CONCLUSION: In low-income households, there is a significant increase in hospital admissions for hypoglycemia at the end of the month. Although these data do not allow us to directly link admissions to any single underlying cause, they suggest that hypoglycemia is a critically important safety issue among patients without adequate food access, particularly since the burden of hypoglycemia is likely much larger than reflected in the number of hypoglycemia hospital admissions.

SERUM 2-METHOXYESTRADIOL, AN ESTROGEN METABOLITE, IS POSITIVELY ASSOCIATED WITH SERUM HDL IN A POPULATION-BASED SAMPLE Christopher M. Masi 1; Louise C. Hawkley 1; John T. Cacioppo1. 1University of Chicago, Chicago, Illinois. (Tracking ID # 9601)
BACKGROUND: Serum high-density lipoprotein (HDL) is inversely associated with coronary artery disease, ischemic stroke, and atherosclerosis in men and women. HDL provides atheroprotection by promoting cholesterol efflux from peripheral tissues, transporting cholesterol to the liver for excretion as free cholesterol or bile acids, serving as an anti-oxidant and suppressing inflammation. Serum HDL levels are higher and cardiovascular disease is less prevalent among premenopausal women compared to similarly-aged men. Among postmenopausal women, oral supplementation with conjugated equine estrogen increases serum HDL levels. Studies show that the atheroprotective effects of 17beta-estradiol (E2) are fully retained in estrogen receptor (ER) beta knockout mice and are partially retained in ER alpha knockout mice. This suggests that E2 atheroprotection may operate through receptors yet to be identified or that other factors, such as E2 metabolites, partially mediate E2 atheroprotective effects. A recent study demonstrated that subcutaneous administration of an E2 metabolite, 2-methoxyestradiol (2-MeOE2), to apolipoprotein E-deficient mice led to reductions in both total serum cholesterol and aortic atherosclerotic plaque size compared to control mice. 2-MeOE2 has no affinity for classical estrogen receptors but this metabolite inhibits HMG-CoA reductase in vitro. In vivo, HMG-CoA reductase inhibitors reduce low-density lipoprotein (LDL) and raise HDL. Given these effects, we hypothesized that serum 2-MeOE2 would be positively association with serum HDL. Such an association could shed light on the ER-independent atheroprotective effects of E2.
METHODS: Data for this study were gathered in the fifth year of the Chicago Health, Aging, and Social Relations Study (CHASRS), which is a population-based longitudinal study designed to examine the relationships between psychosocial characteristics and health outcomes among middle-aged and older adults. Participants completed surveys regarding their demographic, dietary, and exercise characteristics, as well as their medication usage. Body mass index (BMI) was calculated as weight in kilograms divided by height in meters squared. The following medications were classified as antihyperlipidemic agents: HMG-CoA reductase inhibitors (statins), niacin, bile acid sequestrants, and cholesterol absorption inhibitors. Serum was analyzed for E2 and 14 estrogen metabolites (EM) using mass spectrometry. EM values exhibited a positively skewed distribution and were therefore subjected to natural log (ln) transformation. Fasting HDL, total cholesterol, and triglycerides were measured using the Cholestech LDX kit (Cholestech Corporation, USA), a system that meets CDC reference standards for accuracy and reproducibility. LDL was calculated using the Friedewald equation. In year 5, we had serum EM data from 51 men and 51 women, all of whom were postmenopausal. Four women were excluded because they were taking hormone replacement therapy. Preliminary analysis revealed no correlation between 2-MeOE2 and serum HDL in men so the current analysis includes only women (N=40) who had no missing demographic, medication, EM, or cholesterol data. Ordinary linear regression analysis was used to evaluate the relationship between serum HDL and predictor variables, including age, race/ethnicity, BMI, use of antihyperlipidemic agents, and serum 2-MeOE2. A one-way t-test of significance was used given our hypothesis of a positive association between 2-MeOE2 and HDL. RESULTS: The mean age for both men and women was 57 years. Correlational analysis revealed a positive relationship between serum 2-MeOE2 and

serum HDL which approached significance among women
(r=0.307; p=0.051) but not among men (r=0.1, p >0.5). None of the other estrogen metabolites was correlated with HDL. Multivariate regression analysis of data from 40 women showed that 2-MeOE2 retained a positive association (p see attached table.
CONCLUSION: Consistent with our hypothesis, we found a positive association between serum 2-MeOE2 and serum HDL. This was true among postmenopausal women but not among similarly-aged men. Oral estrogen supplementation leads to increased HDL in postmenopausal women but the mechanism of E2 non-ER dependent atheroprotection is unknown. Our results are consistent with 2-MeOE2 inhibition of HMGCoA reductase and increased HDL production. Higher levels of serum HDL may explain the ER-independent atheroprotective effects of E2. However, our results are also consistent with the opposite effect (i.e., increased 2-MeOE2 production due to HDL). Prospective studies are therefore needed to determine the causal direction of this association. If 2-MeOE2 is found to increase serum HDL levels in vivo, further investigation of E2 metabolism (especially 2-MeOE2 production) should be pursued. A better understanding of this process could lead to new therapies for cardiovascular disease, especially among postmenopausal women.
THE ASSOCIATION BETWEEN MINOR AND MAJOR ECG CHANGES AND INCIDENCE OF CORONARY HEART DISEASE EVENTS Reto Auer 1; Douglas C. Bauer 2; Pedro Marques-Vidal 1; Javed Butler 3; Lauren Kim 4; Jacques Cornuz 1; Suzanne Satterfield 5; Anne Newman 6; Nicolas Rodondi1. 1University of Lausanne, Lausanne, N/A ; 2University of California San Francisco, San Francisco, California ; 3Emory University, Atlanta, Georgia ; 4National Institute of Aging, National Institutes of Health, Bethesda, Maryland ; 5University of Tennessee Health Science Center, Memphis, Tennessee ; 6University of Pittsburgh, Pittsburgh, Pennsylvania . (Tracking ID # 9689)
BACKGROUND: Electrocardiographic (ECG) abnormalities are common in older adults, but data on their prognostic importance to predict future coronary heart disease (CHD) are conflicting. Our goal was to determine whether baseline ECG abnormalities or development of new and persistent ECG abnormalities during follow-up are associated with increased incident CHD events in older adults, independently of traditional cardiovascular risk factors (CVRFs).
METHODS: We studied 2191 elderly men and women (age range 68 80 years, 59% Caucasian, 41% Black) from the Health, Aging, and Body Composition Study without known cardiovascular disease at baseline. During 8 years of follow-up, self-reported CHD events, defined as hospitalization for acute myocardial infarction, coronary death, angina, angioplasty of coronary arteries and coronary artery surgery, were adjudicated by review of medical records. Baseline study ECG abnormalities were classified according to the Minnesota Code as minor (minor ST-T changes) and major (major ST-T changes, Q-QS wave abnormalities, left ventricular hypertrophy, complete bundle branch block or intraventricular block, atrial fibrillation or atrial flutter). After 4 years of follow-up, 1670 participants had a second study ECG to determine the presence of new or persistent ECG abnormalities. We used Cox models to assess the value of adding ECG abnormalities to traditional risk factors for the prediction of future CHD events. Primary analyses were adjusted for traditional CVRF included in the current Framingham Risk Score (age, gender, total and high density lipoprotein cholesterol, systolic blood pressure, smoking status), as well as diabetes. We categorized 7.5-year estimates for incident CHD as low risk (0% to 7.5%), intermediate risk (7.5% to 15%), and high risk (15% or

more) to calculate net reclassification in the intermediate risk categories using Harrels C index.
RESULTS: At baseline, 276 participants had minor and 506 had major ECG abnormalities. During 8 years of follow-up, 351 participants had CHD events. Minor ECG abnormalities at baseline were associated with an increased risk of CHD (hazard ratios (HR) and 95% confidence interval [CI] 1.45 [95% CI: 1.14 - 1.85] after

adjustment for CVRFs). CHD risk was also increased among those with major ECG abnormalities at baseline (HR=1.51, 95% CI: 1.20 - 1.90) and those with any ECG abnormality defined as either minor and/or major abnormalities (HR=1.64, CI: 1.32 - 2.03). The presence of any ECG abnormality at baseline accurately reclassified 7.1% overall and 13.6% of intermediate risk participants (both P 0.005). Of the 1670 adults with a second ECG after 4 years, 208 had a new abnormality and 416 had a persistent abnormality. After adjustment for CVRFs, both new and/or persistent ECG abnormalities at 4 years were associated with an increased risk of subsequent CHD events (HR=1.67, CI: 1.31 - 2.96 and HR=1.52, CI:1.07 - 2.16, respectively).
CONCLUSION: Minor and major ECG abnormalities in elderly adults are associated with an increased risk of CHD events and provide additional risk stratification information beyond traditional CVRFs. These data suggest a potential value of including ECG findings in the overall assessment of cardiovascular risk in elderly populations.

TRAINING MEDICAL STUDENTS TO CONDUCT MOTIVATIONAL INTERVIEWING: A RANDOMIZED CONTROLLED TRIAL. Jean-Bernard Daeppen 1; Cristiana Fortini 1; Nicolas Bertholet 1; Raphael Bonvin 1; Alexandre Berney 1; Pierre-Andr Michaud 1; Carine 1; Jacques GaumeLayat2. 1Lausanne University Hospital, Lausanne, N/A;
2Lausanne University Hospital Lausanne University Hospital, Lausanne, Lausanne, N/A, N/A. (Tracking ID # 9691)

BACKGROUND: Scientific evidence for the efficacy of Motivational Interviewing (MI) can assist government agencies in recommending its use in medical settings. Research indicates that barriers exist to MI implementation among physicians, thus a strategic time to begin MI training might be during medical school. Several studies have suggested that training medical students improves their MI skills, but no randomized controlled study has addressed the effectiveness when these skills are applied. The aim of our study was to examine the effectiveness of MI training among medical students when they begin counseling patients to change certain health behaviors, such as overuse of tobacco and alcohol, lack of exercise, and unhealthy diets. METHODS: All students (n=131) in year 5 of a 6-year curriculum at Lausanne University Medical School Switzerland were randomized into an experimental (n=66) or a control group (n=65). An 8-hour training workshop was completed by 56 (84.8%) students in the experimental group. The objectives were to adopt the spirit of MI, to use open questions and complex reflections, to recognize and reflect resistance and to elicit and reinforce change talk. One week after the training, students in both the experimental (trained) and the control (untrained) group were invited to meet for 15 minutes with two standardized patients. One was a 60-year-old male with a history of severe nicotine dependence, hospitalized following a myocardial infarction, and the other was a 50-year-old diabetic female with an unhealthy diet, lack of exercise, and problems with medication compliance. Forty-one students in the experimental group and 48 in the control group (or 67.9% of the initial sample) completed these patient encounters which were tape-recorded; MI skills were coded by four blinded research assistants using
the Motivational Interviewing Treatment Integrity 3.0 (MITI). Twenty percent of these were double-coded and had intra-class correlation coefficients between 0.49 and 0.87. Mean MITI summary scores in the experimental group were compared to those in the control group. RESULTS: Superior MI performance was shown for trained versus control students, as demonstrated by higher summary scores for MI Spirit [4.0 (0.6) vs 3.3 (0.6), p<.001], % MI-adherent [80.3 (20.9) vs 47.3(23.3), p<.001], % Open questions [34.5 (11.8) vs 21.1 (7.7), p<.001], % Complex reflections [25.5 (9.9) vs 21.0 (11.6), p=.04], and ratio Reflections/Questions [0.8 (0.4) vs 0.6 (0.3), p<.001], respectively. CONCLUSION: An 8-hour training workshop for medical students with minimal clinical experience was associated with improved MI performance, as evidenced by MI spirit and behavior counts. This lends support for the implementation of MI training in medical schools.

EFFECTIVENESS OF A BRIEF SCREENING TOOL TO IDENTIFY MEDICAL STUDENTS IN SEVERE DISTRESS Lotte Dyrbye 1; Alan Schwartz 2; Steven Downing 3; Jeff Sloan 1; Tait Shanafelt1. 1Mayo Clinic,

Rochester, Minnesota ; 2Department of Medical Education, University of Illinois-Chicago College of Medicine, Chicago, Illinois ;
3Department of Medical Education, University of Illinois-Chicago College of Medicine, Chicago, Illinois . (Tracking ID # 9852)
BACKGROUND: Psychological distress is common among medical students and manifests in a variety of ways (e.g. burnout, depression, low QOL, stress, fatigue, etc.). As this distress can lead to potential dreadful personal and professional consequences and as students are reluctance to seek help there is a need for a practical screening instrument that evaluates multiple dimensions of distress simultaneously and identifies students in greatest need of individualized attention. In this abstract, we report the results from two large multicenter studies that provide validity data on such a brief screening instrument.
METHODS: The ability of the Medical Student Well-being Index(MSWBI) to identify medical students with low mental QOL(defined by having a SF-8 mental component score >1/2 standard deviation below the age and gender-matched population norm), recent suicidal ideation, or recent serious thoughts of dropping out was tested using 2 separate samples of medical students, one sample stemming from a 2007 survey completed by 2230 medical students attending 7 US medical schools and a confirmatory sample of 2682 students surveyed in 2009. RESULTS: Students with low mental QOL, recent suicidal ideation, or recent serious thoughts of dropping out were more likely to endorse each individual MSWBI item and a greater number of total items than students without such distress (all p less than 0.001). Mean mental QOL scores declined as the number of index items endorsed increased ($p<0.0001$ for both genders). The likelihood ratio(LR) for low mental QOL among students with a MSWBI score less than 4 was 0.47 as compared to a LR of 4.79 for those with a score 4 or greater. At a MSWBI threshold score of 4 or greater the sensitivity and specificity of the MSWBI for identifying students with low mental QOL or recent suicidal ideation/serious thoughts of dropping out were both 90% or higher. On multivariable logistic regression all MSWBI items were independently associated with at least one outcome. In the confirmatory sample, the MSWBI again stratified risk for all 3 outcomes with less than 10% differences in sensitivity and specificity at all score levels compared to 2007CONCLUSION: Among two large cohorts of medical students the MSWBI can identify students at risk for clinically relevant outcomes (low mental QOL, suicidal ideation, or serious thoughts of dropping out

of medical school) that warrant recognition and individualized attention. The MSWBI is a useful tool to help medical schools identify students with severe distress which may help schools allocate resources to students in greatest need of assistance.
SELF-AWARENESS OF CULTURAL COMPETENCY IN INTERNAL MEDICINE RESIDENTS: RESULTS OF A TEACHING STANDARDIZED PATIENT ENCOUNTER Patricia Thomas 1; Jorie Colbert2. 1Johns Hopkins University School of Medicine, Glen Arm, Maryland; 2Johns Hopkins University, Baltimore, Maryland. (Tracking ID # 9980)
BACKGROUND: Cultural competency is a necessary skill for all health care professionals. Despite a profusion of cultural competence curricula in health professionals education, there are few validated measures of a trainees cultural competence. We describe here the results of a teaching standardized patient encounter with a behavioral checklist and self-assessment of competence that was used for PGY-1 internal medicine residents.
METHODS: 110 interns from the Johns Hopkins Hospital internal medicine residency program completed the standardized patient (SP) encounter from July 2006 to July 2010. In the 20-minute encounter, the patient was portrayed by an African-American, who expressed both a deep spirituality and a distrust of hospice care, in the context of planning care for the terminal stage of pancreatic cancer. Residents and SPs separately evaluated the encounter using behavioral checklists, derived from literature review of both cultural competence and palliative care communication. Descriptive statistics were used to summarize performance scores. Separate one-way ANOVAs were conducted on test scores for intern year and training month; a 2(student gender) x 2

(SP gender) ANOVA was conducted on test scores to assess gender effects. RESULTS: Cronbachs alpha for the 16-item SP checklist was 0.78. Total scores ranged from 5.50 to 16.00 with a mean of 12.59 (SD=2.28). We found no correlation between performance on the SP checklist and cohort year, month of training, intern gender, or intern-SP gender interaction. Most interns had had prior exposure to cultural competency training, but on average rated themselves 4.44 out of 8 total points for cultural competence skill. When compared with SP scores, 88% of interns underpredicted their cultural competence ability. There was a significant difference in performance between those who over predicted and those who underpredicted their ability. Interns who underpredicted their ability had an average checklist score of 13.17 (SD=1.66) vs. those who overpredicted their ability, average checklist score of 8.35 (SD=1.94), $p<0.001$.

CONCLUSION: The use of an end-of-life scenario enhanced our ability to teach cultural competence in a new context. The checklist proved to be a reliable instrument. In addition to communications skills training, cultural competency education efforts should focus on self-awareness
and situational awareness skills, which appears to be in need of development at least through the PGY1 year.

HEALTH NUMERACY AND LITERACY INFLUENCE MOTIVATIONAL
IMPACT OF DIABETES GENETIC RISK TESTING Jason L. Vassy 1;
Kelsey E. OBrien 1; Jessica Waxler 1; Elyse R. Park 1; Linda M. Delahanty 1; Jose C. Florez 2; James B. Meigs 1; Richard W. Grant1.

(Tracking ID # 10013)

BACKGROUND: Type 2 diabetes (T2D) genetic risk testing has been proposed as a tool to motivate lifestyle modification (LM) for T2D prevention. We hypothesized that health literacy and numeracy influence the interpretation of individual T2D genetic risk. METHODS: We recruited 129 primary care patients at high risk for T2D and assessed their health literacy [Rapid Estimate of Adult Literacy in Medicine (REALM)], genetic literacy [Rapid Estimate of Adult Literacy in Genetics (REAL-G)], and health numeracy (Schwartz, et al. 1997). We assessed participants current motivation to adhere to LM and asked them how these attitudes might change in response to hypothetical higher and lower T2D genetic risk results, using a 5-point Likert scale ranging from much less motivated to much more motivated. We used Fisher exact testing to examine whether anticipated response to genetic risk results varied with literacy and numeracy.

RESULTS: Participants had a mean age of 58 years, 59% were male, 89% were Caucasian, and 81% had greater than high school education. Sixty-seven percent reported very high motivation to prevent T2D. Despite high prevalence of health literacy (93% at high school reading level), many participants had limited numeracy (32%) and genetic literacy (37%). They uniformly reported that higher genetic risk results would increase their motivation for LM (98% reporting increased motivation). In contrast, response to lower genetic risk results varied by participant numeracy and literacy (Figure). Participants with limited numeracy were more likely to predict increased motivation by lower genetic risk results than those with adequate numeracy (65% vs. 44% reporting increased motivation, $p=0.009$). We observed a similar difference in response to lower genetic risk results when contrasting lower vs. higher genetic literacy ($p=0.05$) and lower vs. higher health literacy ($p=0.08$) but not high school or less vs. college education ($p=0.28$).

CONCLUSION: Health numeracy plays a key role in the interpretation of personal genetic risk information. In this fairly educated and motivated patient sample with high health literacy, limited health numeracy was prevalent and influenced how subjects interpreted lower genetic risk results. Numeracy assessment may help tailor the motivational counseling accompanying the delivery of personalized genetic risk information.

VARIATION IN TRIAGE PRACTICES AMONG VETERANS ADMINISTRATION HOSPITALS Lena M Chen 1;

Marta Render 2; Anne E. Sales 2; Edward H. Kennedy 3; Wyndy L. Wiitala 4; Timothy P. Hofer4. 1Ann Arbor Veterans Affairs Medical Center and Division of General Medicine, University of Michigan, Ann Arbor, Michigan ; 2VA Inpatient Evaluation Center, Cincinnati, Ohio ; 3Veterans Affairs Health Services Research and Development Center of Excellence, Ann Arbor, Michigan ; 4Veterans Affairs Health Services Research and Development Center of Excellence; Division of General Medicine, Department of Internal Medicine, University of Michigan, Ann Arbor, Michigan . (Tracking ID # 10014)

BACKGROUND: Variation in the use of critical care for patients at the end of life has been described and identified as a major source of rising health care costs. However, such patients make up only a fraction of all hospital admissions, and hospital triage practices are central to appropriate resource use for all patients. No prior work has examined variation in hospital triage practices within a national healthcare system, and among a broad array of medical patients. In this context, we examined three questions using Veterans Administration (VA) data: 1) on average, does the probability of triage to the intensive care unit (ICU) increase as a patients predicted mortality on admission increases?, 2) among patients with high predicted mortality, how much do hospitals vary in their use of the ICU?, and 3) among patients with low predicted mortality, how much do hospitals vary in their use of the ICU?

METHODS: We used retrospective data from the VA Inpatient Evaluation Center (IPEC), which collects clinical information for inpatient admissions from all VA hospitals, and has developed a validated model for assessing risk of mortality using this data. We constructed a cohort of adult admissions to any VA acute care hospital between July 2009 and June 2010. We included the first admission for all non-surgical patients who were admitted from the Emergency Department or Outpatient Clinic. We excluded VA hospitals with less than 10 ICU admissions. For each admission, we estimated predicted mortality using the IPEC validated inpatient severity score (ISS), based on clinical, laboratory, and demographic variables collected in the 24 hours surrounding admission. We measured the proportion of patients that each hospital admitted directly to the ICU, stratified by categories of ascending mortality risk.

RESULTS: During the study period, 283,976 unique non-surgical patients were admitted to 120 VA hospitals. Of these patients, 31,073(10.9%) were initially admitted to the ICU and 252,903 (89.1%) were admitted elsewhere. Predicted mortality varied by initial triage assignment: direct ICU admissions (ISS=0.082, 30-day mortality=7.7%), and non-ICU ward admissions (ISS=0.042, 30-day mortality=3.5%). Increased predicted mortality was directly associated with an increased likelihood of ICU admission (ascending categories of predicted mortality: 9%, 12%, 14%, 19%, and 28%). At all levels of predicted mortality, hospitals varied significantly in the proportion of patients directly admitted to the ICU. In the lowest category of predicted mortality, 1-49% of patients were admitted to the ICU; in the next highest, 3-50%, then 0-55%, 0-52% and 0-72%.

CONCLUSION: For a broad array of patients at all levels of predicted mortality, hospitals vary widely in their use of critical care, suggesting that there are opportunities for improved efficiency. The causes and consequences of this variation remain to be explored.

PAIN AND DISABILITY IN ELDERS James Andrews 1; Irena Stijacic Cenzer 2; Ed Yelin 3; Kenneth Covinsky2. 1University of California, San Francisco, Burlingame, California ; 2San Francisco VA Medical Center, San Francisco, California ; 3University of California, San Francisco, San Francisco, California . (Tracking ID # 10056)

BACKGROUND: Pain is a risk factor for functional disability in elders. Cross-sectional studies have demonstrated strong relationships between pain and disability. This prospective study aimed to determine if pain predicted the development of disability over time.

METHODS: Our subjects included 12,739 participants over 60 years-old in the 1998 wave of the Health and Retirement Study, a nationally representative sample of community-living adults who are interviewed biannually. Our primary predictor variable was significant pain (report of often being troubled by pain that is moderate or

severe most of the time). Our primary outcome was time to development of disability in activities of daily living (ADL) or death over 10 years. ADL disability was defined as needing help performing any ADL: bathing, dressing, transferring, toileting, eating, or walking across a room. All participants were free of ADL disability in 1998. We used a discrete time survival model to adjust for these potential confounders at baseline: demographic factors (age, race, gender, marital status, education, income), baseline functional status (ADL difficulty, difficulty walking up stairs or more than several blocks), and comorbidity (7 chronic health conditions). RESULTS: At baseline, 2,303 (18.1%) subjects had significant pain. Subjects with pain differed markedly from those without at baseline. Subjects with pain were more likely (all pCONCLUSION: Although many studies have shown strong cross-sectional relationships between pain and disability, after adjusting for baseline functional status, pain does not predict the development of ADL disability.

PHYSICIAN PATIENT-SHARING NETWORKS ARE ASSOCIATED WITH COST AND INTENSITY OF CARE IN US HOSPITALS Michael Lawrence Barnett 1; Nicholas A Christakis 2; Alistair James OMalley 2; Jukka-Pekka Onnela 2; Nancy Lynn Keating 2; Bruce Evan Landon2.

1Harvard Medical School, Brookline, Massachusetts; 2Harvard Medical School, Boston, Massachusetts. (Tracking ID # 10060)

BACKGROUND: Substantial variation exists in the cost and intensity of care received by patients treated by physicians affiliated with different US hospitals. There is currently no consensus on the mechanisms that underlie such marked variation in health care delivery across the US. Using measures from the discipline of network science, we assessed how the organization of patient-sharing networks of physicians affiliated with hospitals might contribute to this variation. We hypothesized that network measures reflecting poorer coordination of care within hospital-affiliated networks would be associated with higher costs and care intensity. METHODS: We performed a cross-sectional analysis of Medicare administrative data from 2006 for patients in 51 hospital referral regions (HRRs), resulting in a sample of 61,461 physicians affiliated with 528 hospitals caring for 2.6 million Medicare patients. We constructed hospital-affiliated physician networks based on shared patients and measured aspects of the structure of these hospital networks including the median number of connections per physician and the relative centrality of primary care or specialist physicians in the hospital network. We then used multivariate linear regression to assess the relationship between network structural measures and total health care spending and care intensity (including both inpatient and ambulatory care) in the last 2 years of life for Medicare patients, controlling for a number of hospital characteristics. RESULTS: The typical physician in an average-sized hospital was connected to 187 doctors for every 100 Medicare patients shared with other doctors. In larger hospitals, the typical physician was connected to 281 other doctors per 100 Medicare patients. An increase of one

standard deviation (SD) in the median number of connections per physician was associated with a 17% increase in total Medicare spending, 17% more hospital days, 36% more ICU days, and 37% more specialist visits (all pCONCLUSION: Hospital-affiliated physician network structure has a significant relationship with care patterns for Medicare patients. Hospitals with more specialist-focused networks and those with doctors who have higher numbers of connections to other physicians have higher costs and more intensive care. These results highlight the importance of physician relationship networks and provide support for the hypothesis that poorer coordination of care is associated with greater spending and care intensity.

MAPPING PHYSICIAN NETWORKS WITH SELF-REPORTED AND ADMINISTRATIVE DATA Michael Lawrence Barnett 1; Bruce Evan Landon 2; Nancy Lynn Keating 2; Alistair James OMalley 2; Nicholas Alexander Christakis2. 1Harvard Medical School, Brookline, Massachusetts;

2Harvard Medical School, Boston, Massachusetts . (Tracking ID # 10061)

BACKGROUND: Relationships between healthcare providers are essential to a functioning health care system and form the basis for the referral and information exchange networks in health care. These networks can be

analyzed using tools from the discipline of network science, yielding potentially valuable insights into the emergence of local health care practice patterns and diffusion of health care practices. However, network data are not readily available and require meticulous collection of information on hundreds or thousands of relationships between providers. Potentially, administrative claims data can be used to infer physician networks by linking physicians if they share patients. We designed and implemented a novel web-based survey to assess if connections between physicians based on shared patients in administrative data correspond with professional relationships between physicians.
METHODS: We performed a web-based survey of physicians affiliated with a large academic and community physicians organization. We used 2006 Medicare data from a 100% sample of patients in the Boston hospital referral region to measure patient sharing between physicians in our sample. Physicians were eligible for the survey if they were members of the physicians organization, filed claims for Medicare patients in 2006, and practiced in an office-based patient care specialty. The survey asked respondents about referral and advice relationships with physician colleagues. Respondents were asked to give names of physicians they referred to in addition to being presented with an individualized roster of physicians names with whom they did and did not share patients based on Medicare data. Relationships measured by this questionnaire were compared with relationships assessed by patient sharing, measured using 2006 Medicare data.
RESULTS: In total, we received responses from 386 of 616 eligible physicians (response rate 63%). The probability of two physicians having a recognized professional relationship increased with the number of Medicare patients shared in the administrative data, to a maximum of 82% of relationships recognized by respondents when sharing 9 patients with other physicians (Figure 1). The area under the curve (AUC) of the ROC curve when considering the number of patients shared physicians as a diagnostic test to predict any relationship between physicians was 0.73 (95% CI: 0.70-0.75). Primary care physicians (PCPs) were more likely to recognize relationships than medical or surgical specialists ($p<.001$).
CONCLUSION: Patient sharing identified using administrative data is an informative diagnostic test for predicting the existence of relationships between physicians. In addition, we find that primary care physicians are more likely to recognize relationships with other providers than specialists, a finding consistent with PCPs role as care coordinators. These findings validate a method that can be used for future research to map and study networks of physicians.
HIV AND THE HOMELESS: THE EFFECTS OF HOUSING STATUS ON HIV DISEASE PROGRESSION AND HEALTHCARE ACCESS Sarah Shelby 1; Cheryl Ho 1; Edward Brooks 1; Dean Winslow 1; Ahmad Kamal 1; Sara Doorley1. 1Santa Clara Valley Medical Center, San Jose, California. (Tracking ID # 10072)
BACKGROUND: The question of how housing status influences HIV control and healthcare access has yielded conflicting results. Several studies have shown that homeless HIV positive patients tend to have more poorly controlled CD4 counts and viral loads while other studies have shown no difference. Prior studies have also demonstrated variability in healthcare access patterns. This study was performed to compare CD4 count, viral load, and health care utilization patterns of the homeless and housed HIV positive patients who attend the Partners in AIDS Care and Education (PACE) Clinic, which is the HIV primary care clinic for Santa Clara County in San Jose, CA.
METHODS: This study was a retrospective, observational study of patients who attended PACE Clinic in 2009. Of the 1200 patients who attend PACE clinic, 33 patients were identified as being homeless and 66 patients were chosen by a random number generator from the remaining stably housed patients at PACE clinic as a control. Data was obtained from the AIDS Regional Information and Evaluation System ARIES database of California as well as county medical records regarding clinic attendance, ED visits, CD4 counts, viral load, and number of lab tests in 2009. SPSS was used to test for significant differences between the homeless and the housed population of HIV positive patients.
RESULTS: Homeless subjects had a lower mean CD4 count than housed subjects (351 vs. 494, $p=0.007$ by the

t-test) as well as a lower rate of undetectable Viral Load (36% vs. 65%, p=0.007 by the chi-square test). Homeless patients had more ED visits by the Wilcoxon Rank Sum Test (p=0.002) and a lower retention rate in the PACE Clinic (33% vs. 59%, p=0.02 by the chi-square test). However the total number of clinic visits per patient was not different between the homeless and housed populations at PACE (p=0.09 by Wilcoxon Rank Sum Test).

CONCLUSION: In our patient population, housing status significantly influenced HIV control (estimated by CD4 count and viral load) and healthcare access. In the homeless patients, CD4 counts were lower and viral loads were less likely to be undetectable. Increased ED visits in the homeless patients, coupled with similar number of clinic visits, may indicate that these patients have a more complicated HIV course for socioeconomic reasons, and that this population may benefit from an increased frequency of clinic visits. Perhaps these patients had more difficulty making their scheduled appointments and would benefit from the walk-in clinic model that has worked for local homeless clinics. Further research is needed to determine what barriers to better HIV control exist for the homeless HIV positive patients of Santa Clara County, and what could be done to overcome these barriers in the future.

TARGETING SCARCE CLINICAL RESOURCES IN REAL-TIME: AN EMR-BASED INTERVENTION TO REDUCE HEART FAILURE READMISSIONS Ruben Amarasingham 1; Parag Patel 2; Kathy Toto 1; Timothy Swanson 1; Lauren Nelson 1; Billy Moore 1; Ying Ma 1; Christopher Clark 1; Kashundra Foreman 1; Kristin Alvarez 1; Anita Rahman 1; Ethan Halm2. 1Parkland Health &Hospital System, Dallas, Texas; 2University of Texas Southwestern Medical Center, Dallas, Texas. (Tracking ID # 10078)

BACKGROUND: 30-day readmission for heart failure (HF) has gained widespread attention as a federal pay-for-performance measure. Current approaches to improve readmission performance recommend intensive clinical and case management interventions for all patients admitted with HF, an organizational posture difficult to sustain for many institutions, particularly safety net hospitals. In this study, we test a novel, multi-disciplinary approach to reduce HF readmissions that tailors the intensity of the intervention to the risk of the patient using a real-time electronic predictive model.

METHODS: We conducted a prospective cohort study to assess the impact of the intervention on rates of readmission for adult inpatients admitted with HF between December 1, 2008 and December 1, 2010 at Parkland Memorial Hospital, an 800-bed safety net hospital in Dallas, TX. During the intervention period (December 1, 2009 to December 1, 2010), a software platform we developed stratified all admitted HF patients on a daily basis according to their risk for 30-day readmission using a previously published electronic predictive model. The electronic platform calculated the risk of readmission using clinical, social, behavioral, and utilization data that it self-extracted from the hospital electronic medical record (EMR) within 24 hours of admission. HF patients in the 2 highest quintiles of risk were immediately assigned to an intensive set of evidence-based interventions designed to reduce readmission including: a) detailed clinical assessments, patient coaching and discharge planning by a HF nurse practitioner, pharmacist, nutritionist, and case manager; b) a follow-up nurse phone call within 48 hours of discharge (D/C); c) outpatient case management for 30 days including home visits; d) a cardiology appointment with a HF specialist within 7 days of D/C; e) and a primary care appointment within 30 days of D/C. HF patients in the lower 3 quintiles of risk received less intensive discharge planning, and no involvement of the HF clinicians, case managers, or home visit nurses. Readmission for any cause and to any hospital within 30 days of discharge was collected for all patients. We calculated both crude and adjusted readmission rates before and after the intervention. Adjusted analyses controlled for: 1) patient clinical and SES factors, and 2) the change in readmission rates among patients hospitalized for 2 concurrent control conditions (acute myocardial

infarction [AMI] and pneumonia [PNA]), allowing for adjustment of secular readmission trends at the institutional level.
RESULTS: There were 779 HF admissions (1435 for AMI or PNA) in the pre-intervention period and 753 HF admissions (1446 for AMI and PNA) in the post-intervention period. The pre- and post-populations were similar across clinical and socio-demographic variables. Although the clinical and case management interventions were restricted to patients in the top 2 quintiles of calculated risk, the overall unadjusted readmission rate for HF declined from 20.2% in the pre-intervention period to 16.0% in the post-intervention period (p=.04). In contrast, the readmission rate for PNA and AMI did not change (12.0% vs. 13.9%, p=0.34). In the final adjusted analysis, the readmission rate for patients with HF was significantly lower in the intervention period (15.7% vs.21.5%; adjusted incidence rate ratio, 0.72 [95% CI, 0.55 to 0.95]; p=.02). A sub-group analysis revealed that the intervention was especially effective among Medicare recipients, with a decline in overall adjusted readmission rates from 24.5% (similar to the mean incidence nationally) to 13.5% (within the top decile nationally; aIRR=0.57, CI,0.55-0.99; p=.05). There was no corresponding change in readmissions among Medicare patients with AMI and PNA (12.0% vs 13.0%; p=.80). CONCLUSION: A novel, electronic strategy that carefully directs scarce clinical resources to highest risk patients significantly reduced 30 day readmission rates among patients with HF at a large, safety net hospital. Real-time electronic predictive models may allow institutions to concentrate resources more effectively, enabling more powerful interventions in an era of constrained resources.
REDUCTION OF CATHETER-ASSOCIATED URINARY TRACT INFECTIONS THROUGH A BUNDLED INTERVENTION IN A COMMUNITY HOSPITAL Karen Ann Clarke 1; Bonnie Norrick 2; Kirk Easley 1; Yi Pan 1; David Tong 1; Alan Wang 1; Pennie Hill 2; Jason Stein1. 1Emory University, Atlanta, Georgia; 2West Georgia Health, LaGrange, Georgia. (Tracking ID # 10083)
BACKGROUND: Urinary tract infections (UTIs) are the most common type of hospital-acquired infection, and 80% are associated with indwelling urinary catheters. The relatively high frequency of catheter-associated UTIs (CAUTIs) leads to clinical and financial concerns for both patients and hospitals. Since Medicare and other payers no longer cover the costs of treating CAUTIs, the development of cost-effective strategies to reduce their incidence has received increased attention.
METHODS: We retrospectively examined the effect of a bundle of four evidence-based interventions, introduced in staggered fashion, upon the incidence of CAUTIs in a 276-bed community hospital. Rates of CAUTI per 1000 catheter days were estimated and compared using exact methods based on the Poisson distribution. The first intervention was the exclusive use of silver alloy catheters in the acute care areas of the hospital, the use of which had been sporadic in the hospital over the previous 3 years. The second intervention was a new securing device to limit movement of the indwelling catheter after insertion. The third intervention consisted of repositioning the catheter tubing if it was found to be touching the floor. A two-month run-in period began when the first intervention was started in January 2009, and ended when the routine use of the second and third interventions was introduced the following month. The fourth intervention, which was implemented in October 2009, was the removal of indwelling urinary catheters on postoperative day 1 or 2, for most surgical patients.
RESULTS: For the 3 month baseline (October 1-December 31, 2008) before the run-in period, the mean rate of CAUTI per 1000 catheter days was 5.2, and that for January 1-February 28, 2009 was 6.5. For the

7 months after full implementation of the first three interventions (March 1 - September 30, 2009), the mean rate of CAUTI per 1000 catheter days was 3.1, which was a nonsignificant reduction compared to January 1-February 28, 2009 (p=0.09). For the seven months after the implementation of the fourth intervention (October 1, 2009 - April 30, 2010), the mean rate of CAUTI per 1000 catheter days decreased
further to 1.5, which was significantly lower than the rate for January 1-February 28, 2009 (p=0.009).

CONCLUSION: A bundle of four evidence-based interventions reduced the incidence of CAUTIs by two-thirds in a community hospital. These relatively simple interventions should be easily sustainable and could be readily transferable to other hospitals.

Table 1:

Incidence Rate of CAUTIs per 1000 catheter days from October 2008 to April 2010

Time interval	Oct-Dec 2008	Jan-Feb 2009	Mar-Sep 2009	Oct 2009-Apr 2010
CAUTI rate (per1000 catheter days)	5.2	6.5	3.1	1.5

UTILITY OF SELF-REPORT AND ELECTROCARDIOGRAM Q-WAVES FOR ESTIMATING MYOCARDIAL INFARCTION PREVALENCE: AN INTERNATIONAL COMPARISON STUDY Daniel Turner-Lloveras 1; Aayla Khan 2; Walter Palmas 3; Dirk DeBacquer 2; Andrew Moran1.
1CUMC, New York, New York; 2CUMC, New York, New York; 3CUMC, New York, New York. (Tracking ID # 10088)

BACKGROUND: Self-report of physician diagnosis and electrocardiogram (ECG)-Q waves are common survey measures of prior myocardial infarction (MI) prevalence but each has limited accuracy. Both represent low-cost methods for assessing ischemic heart disease burden, especially in low resource settings. The objective of this study is to assess relative prevalence of self-reported prior MI and ECG Q-waves (ECG-MI) in populations and population sub-groups with varying MI incidence.

METHODS: Prior MI self-report and ECG-MI (Minnesota ECG codes 1.1 and1.2) were analyzed in men and women age 4574 years in two large population-based samples: pooled Belgian surveys (19781998, N=29,419) and U.S. National Health and Nutrition Examination Surveys (19761994, N=11,107). Self-reported MI and ECG-MI were also compared in men and women aged 4059 years among U.S. and Belgian surveys and in selected eligible studies representing seven other nations (United Kingdom, Russia, Lithuania, Belarus, India, Turkey and Ghana).

RESULTS: Self-reported prior MI prevalence was 1.5-2.6 times higher than ECG-MI in Belgian and U.S. men aged 4574 years and women 5574 years. Self-reported MI was less prevalent than ECG-MI in women lower than ECG-MI in U.S. African American men aged 45 74 years (1.2 compared with1.7 in Whites). In the nine nation comparison, there was no consistent relationship between self-reported MI and ECG-MI (Figure). ECG-MI was generally highest relative to self-report in lower ischemic heart disease incidence nations.

CONCLUSION: Self-reported MI and ECG-MI prevalence may only be reliable in higher ischemic heart disease incidence groups. Limited accuracy of self-report and ECG-MI should lead to a search for better MI prevalence measures. In assessing the burden of ischemic heart disease, current survey prevalence measures cannot substitute for population incidence and mortality surveillance.

MULTI-SESSION SELF-CARE TRAINING IMPROVES KNOWLEDGE, SELF-EFFICACY AND SELF-CARE BEHAVIORS FOR LOW AND HIGH-LITERACY PATIENTS WITH HEART FAILURE George Mark Holmes 1; Darren Andrew DeWalt 2; David Baker 3; Dean Schillinger 4; Victoria Hawk 2; Bernice Ruo 5; Kirsten Bibbins-Domingo 4; Morris Weinberger 2; Aurelia Macabasco-OConnell 6; Kathleen Grady 6; Kimberly Broucksou 2; Brian Erman 2; Michael Pignone2. 1University of North Carolina, Chapel Hill, North Carolina ; 2UNC, Chapel Hill, North Carolina ; 3Northwestern University, Chicago, Illinois ; 4UCSF, San Francisco, California ; 5Northwestern University, Evanston, Illinois ; UCLA, Los Angeles, California . (Tracking ID # 10092)

BACKGROUND: Heart failure (HF) self-care training reduces heart failure-related hospitalizations but the optimal amount of support is not clear. We conducted a multi-site randomized trial comparing a single session only (SS-only) vs. a teach to goal (TTG) multisession educational and self-care support program for improving

key knowledge and skills for effective heart failure self-management.
METHODS: We randomized ambulatory patients with symptomatic HF from 4 academic medical centers to: 1) a single face-to-face one hour educational session with a focused self-care curriculum (SS-only) or 2) TTG: the same single session plus 58 telephone education sessions over the next month and continued calls every 2 to 4 weeks for 12 months that taught to knowledge and behavioral goals. Educational sessions were designed to overcome literacy-related barriers to effective self-care. We stratified randomization by literacy status (adequate or inadequate/marginal). Outcomes were assessed at baseline (pre-randomization) and 1, 6, and 12 months, for measures of three key domains: disease-specific knowledge, self-efficacy, and self-care. Generalized estimating equations (accounting for within-individual correlation across the different collection periods) were used to estimate the difference in changes due to the intervention.
RESULTS: 605 participants were randomized: 302 to the SS-only group and 303 to the TTG group. The mean age was 61 years; 48% were female; 38% African-American and 16% Latino; 26% had less than a high school education; 69% had ejection fraction less than 0.45; 31% were NYHA class III or IV; 37% had low literacy. Response rates were approximately 88%, 90% and 83% in the 1, 6, and 12-month follow-up surveys respectively and did not differ between 2 study arms. Members

of the SS-only group experienced improvements in all three measures between baseline and the 1-month follow up. The TTG group improved all three measures 60% to 136% more than the SS-only group at 1 month (all p-values less than 0.05), and these differences were preserved at 6 and 12 months (Figure). Although those with low literacy had lower scores for all four measures at baseline, the improvements were similar for both low and high literacy groups.
CONCLUSION: A literacy-sensitive, multi-session teach to goal self-care training intervention appeared to improve the knowledge and skills considered necessary for effective self-management of heart failure more than a single educational session, and did so similarly for low and high literacy groups.
DRUG-RELATED RISK FACTORS FOR DEATH AFTER RELEASE FROM PRISON: A NESTED CASE CONTROL STUDY Ingrid A Binswanger 1; Patrick J Blatchford 1; Traci E Yamashita 1; Marc F Stern2. 1University of Colorado Denver, Aurora, Colorado; 2University of Washington, Tumwater, Washington.
(Tracking ID # 10117)
BACKGROUND: International studies have shown former prisoners to be at high risk for death after release from prison, particularly from drug-related causes such as overdose. Despite this, little is known about whether substance use-related factors, identified in prison, are associated with death after release from prison. Thus, the objective of this study was to examine the substance use-related risk factors for all-cause and overdose death after release from prison.
METHODS: We conducted a case control study nested within a retrospective cohort study of inmates released from the Washington Department of Corrections from 19992003. Cases (n=443) were individuals who died after release from prison, based on matching with the National Death Index. Controls (n=443) were selected using risk set sampling (i.e. at risk at the time the case died relative to release), and matched to cases by age and gender. Correctional medical, pharmacy, and substance abuse records were abstracted using a structured data abstraction tool. We compared cases and controls in the following factors, as recorded in prison charts prior to the release: lifetime substance dependence based on DSM-IV criteria, history of injection drug use, narcotic prescriptions received in the 60 days prior to release, and known HIV or AIDS. Data were analyzed using conditional logistic regression. Analyses were adjusted for race/ethnicity and length of incarceration (factors previously shown to be associated with mortality), and having children and marital status (measures of social support). A separate model examined overdose cases (n=103) compared with controls (n=103) with the same

covariates.
RESULTS: Together, cases and controls were predominantly male (88%) and had an average age of 41 years. Substance dependence was recorded in 53%, injection drug use in 41%, narcotic prescriptions in 5%, and HIV/AIDS in 1%. Injection drug use (odds ratio [OR] 1.84, 95% confidence interval [95% CI] 1.34, 2.52) and HIV/AIDS (OR 10.02, 95% CI 1.24, 81.01) were associated with increased odds of all-cause mortality. Substance dependence (OR 0.90, 95% CI 0.67, 1.22) and narcotic prescriptions (OR1.13, 95% CI 0.59, 2.17) were not associated in the adjusted model. Having children was protective (OR 0.70, 95% CI 0.51, 0.95) but marital status was not associated. The only substance use-related factor associated with overdose mortality was injection drug use (OR 7.28, 95% CI 2.84, 18.68). CONCLUSION: Injection drug use history was an independent risk factor for all cause and overdose mortality after release from prison and HIV/AIDS was a risk factor for all-cause mortality. We were surprised that substance dependence was not independently associated with either outcome. Substance dependence, as ascertained by correctional staff, may
be insufficiently sensitive to identify high-risk groups of inmates given its high prevalence in this population. The lack of association of pre-release narcotic prescriptions with mortality may provide some reassurance to correctional physicians who treat pain. Further work to identify risk factors for death which can be easily ascertained in prison and more narrowly define the population at risk is necessary, but, in the meantime, injection drug users may be considered a target group for interventions to reduce mortality after release from prison.

FOOD INSECURITY AND GLYCEMIC CONTROL AMONG PATIENTS WITH DIABETES Hilary Seligman 1; Elizabeth Jacobs 2; Nancy Jianhua Jin 1; Andrea Lopez 1; Alicia Fernandez1. 1University of California San Francisco, San Francisco, California; 2Rush, Chicago, Illinois. (Tracking ID # 10128)

BACKGROUND: Food insecurity refers to the inability to reliably afford safe and nutritious food. Almost 15% of households in the US are food insecure. In addition to reductions in the quantity of food consumed, food insecurity is also associated with a reduction in the quality of food consumed, with a shift in intake toward inexpensive, calorically-dense foods (added fats/sugars, refined carbohydrates) which raise blood glucose. We hypothesized that food insecurity would therefore be associated with poor glycemic control among adults with diabetes. METHODS: We examined the association between food insecurity and glycemic control in a cross-sectional, observational study of 711 English-and Spanish-speaking patients with type 2 diabetes. All patients were receiving ongoing care in safety-net health clinics in San Francisco or Chicago. Participants were enrolled and completed questionnaires between June 2008 and July 2009. We assessed food insecurity using the short form of the Food Security Survey Module. Our main outcome measure was poor glycemic control, which we defined a priori as HbA1c greater than or equal to 8.5%. We compared baseline characteristics using chi-square tests and used generalized regression models to determine whether an association existed between food insecurity and glycemic control. We subsequently determined whether difficulty following a diabetic diet, diabetes-specific self-efficacy, or diabetes distress mediated observed associations. RESULTS: The prevalence of food insecurity in our sample was 46%. Food insecure participants were younger than food secure participants (53 vs 56 years, pCONCLUSION: Food insecurity is a strong predictor of glycemic control and thus may contribute to inequities in diabetes-related complications. Translation of diabetes interventions into low-income settings should specifically address participants limited financial ability to afford diabetes-appropriate foods.

THE USE OF LOWER QUALITY ENDPOINTS AND OF RELATIVE (VERSUS ABSOLUTE) RISK REPORTING IN PUBLISHED RANDOMIZED TRIALS Michael Hochman 1; Danny McCormick2. 1UCLA, Santa Monica, California; 2Cambridge Health Alliance, Cambridge, Massachusetts. (Tracking ID # 10131)

BACKGROUND: Because of their potential to generate erroneous conclusions and distort study findings, concerns have been raised about the use of surrogate endpoints, composite endpoints, multiple primary endpoints, disease-specific mortality as an endpoint, and relative (rather than absolute) risk reporting in clinical

studies. METHODS: We analyzed of all randomized medication trials published in the six highest impact general medicine journals between June 1,

2008 and September 30, 2010 to determine the prevalence of the use of surrogate endpoints, composite endpoints, multiple primary endpoints, disease-specific mortality as an endpoint, and of relative risk reporting. In addition, we examined whether a trials funding source and outcome(i.e. positive vs. negative results) is associated with the use of these endpoints or with relative risk reporting.
RESULTS: We identified 316 medication trials, of which 116 (37%, 95% CI, 31%-42%) used a surrogate primary endpoint, 106 (34%, 95% CI, 28%-39%) used a composite primary endpoint, and 48 (15%, 95% CI, 11%-20%) used multiple primary endpoints. Among 118 trials in which the primary endpoint involved mortality, 32 (27%, 95% CI, 19%-36%) used disease-specific mortality rather than all-cause mortality. Among 157 trials with positive results, 69 (44%, 95% CI, 36%-52%) reported these results in the abstract exclusively in relative terms. Trials using surrogate endpoints and disease-specific mortality as an endpoint were more likely to be commercially funded compared to those not using these endpoints. In addition, trials using surrogate endpoints were more likely to report positive results while those using mortality endpoints were less likely to be positive.
CONCLUSION: Trials published in high impact medical journals frequently use surrogate endpoints, composite endpoints, multiple primary endpoints, and disease-specific mortality as an endpoint, and frequently report results exclusively using relative numbers.
PERSISTENCE WITH ADJUVANT HORMONAL THERAPY IN OLDER BREAST CANCER SURVIVORS Tyler Hedin 1; Changbin Guo 1; Ann Nattinger1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 10132)
BACKGROUND: Breast cancer survivors with hormone receptor positive disease are typically prescribed tamoxifen or an aromatase inhibitor (AI) as adjuvant hormonal therapy for a 5-year course to reduce the likelihood of recurrence. Despite its benefit in breast cancer patients, prior studies on tamoxifen have found sub-optimal rates of adherence to the prescribed 5-year course. Less is known about adherence rates in patients using an AI. This study aims to identify the extent of non-persistence to adjuvant hormonal therapy among older breast cancer survivors as well as examine self-reported reasons for non-persistence.
METHODS: We recruited 3083 Medicare breast cancer patients who underwent initial surgery in 2003 and resided in California, Florida, New York, or Illinois. Four survey waves between 2005 and 2008 assessed receipt of hormonal therapy (HT) as well as demographic, social, and treatment factors. Stage 1 or 2 subjects who initiated HT within 1 year of surgery (n=1402) were included. In accordance with the International Society for Pharmacoeconomics and Outcomes Research Medication Compliance and Persistence Work Group, patients were defined as persistent if HT was utilized for at least 5 years from the initiation of therapy without a gap in treatment of more than 60 days. A multinomial model was constructed to determine which demographic factors were associated with which self-reported reasons for non-persistence. RESULTS: Of the 1402 breast cancer survivors studied, 325 (23%) discontinued their HT within 5 years of their surgery. Reasons for nonpersistence were provided by 280 (86%) of those discontinuing therapy early. The most common reason for non-persistence was side effects (47% of subjects), followed by belief they had finished therapy (17%), physician-directed discontinuation (15%), and cost (8%). Thirteen percent had other reasons for discontinuation and were excluded from the multinomial analysis. Factors associated with reasons for nonpersistence were age (p=0.025), marital status (p=0.015), household income (p=0.045), and supplemental insurance in addition to Medicare (p=0.047). The multivariate model concurrently controlled for each of
these factors, enabling comparisons to those discontinuing due to side effects. Older subjects (>75 years) were more likely to discontinue treatment due to physician direction (p=0.01) or completion of treatment (p=0.04) than due to side effects. Married subjects were less likely to discontinue due to cost (p=0.05) than due to side effects. Higher income subjects were less likely to discontinue due to cost or completion of treatment (p=0.04)

than due to side effects. Subjects with no supplemental insurance were more likely to discontinue due to cost (p=0.06) than due to side effects. Race, marital status, education, stage of disease, co-morbidities, and type of surgery were not significantly associated with specific reasons for non-persistence.
CONCLUSION: This study confirms that a substantial minority of patients are failing to remain on adjuvant HT for the standard duration of 5 years. Most women discontinued due to perceived side effects. Cost was a particular issue for those who were older, unmarried, poorer, and with poorer insurance coverage. Some women believed they had completed treatment prior to 5 total years of therapy. Identifying the predictors and reasons for early discontinuation of treatment is essential to formulating intervention strategies to improve persistence.
PAGE ME IF YOU NEED ME - DYSFLUENCY ON ROUNDS (THE WRONG MESSAGE) Lawrence Loo 1; Nishant Puri 1; Douglas Hegstad 1; Anas Kawayeh 1; Daniel Kim1. 1Loma Linda University School of Medicine, Loma Linda, California. (Tracking ID # 10138)
BACKGROUND: Effective July 1, 2011, the Accreditation Council for Graduate Medical Educations (ACGME) new common program requirements call for enhanced supervision and communication to ensure patient safety while maintaining a humanistic training environment. The Institute of Medicines (IOM) report on Resident Duty Hours stresses that resident supervision is key to achieving these goals. Discrepancies exist between what residents and attending physician perceive as adequate supervision. Part of this discrepancy is attributable to the differences among attending physicians and the mixed messages sent to residents that result in dysfluency on rounds and the establishment of an organizational hidden curriculum. We sought to illuminate these differences among attending physicians and characterize the variety of messages sent to resident physicians in order to assess their impact on resident supervision and communication. METHODS: To document the current practices in a University based categorical Internal Medicine (IM) residency, 79/88 categorical IM residents (90% response rate) and 35/82 (43 %response rate) attending physicians were surveyed about their current attitudes and routine behaviors regarding resident supervision. Using an audience-response system for immediate feedback and discussion, resident and attending physicians were polled separately and asked to respond to three different measures of resident supervision including: (1) six commonly encountered clinical care situations that involved patient safety issues; (2)nine frequently used phrases by attending physicians before leaving the hospital on call days; and (3) six sets of different personality types of attending physicians encountered in the training program. Results comparing and contrasting the differences and similarities were presented at a departmental academic affairs meeting to facilitate discussion and highlight discrepancies as preparatory background in developing a uniform residency policy to meet the ACGMEs call for enhanced supervision. RESULTS: Clear differences in the perception of resident supervision were found between resident physicians and attending physicians in commonly encountered clinical care situations that involved patient safety. For example, notification of the attending physician of an unexpected pneumothorax requiring chest tube placement was desired by 85% of the attendings but only 31% of residents said they would call

their attending (see Figure 1). Common phrases such as page me if you need me resulted in 50% of residents rarely or never calling their attending physicians, 41% sometimes calling and only 9% of residents responding to mostly or always calling their attending physician. Any reference made by the attending physician to having other activities to do while on call (e.g. dinner engagement) or when they slept, only lessened the frequency of calls by the residents. While personality types of the attending physicians (e.g. friendly versus strict and intimidating) affected communication frequency, the phrase I want to be called on all patients you admit or have a change in status significantly changed the behavior of the resident physician to call their attending. (see Figure 2) CONCLUSION: Our results confirm prior studies that attending physicians generally would like more

communication and closer supervision than routinely perceived by resident physicians. Significant discrepancies exist among attending physicians regarding the need for communication and frequency of resident supervision. The accompanying mixed messages create an organizational hidden curriculum that creates dysfluency on call days and confusion among residents. These differences must be brought to light, acknowledged, and vetted before developing a uniform departmental approach to meet the ACGMEs enhanced supervision policy to ensure patient safety while maintaining quality resident education. Our simple and easy to use tool highlights these differences and serves as a basis for this initial and fundamental discussion to occur. Clear and unambiguous phrases such as I want to be called on every patient admission should be included in departmental policies designed to ensure patient safety and consistent resident supervision.

A MULTISITE RANDOMIZED TRIAL OF A SINGLE- VERSUS MULTI-SESSION LITERACY SENSITIVE SELF-CARE INTERVENTION FOR PATIENTS WITH HEART FAILURE. Darren A DeWalt 1; David W Baker 2; Dean Schillinger 3; Victoria Hawk 1; Bernice Ruo 2; Kirsten Bibbins-Domingo 3; Morris Weinberger 1; Aurelia Macabasco-OConnell 4; Kimberly Broucksou 1; George Mark Holmes 1; Kathleen L Grady 5; Brian Erman 1; Michael Pignone1. 1University of North Carolina, Chapel Hill, North Carolina ; 2Northwestern University, Chicago, North Carolina ; 3University of California, San Francisco, San Francisco, North Carolina ; 4University of California, Los Angeles, Los Angeles, California ; 5Northwestern University, Chicago, Illinois . (Tracking ID # 10142)

BACKGROUND: Heart failure (HF) self-care training reduces HF-related hospitalizations and appears to do so more for patients with low literacy. However, the optimal components and structure of the training are not clear. We conducted a multisite randomized trial comparing a literacy sensitive single educational session only (SS-only) with a multi-session teach to goal (TTG) educational and self-care support program, and tested whether the effects differed by literacy.

METHODS: We randomized ambulatory patients from 4 academic medical centers who had symptomatic HF (NYHA class II-IV) to: 1) a single session, face-to-face one hour educational session with a health educator and a focused curriculum of key self-care information alone (SS-only); or 2) the same single session plus a multi-session phone-based support (58 sessions over the next month and continued calls every 2 to 4 weeks for 12 months) that reinforced learning goals and behaviors (TTG). The education tools and strategy were designed to reduce literacy-related barriers to self-care. We stratified randomization by literacy using the short Test of Functional Health Literacy in Adults with inadequate and marginal defined as low literacy. The primary outcome was combined all-cause hospitalization or death. The secondary outcome was HF-related hospitalization determined by blinded adjudication of medical records. We used negative binominal regression to examine the differences between groups. We adjusted for differences in baseline HF quality-of-life, social status, and use of ACE/ARB, and tested for effect modification by literacy. We present incidence rate ratios (IRR) for all patients and stratified by literacy with IRRs less than 1 favoring TTG.

RESULTS: 605 participants were randomized: 302 SS-only and 303 TTG. Mean age was 61 years; 48% were female; 38% African-American and 16% Latino; 26% had less than a high school education; 69% had ejection fraction less than 0.45; 31% were NYHA class III or IV; and 37% had low literacy. Overall the number of all-cause hospitalizations and deaths and HF-related hospitalizations did not differ between the two groups (SS-only=224 hospitalizations and 16 deaths, with 87 HF-related; TTG=244 hospitalizations and 11 deaths, with 83 HF-related) (Table). However, low literacy was a statistically significant effect modifier for HF-related hospitalization (p=0.014), with fewer HF-related hospitalizations observed among those in the TTG group; effect modification by literacy was more modest for the combined incidence of all-cause hospitalization or death (p=0.131).

CONCLUSION: Overall, the multi-session TTG intervention and the SS-only intervention had similar effects on the incidence of all-cause hospitalization and death. However, TTG appeared to be more effective than SS-only in reducing the incidence of HF-related hospitalization for patients with low literacy, but not for those with higher

literacy. A single training session may be sufficient for those with higher literacy, but more sustained and intensive support may be required to reduce HF hospitalizations for patients with low literacy.

INFORMATION NEEDS AND SIGN-OUT UTILIZATION HABITS OF CROSS COVERING PHYSICIANS.

Robert Fogerty 1; Leora Horwitz2.
1Yale-New Haven Hospital, New Haven, Connecticut ; 2Yale University School of Medicine, New Haven, Connecticut . (Tracking ID # 10144)

BACKGROUND: Patients who are cared for by covering physicians have higher adverse event rates and increased delays to treatment. These adverse events can be the result of inaccurate or inadequate sign-out. However, the actual data needs of covering physicians, and where they obtain these data, are currently unknown.

METHODS: During a four-week period from July 7 to August 3, 2010, interns on general medical services were asked to prospectively record data about their cross cover experience during a traditional 30 hour on-call shift. Each intern was provided with a pocket card and asked to record data directly on the card, which was collected the next day. Each time the intern was contacted regarding a patient received during sign-out (one call), the intern was asked to record who initiated the contact(i.e., nursing, patient), what the situation was about (i.e. medications, test results), where the intern found the desired information (i.e. written sign-out, Electronic Medical Record[EMR]), whether all required data was located, whether the call was anticipated by the primary team, whether the call could have been anticipated by the primary team, and if the received sign-out was sufficient. Each intern was eligible to participate once during the study period.

RESULTS: A total of 14/24 (58%) of eligible interns completed data collection, with 123 unique calls recorded. Interns were able to find all desired information for 91% of calls. Information was found most often in the written sign-out (44%), followed by the EMR (24%), and verbal sign-out (21%). Questions regarding orders (25%) were most common, followed by medications (20%), plan of care (17%), and test results (11%). Interns sought information in different places depending on the questions they were asked. Interns were more likely to use the written sign-out rather than the EMR when asked about medications or test results, and were equally likely to use the written sign-out or the EMR for questions regarding orders and plan of care (P=0.01). Nursing staff were responsible for 89% of calls. Interns judged 66% of all events as possible to anticipate, yet only 40% of all events were anticipated by the primary team. Calls regarding plan of care and medications were most likely to be anticipated, whereas events regarding test results were least likely to have been anticipated (p=0.009).

CONCLUSION: Even with widespread EMR usage, covering physicians remain most likely to reference information received during physician-to-physician sign-out. With 2/3 of cross cover calls being predictable, accurate sign-out remains vital to safe patient handoff and should include an emphasis on expected overnight events.

ASSOCIATION OF HIV STATUS AND NON-AIDS COMORBID DIAGNOSES IN A COHORT OF OLDER HIV-INFECTED AND AT-RISK MEN

Katherine Krauskopf 1; Alex D. Federman 1; Grace Mhango 1; Robert S. Klein1. 1Mount Sinai School of Medicine, New York, New York. (Tracking ID # 10186)

BACKGROUND: The prevalence of non-AIDS comorbid conditions in HIV-infected individuals is rising in the United States. To-date, prevalent non-AIDS conditions have been described in specific HIV-infected populations (U.S. Veterans, for example) and factors associated with incidence of several non-AIDS conditions (for example pulmonary disease, non-AIDS malignancies) have been identified. This study defines the prevalence and incidence of several non-AIDS conditions, including cardiometabolic comorbidities, in a unique urban cohort of older men, and compares factors associated with developing these conditions in subjects with well-controlled HIV, poorly-controlled HIV and those uninfected but at-risk for HIV.

METHODS: We analyzed prospective, standardized interview and laboratory data from The Cohort of HIV At-risk Aging Mens Prospective Study (CHAMPS), a study of HIV-infected and at-risk men, 49 years of age and

older, conducted from 20012006 in the Bronx, New York (n= 643). HIV status was defined as negative if participants reported never having a diagnosis of HIV at study entry, well-controlled if patients were HIV-positive with an undetectable HIV viral load at study entry, and poorly-controlled if patients were HIV-positive with a detectable HIV viral load at study entry. Study outcome diagnoses of hyperlipidemia, hypertension, chronic liver disease and diabetes were self-reported at baseline and 6-month follow-up interviews over the study duration. Baseline prevalence of these outcomes was calculated using cross-sectional frequency analysis. Kaplan-Meier analyses were performed to determine diagnosis incidence and unadjusted hazard ratios across all three HIV status groups. Cox proportional hazard regressions were performed to determine significant differences in and factors associated with the probability of developing outcome diagnoses, adjusting for baseline age, race and use of HAART.
RESULTS: Mean age of participants was 55 years (SD 5), 53% identified as Black, mean highest grade completed was 12th (SD 3), 78% had Medicaid. Fifty-six percent (n=360) were HIV-infected at study entry. Of these, 39% had well-controlled HIV. At baseline, participants with well-controlled HIV were more likely than poorly-controlled to have had an AIDS diagnosis (53% vs. 32%, p Baseline prevalence of non-AIDS diagnoses varied significantly across study groups only for hyperlipidemia: 28% of HIV-negative participants reported hyperlipidemia vs. 33% of well-controlled HIV-infected participants and 18% of poorly-controlled participants (p 0.015). Cumulative incidence rates of hyperlipidemia were 36%, 39% and 29% (HIV at-risk group, the well-controlled group and the poorly-controlled group respectively). Cumulative incidence rates of hypertension were 20%, 22% and 21%; of chronic liver disease: 20%, 21% and 26%; and of diabetes: 15%, 16% and 13%. At 1 year, the unadjusted probability of developing hyperlipidemia was 22% (95% CI 16%-29%), 29% (95% CI 19%-68%) and 25% (95% CI 17%-32%) in the HIV at-risk group, the well-controlled group and the poorly-controlled group respectively; of developing hypertension: 10% (95% CI 4%-11%), 10% (95% CI 3%-17%) and 10% (95% CI 4%-16%); of developing chronic liver disease: 17% (95% CI 11%-28%), 12% (95% CI 5%-19%) and 22% (95% CI 15%-29%); and of developing diabetes: 10% (95% CI 5%-14%), 8% (95% CI 3%-14%), 10% (95% CI 5%-14%).

There were no statistically significant differences in the probability of developing any non-AIDS comorbidity across study groups over total study follow-up. In Cox regression models, black race was associated with probability of developing a diabetes diagnosis (HR 2.9, 95% CI 1.2-7.3, p 0.024) and age was associated with incident diagnosis of chronic liver disease (HR 0.95, 95% CI 0.9-1.0, p 0.049).
CONCLUSION: Chronic non-AIDS comorbidites were common in the HIV-infected older men in this study. HIV status, control and baseline use of HAART were not associated significantly in this cohort with incidence of reported hyperlipidemia, hypertension, chronic liver disease or diabetes. These findings support generally recommended standard screening and interventions for non-AIDS conditions in patients with poorly-controlled as well as well-controlled HIV infection, and thus highlight the growing complexity of providing effective primary care for HIV-infected individuals. These results also suggest that additional work should explore the interplay of factors beyond medication effects that contribute to the development of non-AIDS conditions in HIV-infected adults.
POTENTIAL PREVENTABILITY OF ADVERSE DRUG EVENTS INVOLVING MULTIPLE DRUGS USING PUBLIC CLINICAL DECISION SUPPORT RULES Joshua Colin Feblowitz 1; Adam Wright 1; Shobha Phansalkar 2; David W Bates3. 1Brigham &Womens Hospital, Boston, Massachusetts ; 2Brigham and Womens Hospital and Harvard Medical School, Wellesley, Massachusetts ; 3Brigham &Womens, Boston, Massachusetts. (Tracking ID # 10188)
BACKGROUND: Medications represent a major source of potential harm to patients. Dosing errors, medication

interactions, allergies and supratherapeutic effects can all lead to adverse drug events (ADEs). Unfortunately, ADEs occur frequently, negatively affecting both the quality and efficiency of medical care. The burden of ADEs is substantial; they are associated with increased length of stay, increased costs and increased mortality. The goal of this study was to determine the frequency of potential and actual ADEs involving multiple drugs in the community hospital setting.
METHODS: In a prior multi-center, retrospective cohort study, records were reviewed for 1,200 randomly selected hospitalizations (200 per site). This sample was drawn from 109,641 hospitalizations (January 2005 through August 2006) at six 100300 bed community hospitals in Massachusetts without CPOE. Overall, 180 ADEs and 552 potential ADEs were identified. We re-analyzed these data to determine the frequency of potential and actual ADEs involving multiple drugs. We defined an ADE involving multiple drugs as an injury or adverse response resulting from the administration of a combination of two or more medications. Specific categories of ADEs analyzed include those resulting from drug-drug interactions (DDIs), therapeutic duplications (TDs), drug duplication (DDs) and combined nephrotoxicity (CN). One reviewer assessed the dataset to identify ADEs involving multiple drugs and another reviewer assessed the dataset for pADEs involving multiple drugs. The primary outcome measure of this study was the frequency and type of both actual and potential ADEs involving multiple drugs. RESULTS: During the study period there were 17 ADEs involving multiple drugs (1.4 per 100 admissions). We identified instances of therapeutic duplication, drug duplication, and drug-drug interaction, including two instances where both TD and DDI occurred. Seven multi-drug ADEs involved opioids, 5 involved benzodiazepines, and 5 involved cardiovascular drugs (Table 1). In addition, 146 potential ADEs (12.2 per 100 admissions) involving multiple drugs were identified (Table 1). In contrast with ADEs, most pADEs (85.6%) involved drug duplication. Notably, 110 out of 146 potential ADEs (75.3%) involved an excess dose
of acetaminophen and, of these, 105 (95.5%) involved the use of a combination drug containing acetaminophen with an opioid. The single most common pADE was a combination of acetaminophen and acetaminophen/oxycodone (n=51).
CONCLUSION: Multi-drug adverse events represent a notable proportion of all ADEs and pADEs and a significant threat to patient safety. Actual multi-drug adverse events most commonly involved interactions between different drugs (especially opioids, benzodiazepines and cardiac medications). In contrast, the vast majority of pADEs were related to drug duplication. In addition, a very high proportion of multi-drug pADEs were associated with acetaminophen, especially acetaminophen-containing opioids. More robust measures for detection and prevention, such as computerized provider order entry (CPOE) with medication decision support are needed to identify such errors before they can result in ADEs.
Table: 1
Category ADEs PADEs Drug-drug interaction 11 17 Therapeutic duplication 7 3Drug duplication 1 125 Combined nephrotoxicity 0 2 Total 19 147 Unique Events 17 146
CONTINUITY OF CARE: ASSURING POST-DISCHARGE WARFARIN MONITORING Denice Arthur 1; Chepkorir Maritim 1; Brent Petty2. 1The Johns Hopkins Hospital, Baltimore, Maryland; 2Johns Hopkins University School of Medicine, Baltimore, Maryland. (Tracking ID # 10190)
BACKGROUND: Warfarin is among the drugs most frequently associated with adverse effects. The interface between inpatient status and discharge to home is a transition point where coordination of follow-up for patients discharged on warfarin is essential. Successful coordination of this transition is also relevant to the emphasis on improved anticoagulation care as a national patient safety goal. Errors at this transition of care can have catastrophic results.
METHODS: We reviewed the records of all adult patients discharged our hospital over a 6-week period with warfarin listed as a discharge medication. At eight days or more after discharge, we searched the hospitals laboratory test database to see if the patient had been back to a hospital clinic where prothrombin time/INR

testing had been conducted. When such test results were not found, we contacted the patients follow-up provider (using a telephone script for systematically collecting data) to determine if the patient had been tested for prothrombin time/INR within seven days following discharge and if the result was available.
RESULTS: A total of 323 patients were reportedly discharged on warfarin. Of these, 72 were excluded (22 who were discharged to rehab, long-term care or prison, 19 whose providers offices did not return our calls, 13 who were not actually discharged on warfarin, 10 who had died, 5 whose follow-up provider was not adequately identified in the record, and 3 international patients who had returned to their foreign countries). Of the remaining 251 patients, 147 (59%) had a documented INR result within seven days of discharge. Of the 104 patients who did not have an INR within seven days of discharge, 39 (38%) failed to make a follow-up appointment and 18 (17%) failed to keep their appointment for follow-up testing. Therefore, 55% of failures were related to patient-

controlled factors. For 43% of the failures, either the clinic visit occurred without an INR being checked or it occurred more than seven days after discharge. An unintended benefit of the telephone contact was improved relationships with post-discharge providers, as we found that some providers were not already aware of the patients hospitalization and the need for timely follow-up.
CONCLUSION: Our data demonstrate a need for improved transition of care for patients discharged on warfarin. Implementing changes in practice to achieve this goal will decrease the risk of adverse events associated with warfarin therapy, whether they be related to subtherapeutic or supratherapeutic results. In particular, interventions to increase the awareness in patients of the existence and importance of arranged follow-up testing appear most likely to improve performance in this area.
BARRIERS TO BREAST CARE FOR UNDERSERVED WOMEN Pamela Ganschow 1; Joann Elmore 2; Arthur Evans 3; Monica Peek1. 1Rush University Medical Center/Stroger Hospital, Chicago, Illinois ; 2University of Washington, Seattle, Washington ; 3Weil Medical Center, New York, New York . (Tracking ID # 10196)
BACKGROUND: Underserved women are at increased risk for diagnostic delays during evaluation of breast abnormalities. Patients perceptions of reasons for these delays are poorly understood. The objective of this study was to identify patients perceptions of evaluation time and barriers to care, and to examine the association between identified barriers and delay time, among women with suspicious breast findings who use a safety-net health care system.
METHODS: We conducted a prospective study of 270 predominantly English- and Spanish-speaking women (minimum age 30 years) undergoing non-operative breast biopsy between 2006 and 2009 at a large public hospital. The hospital receives referrals from over 210 affiliated primary care clinics serving uninsured and under-insured patients. At the time of biopsy or before disclosure of results, in-person interviews were conducted to gather information on demographics, socioeconomic status, clinical history, self-reported personal and system reasons for delays in care, and patients perceptions of their evaluation time. Time to biopsy was defined as the time from initial detection of the breast abnormality to initial biopsy and evaluation time was defined as the time from first contact with the health care system to the date of initial biopsy. The clinical history including date and mode of detection (e.g., self- or image-detected) and all healthcare visits for the breast problem were verified through medical record abstraction. We used a CDC recommended 60-day benchmark for defining appropriate evaluation time. Univariate and multivariate analyses with backwards elimination were performed using quantile regression to examine differences in median time to initial biopsy by patient characteristics, mode of detection, and personal and system reasons for not seeking evaluation sooner.
RESULTS: The mean age was 51 years; 49% were Black, 36% were Hispanic, 74% were uninsured, and 39% reported no access to a regular provider. Among the 270 women, 47% had self-detected breast abnormalities and 53% had abnormalities detected by imaging. Median time to biopsy was 120 days (IQR: 62202) and median evaluation time was 92 days (IQR: 42174). These median times did not differ significantly by mode of

detection. For 64% of women, evaluation was delayed by >60 days and over 50% of these women did not perceive this as too long. The most common personal reasons for delays were fear of having breast cancer (46%), fear of evaluation or treatment (46%), financial concerns or lack of insurance (43%), and belief that the problem was not serious (37%). The most common system reasons
reported were difficulties obtaining a clinic appointment (40%) and having one or more appointments rescheduled by the doctor or clinic (36%). After controlling for covariates, only the system reason of having appointments rescheduled by the doctor or the clinic was associated with a statistically significant increase in the median time to initial biopsy of 54 days (95% CI: 3177 days; p<0.001). Having a family history of breast cancer was associated with a statistically significant decrease in the median time to biopsy of 36 days (95% CI: 12 60 days; p=0.004).
CONCLUSION: Significant diagnostic delay times persist among underserved women with breast abnormalities. While many barriers to care were reported by women, few were associated with a longer time to biopsy. Potential interventions to decrease delay times include alleviating system factors that lead health care facilities to reschedule patient appointments and increasing patient awareness of acceptable evaluation times for breast problems through messaging and education.
SERUM CALCIUM LEVELS ARE ASSOCIATED WITH NOVEL CARDIOMETABOLIC RISK FACTORS IN THE POPULATION-BASED COLAUS STUDY Idris Guessous 1; Olivier Bonny 2; Fred Paccaud 3; Vincent Mooser 4; Gerard Waeber 5; Peter Vollenweider 2; Murielle Bochud3. 1Unit of population epidemiology, Geneva, N/A ; 2Lausanne University Hospital, Lausanne, N/A ; 3University Institute of Social and Preventive Medicine, Lausanne, N/A ; 4GlaxoSmithKline, Philadelphia, Pennsylvania ; 5Lausanne University Hospitals, Lausanne, N/A . (Tracking ID # 10201)
BACKGROUND: Increased serum calcium concentration has been associated with high blood pressure, impaired glucose tolerance, and dyslipidemia. More recently, increased serum calcium concentration has been described as a feature of the metabolic syndrome. Cardio-metabolic components not classically included in the metabolic syndrome have been associated with the risk of cardiovascular disease and include components related to adiposity, blood lipids, and insulin resistance. In addition, factors related to inflammation and oxidative stress have been recently associated with the metabolic syndrome. For example, observations suggest that serum levels of uric acid, homo-cysteine or gamma-glutamyltransferase might be linked to the metabolic syndrome. While associations of serum calcium with the conventional components of the metabolic syndrome on one hand, and of non-conventional cardio-metabolic risk factors with the metabolic syndrome on the other hand have been explored, the relationship between serum calcium and non-conventional cardio-metabolic risk factors has not been characterized in the general population. We analyzed the association of albumin-corrected serum calcium with conventional and a broad range of non-conventional cardio-metabolic risk factors in the Swiss population-based CoLaus study. METHODS: The CoLaus study is a population-based study including Caucasians from Lausanne, Switzerland. The metabolic syndrome was defined using the Adult Treatment Panel III criteria. Cardio-metabolic components that are not included in the metabolic syndrome were defined as non-conventional cardio-metabolic risk factors and classified into the following four groups: (i)Adiposity: fat mass (kg), leptin (ng/mL);(ii)Blood lipids: LDL-cholesterol (mmol/L), LDL size (angstrm), apolipoprotein B (mg/dL); (iii)Insulin resistance: fasting insulin (microU/ mL), adiponectin (microg/mL); (iv)Inflammation-oxidative stress: ultra-sensitive CRP (mg/L), serum uric acid (micromol/L), homocysteine (micromol/L), gamma-glutamyltransferase (UI/L). For the non-conventional cardio-metabolic risk factors score, subjects in the upper tertile of the risk factor were assigned a value of 1, whereas subjects in the first and second tertiles were assigned a value of 0 for each non-conventional

cardio-metabolic risk factor positively correlated with cardiovascular disease, and vice versa for non-conventional cardio-metabolic risk factors negatively correlated with cardiovascular disease. Positive and negative correlations were based on the existing literature. Only non-conventional cardio-metabolic risk factors that showed a statistically significantly trend with calcium in quintiles analyses were entered into the non-conventional cardio-metabolic risk factors score. We used adjusted standardized multivariable regression to compare the association of each cardio-metabolic risk factor with albumin-corrected serum calcium. We assessed associations of albumin-corrected serum calcium with the cumulative number of non-conventional cardio-metabolic risk factors.
RESULTS: We analyzed 4,231 subjects aged 35 to 75 years. Albumin-corrected calcium levels increased linearly with the number of conventional cardio-metabolic risk factors (p for linear trend <0.001) (figure 1), independently of BMI. Respectively 465 (11.0%), 783 (18.5%), 837 (19.8%), 750 (17.7%), 592 (14.0%), 443 (10.5%), 249 (5.9%), and 112 (2.6%) had 0, 1, 2, 3, 4, 5, 6, or 7+ non-conventional cardio-metabolic risk factors. The mean number of non-conventional cardio-metabolic risk factors per subjects was 2.7 (SD=1.83). Albumin-corrected calcium levels increased linearly with the number of non-conventional cardio-metabolic risk factors (p for linear trend <0.001) (figure 2), independently of the metabolic syndrome and BMI. Among conventional and non-conventional cardio-metabolic risk factors, the strongest positive associations were found for factors related to oxidative stress (acid uric, homocysteine and gamma-glutamyltransferase). Adiponectin had the most important negative association with albumin-corrected serum calcium.
CONCLUSION: Serum calcium was associated with the metabolic syndrome and with non-conventional cardio-metabolic risk factors independently of the metabolic syndrome. Associations with acid uric, homocysteine and gamma-glutamyltransferase were the strongest. Although the associations with blood pressure, insulin resistance and dyslipidemia have been previously described, we are not aware that this was reported for serum uric acid, homocysteine, or gamma-glutamyltransferase levels in a large-scale population-based sample. These novel findings suggest that serum calcium levels may be associated with cardiovascular risk via oxidative stress.
ADVANCES IN MEASURING CULTURALLY COMPETENT CARE: A CONFIRMATORY FACTOR ANALYSIS OF THE CAHPS-CC IN A SAFETY-NET POPULATION Hilary Seligman 1; Rachel Judith Stern 2; Alicia Fernandez 1; Elizabeth Jacobs 3; Torsten Neilands 1; Robert Weech Maldonado 4; Adam Carle 5; Judy Quan1.

4University of Alabama at Birmingham, Birmingham, Alabama ;
5Cincinnati Childrens Hospital Medical Center, Cincinnati, Ohio . (Tracking ID # 10205)
BACKGROUND: The Agency for Healthcare Research and Quality (AHRQ) developed the Consumer Assessment of Healthcare Providers and Systems (CAHPS) as a patient-administered assessment of healthcare quality in diverse settings. Health plans (public and private) are required to report CAHPS data to the federal government as a quality of care metric. While CAHPS has been extensively validated among insured patients, it is less clear how it performs with ethnically diverse, uninsured populations. Adding a culturally competent care domain makes CAHPS more relevant to diverse, uninsured, safety-net, and other vulnerable populations, and may inform the development of interventions to reduce healthcare inequalities. Therefore, the Consumer Assessment of Healthcare Providers and Systems Cultural Competency survey (CAHPS-CC) was developed as a supplement to CAHPS, with the intention that it would be broadly administered with the CAHPS survey. We examined CAHPS-CCs suitability for administration in a safety-net setting.
METHODS: We performed exploratory factor analyses and confirmatory factor analysis for ordered categorical measures of the CAHPS-CC to describe the measurement structure of the question set and identify subscales. Our sample included 600 patients with type 2 diabetes receiving primary care in safety-net clinics in Chicago and the San Francisco Bay Area. We used Cronbachs alpha to assess internal consistency and multinomial

logistic regression to assess the extent to which culturally competent care explained global physician ratings. RESULTS: A seven-factor model demonstrated satisfactory fit (RMSEA=0.43; CFI=0.96; TLI=0.96). Three domains showed excellent internal consistency positive provider communication (Cronbach alpha=.82),

trust (Cronbach alpha=.77), and health promotion (Cronbach alpha =.72). Three domains showed reliability below our a priori cut point equitable treatment (Cronbach alpha=.69), alternative medicine (Cron-bach alpha=.52), and shared decision-making (Cronbach alpha=.51) but these were all 2-item scales (for which lower scores are expected). The negative provider communication and equitable treatment domains had adequate reliability among English speakers but poor reliability among Spanish speakers. CAHPS-CC domains accounted for 5.9% (alternative medicine) to 26.2% (positive communication behavior) of the variance in global physician ratings.
CONCLUSION: CAHPS-CC is suitable for broad-scale administration among patients, particularly English-speakers, receiving care in safety-net settings. The provision of culturally competent care is instrumental to patient satisfaction in this population, as demonstrated by the high impact of CAHPS-CC subdomains on global physician ratings. CAHPSCC may be used to target quality-improvement efforts focused on providing culturally competent care.
DEVELOPMENT AND VALIDATION OF THE SAFETY NET MEDICAL HOME SCALE Jonathan Birnberg 1; Melinda Drum 1; Elbert Huang 1; Lawrence Casalino 2; Sarah Elizabeth Lewis 1; Anusha Vable 3; Hui Tang 4; Quinn Michael 7; Deborah Burnet 1; William Summerfelt 5; Marshall Chin1.
1University of Chicago, Chicago, Illinois ; 2Weil Medical College, New York, New York ; 3University Of Chicago, Chicago, Illinois ; 4University of Chicago, CHICAGO, Illinois ; 5Advocate Health System, Oak Brook, Illinois . (Tracking ID # 10217)
BACKGROUND: Existing tools to measure patient centered medical home (PCMH) adoption are not designed for longitudinal research evaluations in safety-net health centers. Therefore, we developed the Safety Net Medical Home Scale (SNMHS).
METHODS: The study sample included 65 safety net clinics in5 states (ID, CD, MA, OR, PA). To create our scale, we began with the Commonwealth Fund Organizational Survey of Federally Qualified Health Centers. Surveys were completed by clinic leadership with help from other clinic staff. The survey includes 92 items covering access to care, language services, quality improvement, and patient information systems. Using a consensus process, we mapped survey items onto the domains of the NCQA Physicians Practice Connections-PCMH TM
instrument and an External Coordination domain. Next, we identified core items representing greater importance to the PCMH concept. Core items were differentially weighted by rescaling these items to have potential range of 0 to 2, while all other items were rescaled with a potential range from 0 to1. Rescaled weighted items in the domain were summed, and the total was rescaled to have a potential range 0 to100 (worst to best). The total SNMHS score was the mean of the 6 domain scores. To test for reliability, we calculated Cronbachs alpha within each domain and for the total scale. We tested for convergent validity with two survey tools. The Assessment of Chronic Illness Care (ACIC) measures adoption of the Chronic Care Model. The Patient Centered Medical Home Assessment (PCMH-A) measures PCMH readiness. We correlated the total SNMHS score with the total ACIC and PCMH-A scores. RESULTS: Response rate was 100%. The conceptual mapping yielded 52 items (16 core items) organized into six domains: Access and Communication (12 items, 4 core), Patient Tracking and Registry (7 items, 3 core), Care Management (8 items, 2 core), Test and Referral Tracking (4 items, 2 core), Quality Improvement (10 items, 2 core), External Coordination (11 items, 3 core). The mean SNMHS score was
61SD 13. Among the subscales, External Coordination (6616) and Access and Communication (6514) had the highest mean scores, while Quality Improvement (5517) and Care Management (5516) had lower mean scores.

The SNMHS demonstrated high internal consistency reliability: Total Score (Cronbachs alpha=0.84), Access and Communication (alpha=0.68), Patient Tracking and Registry (alpha=0.89), Care Management (alpha=0.60), Test and Referral Tracking (alpha=0.73), Quality Improvement (alpha=0.73), External Coordination (alpha=0.78). Total SNMHS score correlated with the total ACIC score (R=0.64, p<0.001) and the total PCMH-A score (r=0.56, p<0.001). CONCLUSION: The Safety Net Medical Home Scale provides a comprehensive measurement of medical home adoption and demonstrated reliability and convergent validity.

MANAGEMENT OF UNCONTROLLED HYPERTENSION IN THE OUTPATIENT SETTING Salma Baksh 1; Ahmed Shawkat 1; Christian Glaser 1; Ahad Lodhi 1; Cleopatra Laicer 1; Alyson 1; Dina CapalongoDobracki2. 1Crozer Chester Medical Center, Upland, Pennsylvania; 2Crozer Chester Medical Center Crozer Chester Medical Center, Upland, Upland, Pennsylvania, Pennsylvania. (Tracking ID # 10220)

BACKGROUND: Hypertension is an important cause of morbidity and mortality. Approximately 65 million Americans are affected. It causes increased disease burden including stroke, myocardial infarction, heart failure and chronic kidney disease. The JNC guidelines recommend strict blood pressure control especially in patients with diabetes and chronic kidney disease. Although weight loss, exercise and diet modification is encouraged medical therapy is frequently required. Up to one fourth of American adults are on medications to treat hypertension.

METHODS: We retrospectively collected data from our office electronic medical records (EMR). We screened and included all patients seen between January 2008 and March 2010 with a diagnosis of hypertension and one uncontrolled blood pressure measurement (>140/90) during a single office visit. Patients with a normal blood pressure, newly diagnosed hypertension and patients in the EMR, not seen by our practice were excluded.

RESULTS: 207 charts were reviewed and 161 patients included. 59% were female and 41% were male. Mean BMI was 34.1. Out of 161 patients 69 (43%) had stage 2 hypertension. 25% (n=40) had diabetes, 9% (n=15) had chronic kidney disease and 7% (n=11) had congestive heart failure. 87% of diabetics, 80% of patients with chronic kidney disease and 82% of patients with congestive heart failure were on Angiotensin Converting Enzyme-Inhibitors or Angiotensin Receptor Blockers. 64% patients with congestive heart failure were on beta-blockers. Blood pressure was not re-checked by a physician in 54% of all patients and 33% of stage 2 hypertensives. Hypertension was not addressed in 19% of the total study group and in 12% of patients with stage 2 hypertension. Of the 81% of patients in whom hypertension was addressed, 24% were non compliant, 7% had life style modification recommendations, 40% had no intervention documented and only 17% had a follow up appointment within 2 months. On reviewing charts of patients with stage 2 hypertension (n=69), it was noted that 17 patients were inappropriately on 1 (n=15) or zero (n=2) medications for their blood pressure and 52 were on 2 or more antihypertensive medicines. CONCLUSION: We conclude that blood pressure is not re-checked at each visit by physicians. Stage 2 hypertensives were not identified, received in-adequate therapy and were not followed up appropriately. Appropriate anti-hypertensive medications were being used for the co-morbid conditions, but not all the time.

SUBSTANCE ABUSE TREATMENT OUTCOMES IN PATIENTS WITH OPIOID DEPENDENCE AND CHRONIC PAIN IN AN OFFICE BASED BUPRENORPHINE TREATMENT PROGRAM Aaron Fox1; Nancy L. Sohler 2; Angela Giovanniello 3; Chinazo Cunningham1. 1Division of General Internal Medicine, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York ; 2Sophie Davis School of Biomedical Education, City University of New York, New York, New York ;
3Department of Family and Social Medicine, Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York . (Tracking ID # 10228)

BACKGROUND: Patients with substance use disorders report high levels of physical pain. However, current

data is conflicting as to whether chronic pain affects substance abuse treatment outcomes. Office based buprenorphine therapy is a new paradigm for treatment of opioid dependence, and the impact of co-morbid chronic pain on buprenorphine treatment outcomes is not well understood. Clinical guidelines cite chronic severe pain as a relative contraindication to buprenorphine treatment, since buprenorphine is a partial opioid agonist. Instead, treatment with methadone, a full opioid agonist, is recommended for patients with chronic severe pain. However, evidence supporting these recommendations is lacking. To examine the association between pain and buprenorphine treatment outcomes, we compared the proportion of treatment failures in opioid dependent patients with and without chronic pain who received primary care based buprenorphine treatment.
METHODS: We conducted a longitudinal cohort study of opioid-dependent individuals who initiated buprenorphine treatment at an urban community health center. Participants were interviewed at baseline, and 1, 3, and 6 months after initiating buprenorphine treatment. Questionnaires included demographic information, substance use, depressive symptoms, health status, and presence and severity of pain. The primary outcome was treatment failure, defined as self-reported use of opioids (heroin, methadone, or opioid analgesics) in the 30-day period preceding the 6 month follow-up visit. The main predictor variable was presence of chronic pain, defined as a score of 5 or greater on a scale from 110 on the Brief Pain Inventory at every study visit. We used logistic regression models to test whether treatment failure was associated with chronic pain, adjusting for baseline opioid use.
RESULTS: Of 84 participants, the median age was 44, and most were male (73%), Hispanic (69%), unstably housed (61%), and had used heroin in the 30 days prior to initiation of buprenorphine (67%). These characteristics were similar in the 31 (37%) participants with chronic pain and the 53 without chronic pain. The groups with and without chronic pain differed on a number of factors measured at baseline, including history of injection drug use (68% vs. 42%, p<.05), problematic alcohol use (50% vs. 15%, p<.01), sedative use (29% vs. 8%, p<.01), and opioid analgesics use (48% vs. 15% p<.01). Of these covariates, only sedative use was associated with treatment failure in bivariate analysis. At 6 months of follow-up, 25 participants (30%) experienced treatment failure. Adjusting for baseline opioid use, there was no difference in opioid use at 6 months between those with and without chronic pain (OR=1.05, 95% CI: 0.37 - 3.00). Further adjustment for other covariates associated with treatment failure, such as sedative use at baseline, did not alter this finding.
CONCLUSION: Over one-third of participants in this cohort of opioid dependent patients receiving buprenorphine treatment at an urban health center experienced chronic pain. Despite greater use of other substances at baseline and additional factors that may predict treatment failure, substance abuse treatment outcomes did not appear to differ between patients with chronic pain and those without chronic pain. Our study was limited by its lack of a comprehensive measure of pain severity, relatively small sample size, and limited power to detect small difference between groups. While these findings are exploratory, they suggest that buprenorphine treatment for opioid dependence may be effective even in patients with chronic pain. Future research that examines buprenorphine treatment outcomes among patients with chronic pain is warranted.
A METHOD AND KNOWLEDGE BASE FOR AUTOMATED INFERENCE OF PATIENT PROBLEMS FROM STRUCTURED DATA IN AN ELECTRONIC MEDICAL RECORD Adam Wright 1; Justine Pang 1; Joshua Colin Feblowitz 1; Francine Maloney 2; Allison Wilcox 4; Harley Ramelson 1; Louise Schneider 1; David Bates1. 1Brigham &Womens Hospital, Boston, Massachusetts; 2Partners HealthCare, Boston, Massachusetts.
(Tracking ID # 10232)
BACKGROUND: An accurate and up-to-date problem list represents the cornerstone of the modern electronic health record (EHR). Problem lists serve a wide variety of roles in facilitating care by providing a succinct clinical picture of each patient, facilitating communication, and enabling the delivery of clinical decision support (CDS). Yet, despite their importance, problem lists are often inaccurate, incomplete and poorly maintained. Given this fact, researchers have turned to a variety of alternate sources for problem information, using natural language

processing (NLP) techniques to interpret free-text patient information and data mining strategies to identify data predictive of patient problems. The primary goal of this study was to develop and validate methods of automatically inferring problems from clinical and billing data and to generate a knowledge base designed for this purpose. METHODS: We identified target conditions and designed and validated a set of rules for identifying patient problems based on medications, laboratory results, billing codes and vital signs. In designing these rules, we incorporated a previously-developed database of medication-problem and laboratory-problem associations created using data mining techniques. A preliminary list of problems was chosen on the basis of several criteria including: 1) pay-for-performance (P4P) initiatives at the study site, 2) problem-dependent CDS rules in the sites EHR and 3) relevant medication-problem and laboratory-problem associations identified during the previous project. A preliminary set of rules was then developed for testing with input from a physician panel. We then tested multiple versions of each rule on a training set of 100,000 patient records to assess their performance and calculated the specificity, sensitivity and positive and negative predictive values for each. Based on these results, the panel selected a set of final rules, which was validated on an independent sample of 100,000 records.
RESULTS: Seventeen rules were developed for inferring patient problems. Final rules used coded and free-text problem recognition as well as: billing codes, medications, laboratory data and/or vitals to infer patient problems. When applied to the training set, the average sensitivity and PPV for all seventeen rules was 86.4% and 91.1% respectively. Subsequent analysis using an independent validation set showed high sensitivity (average: 83.9%) and PPV (average: 91.7%) for

most rules. For each problem, we also assessed the accuracy of two simpler classes of rules: problem list-only and billing code-only rules. The results of this analysis showed that these rules were more sensitive than the problem list alone and had better PPV than billing codes alone. CONCLUSION: We developed and validated a set of rules that identifies patients likely to have a particular problem. These data show that problems can be accurately inferred, and that the performance of the
rules exceeds that of standard sources. These rules had high sensitivity and specificity and, in our population, also high PPV and NPV. Problem inference rules such as ours have a variety of potential applications, including: alerting clinicians to potential gaps in the problem list, identifying research cohorts, calculating quality measures, selecting patients for care management programs and designing clinical decision support.
TEMPORO-SPATIAL SURVEILLANCE OF INFLUENZA-LIKE-ILLNESS: PRELIMINARY RESULTS FROM THE IDAHO INFECTIOUS DISEASE REPORTING NETWORK Andy Wilper 1; William Weppner 2; Kai Elgethun 3; Denny Stevens2. 1University of Washington School of Medicine, Boise, Idaho ; 2Boise VAMC, Boise, Idaho ; 3Boise State University, Boise, Idaho . (Tracking ID # 10243)
BACKGROUND: Current influenza like illness (ILI) monitoring in Idaho is based on syndromic surveillance using laboratory data combined with periodic person-to-person reports collected by state workers. This system also relies on voluntary reporting from physicians, schools and other institutions. Electronic medical records (EMRs) offer a method of obtaining data in an automated fashion. The Veterans Administration EMR (CPRS) captures real-time visit information, vital signs, ICD-9, pharmacy and lab data. EMR surveillance has been utilized for syndromic surveillance on a regional level. Funds supporting expansion of EMRs offer increased ability for use in biosurveillance. The addition of temporo-spatial modeling may improve identification of clusters of cases. This abstract reviews our efforts to develop a real time system of
identifying ILI in Idaho using VA data and temporo-spatial techniques. METHODS: The Boise Veterans Affairs Medical Center (VAMC) provides care to over 20,000 veterans living in Idaho with clinics in Boise, Caldwell, Twin Falls, Salmon, ID and Burns, OR. Using retrospective data from the Veterans Integrated Service Network 20 (VISN 20) data warehouse for the 20082009 influenza season, we identified ILI cases from these clinics using ICD-9 codes collected as weekly counts. Duplicates and incompletes were removed; zip code was

extracted; clusters less than 5 per zip code were suppressed. We used SatScan v9.0.1 for cluster analysis with MonteCarlo simulation for an expected incidence based on distribution of sample overtime and space; geographic extent of cluster was not limited. We used ArcMap 10 for visualization based on US Census Map data. The VA Puget Sound IRB approved this study.
RESULTS: We identified one primary and one significant secondary cluster ($p<0.05$) of ILI (Figure 1). The relative risk was 7.8 for ILI in the primary cluster identified in southeast Idaho over a month-long period 7/17/09 to 8/20/09. The secondary cluster in west central Idaho occurred over a shorter two week period in January. These results were

shared with Idaho Public Health District directors, who confirmed the existence of an ILI cluster in southeast Idaho; the site of the primary
cluster. We sampled a small percent of the state population; women and children are underrepresented.
CONCLUSION: Retrospective data obtained from VA electronic health records appears to be useful in locating ILI outbreaks in space and time. Further work is needed to evaluate the ability of our system to identify outbreaks in real time, and to determine the extent to which our system may complement existing surveillance techniques. Temporo-spatial modeling may also have applications in monitoring the spatial distribution of the incidence and control of chronic diseases.
WHAT ACCOUNTS FOR THE GAP: THE CONTRIBUTION OF DIFFERENCES IN PATIENT PREFERENCE AND CLINICAL APPROPRIATENESS TO RACIAL DIFFERENCES IN PERFORMANCE ON AMBULATORY CARE QUALITY MEASURES Muriel Jean-Jacques 1;
Stephen Persell 1; Jason Thompson 1; Romana Hasnain-Wynia 1; David Baker1. 1Northwestern University, Chicago, Illinois. (Tracking ID # 10248)
BACKGROUND: The Institute of Medicine has defined healthcare disparities as racial or ethnic differences in healthcare that are not due to differences in clinical appropriateness or patient preferences. However, it is usually impossible to distinguish healthcare differences from true disparities in clinical practice because we lack sufficient data on clinical appropriateness and patient preferences. As part of the UPQUAL (Using Precision Performance Measurement to Conduct Focused Quality Improvement) initiative, simple tools were introduced into the electronic health record (EHR) at an urban academic general internal medicine practice to allow physicians to efficiently enter medical or patient reasons why quality measures are not satisfied (medical and patient exceptions)
into coded fields of the EHR. This provided a unique opportunity to examine the contribution of patient preference and clinical appropriateness to racial differences in the receipt of healthcare services.
METHODS: We examined differences in the percentage of black and white patients with documented medical or patient exceptions for 12 ambulatory care quality measures as of January 1, 2011. The quality measures addressed coronary heart disease, hypertension, diabetes, and the receipt of preventive services. Medical exceptions included medical contraindications to care guidelines (e.g. drug intolerance). Patient exceptions included patient refusals. We calculated performance for each quality measure with and without the incorporation of data on medical and patient exceptions. Comparisons between white and black patients were done using Pearsons chi-square test.
RESULTS: Among black patients, the rates of documented medical or patient exceptions ranged from 1.1% (screening or treatment for diabetic nephropathy) to 11.9% (pneumococcal vaccination if >or=65 years old). Among white patients, the range was 0.8% (screening for cervical cancer) to5.6% (LDL control in patients with diabetes). The percentage of patients who declined recommended care differed between black and white patients for 2 measures: cervical cancer screening (1% vs. 0.5%, respectively; p=.03) and pneumococcal

vaccination (11% vs. 3%; p<.001). The percentage of patients with documented medical exceptions differed between black and white patients for 2 measures: antiplatelet therapy for patients with coronary heart disease (4% vs. 2%; p=.03) and pneumococcal vaccination(0.7% vs. 0.1%; p=.003). Without the incorporation of data on clinical appropriateness and patient preference, performance for pneumococcal vaccination was significantly lower for black vs. white patients (82% vs.

91%, p<.001); when documented medical and patient reasons were included in the numerator, performance was identical (94%). The incorporation of medical and patient exceptions did not affect racial differences in performance for other measures.

CONCLUSION: Overall, the rates of patient and medical exceptions were low with few racial differences. This suggests that differences in patient preference and clinical appropriateness are relatively small contributors to racial differences in performance for most ambulatory care quality measures. However, blacks were much more likely to decline pneumococcal vaccination, and accounting for this significantly affected the measured racial difference in performance. A set of simple tools can facilitate the capture of data on clinical appropriateness and patient preference into coded fields of the EHR, and this approach may help us to better understand whether apparent differences in care are due to either of these factors.

RELATIONSHIPS BETWEEN SOCIAL RESOURCES AND HEALTHFUL BEHAVIORS: DOES AGE MATTER?

Kristina Lewis 1; Matthew Gillman 2; Elaine Puleo 3; Mary Greaney 2; Gary Bennett 4; Karen Emmons2. 1Harvard Medical School, Department of Population Medicine, Reading, Massachusetts ; 2Harvard University, Boston, Massachusetts ; 3University of Massachusetts, Amherst, Massachusetts ; 4Duke University, Durham, North Carolina . (Tracking ID # 10251)

BACKGROUND: The benefits of healthful eating and physical activity accrue to people of all ages. While greater access to social resources is associated with these behaviors, whether the associations differ by age is unknown.

METHODS: We analyzed data on 2440 participants, age 1893 years, using baseline survey data from Healthy Directions, an urban primary care-based multiple risk behavior intervention trial. We examined cross-sectional relationships between participants social resources and their self-reported total weekly physical activity and daily fruit and vegetable intake. We measured social resources using responses to 9 items (each on a 5-point Likert scale) from the Chronic Illness Resources Survey (CIRS), representing the surveys organizational, friends and family and neighborhood subscales. We measured physical activity using items from the CDCs Behavioral Risk Factor Surveillance Survey, and fruit and vegetable intake using the National Cancer Institutes 5 A Day for Better Health tool. We then used multivariable linear regression, adjusted for sex, race, education, income, BMI and self-reported health status, and evaluated associations overall and within 4 age groups: 1834, 3549, 5064 and 65+ years. RESULTS: Among the 2440 participants, 66% were female; 45% were non-white, and 60% had at least a college degree. Mean (SD) for age was49.4 (15) years, for physical activity was 346 (304) minutes/week, for daily fruit and vegetable intake was 3.4 (2.4) servings, and for CIRS score was 9.8 (5.7) on a 036 point scale. CIRS scores were slightly lower among older than younger adults (see Table, p=0.04). In multivariable analyses, CIRS score was directly associated with total physical activity(14.8 additional minutes of exercise/week per 1-point increment in CIRS score [95%CI 12.6-17.0]) and with fruit and vegetable intake (0.11 additional servings/day [95%CI 0.09 - 0.13]). We did not observe effect modification of the association of total CIRS score with physical activity by age group (interaction p=0.83), but the association for fruit and vegetables did differ by age group (see Table, interaction p=0.04). CONCLUSION: Greater support from local organizations, friends, family members, and neighbors was associated with higher physical activity levels and fruit and vegetable intake. Among older participants, CIRS scores were lower and associations of CIRS score with fruit and vegetable intake were stronger. Thus a need may exist for more health promotion programs that improve access to social resources, especially in middle-age and older adults.

PHYSICIAN COMMUNICATION BEHAVIORS DIFFER BY BMI KimberlyA. Gudzune 1; Mary Catherine Beach 1; Lisa A Cooper1. 1The Johns Hopkins University School of Medicine, Baltimore, Maryland. (Tracking ID # 10253)

BACKGROUND: Physicians weight bias may contribute to obesity-related health disparities by impairing patient-physician communication. However, whether these negative attitudes influence physicians interpersonal communication during patient encounters is unknown. Previous studies have shown that patient-centered communication behaviors are positively associated with adherence and satisfaction, while more paternalistic or biomedical behaviors demonstrate the opposite. In this study, we examined the relationship between patient body mass index (BMI) and physician communication behaviors. Given the psychosocial origins of obesity bias, we hypothesized that higher patient BMI would be associated with
decreased patient-centered communication behaviors including rapport building and patient counseling, while biomedical behaviors like data gathering would not be influenced by a patients weight status. METHODS: We used baseline data from the Patient-Physician Partnership Study. The study sample included 40 urban primary care physicians and 226 of their patients. Each patient had a patient-physician encounter audio-taped, which was then analyzed using the Roter Interaction Analysis System to determine counts of communication behaviors. These encounters were a part of ongoing care. The outcomes were physician behaviors including data gathering, rapport building and patient counseling. The independent variable was measured patient BMI. In order to account for clustering of patients by physician, we used multilevel Poisson regression models to calculate incidence rate ratios evaluating the association between BMI and the physician communication behaviors. All models were adjusted for

patient age, patient sex, patient race, number of co-morbidities, as well as physicians number of years in practice and specialty. Given the multiple comparisons, we defined a significant p-value to be RESULTS: The mean (SD) patient BMI was 32.8 (8.0) kg/m2. Patients mean (SD) age was 61.7 (12.2) years with 65% female and 60% black, while physicians were 54% female and 53% white. Mean (SD) visit length was 15.5 (7.2) minutes and did not vary significantly by BMI. Table 1 shows that physicians data gathering behaviors were similar across BMI groups. However, physicians demonstrated less rapport building with the overweight and obese groups. Physicians
also provided less patient counseling for these higher BMI groups as compared to the normal range group, especially in the lifestyle/ psychosocial realm.

CONCLUSION: We found that physicians demonstrated fewer patient-centered behaviors including rapport building and counseling to patients with overweight and obesity. As these patient encounters were part of ongoing clinical care, the limited rapport building and counseling may suggest an impaired patient-physician relationship and reduced quality of care for a variety of health outcomes between obese patients and their primary care physicians.

THE IMPACT OF HEALTH INSURANCE REFORM ON INSURANCE SWITCHES: ARE WE CHURNING? Karen Freund 1; Amresh D Hanchate 1; Alexis P Isabelle 1; Richard Kalish 1; Alok Kapoor 1; Sharon Bak 1; Marc Flore 1; Rebecca Grochow 1; Swati Shroff 1; Tracy Battaglia1.

1Boston University, Boston, Massachusetts. (Tracking ID # 10272)

BACKGROUND: The intent of health insurance reform is to improve care through the expansion of access to care. In 2006 the Massachusetts Health Reform Legislation sought to improve access to care by increasing insurance coverage. In order to address the impact of the 2006 legislation on access to care, we must first characterize the impact of the legislation on insurance coverage and stability. To this end we compared 6 categories of insurance coverage (Private, Medicare, Medicaid, Commonwealth Care, other Government,

uninsured) and the frequency of insurance switches between these categories before and after insurance reform. METHODS: We analyzed billing data from 4 Community Health Centers around a specific health care event that required ongoing health care utilization, namely an abnormal breast or cervical cancer screening exam from 200405 (pre reform) and again from 20072008 (post reform). We observed insurance claims for eighteen months before and after the abnormal screening exam, and then evaluated insurance coverage and frequency of health insurance switches. Aggregating number of switches at the patient level, we compared rates of insurance switches between pre and post reform periods using a Poisson regression model, adjusted for the number of months of patient care observed, age, and health center. As the Massachusetts health reform resulted in a new subsidized insurance program (CommonwealthCare), and as this was unavailable in the pre reform period, switches involving CommonwealthCare complicate pre and post reform comparisons of rates. For a clearer assessment we performed two analyses: first, where switches involving CommonwealthCare were counted as a unique change and second, where these were not counted as a unique change. Defining switches to uninsured status as an unfavorable outcome, we also compared the rates of unfavorable switches pre and post reform. RESULTS: We examined 776 women, 269 women in the pre reform period and 507 women in the post reform period. Subjects had an average age of 35 (13) years and were 60% white, 27% black, 9% Hispanic, and 3% Asian. The mean period of documented patient observation in
health center records was 23 months and included on average 14 visits. At the time of the abnormal screening exam in the pre reform period, 40% of women were uninsured, 32% had private and 28% had public insurance. In the post reform period the percent uninsured declined from 40% to 18%. In the combined pre and post reform periods, 353 (45%) had at least one switch in insurance. The adjusted annual rates of insurance switches were0.44 (95% CI=[0.39, 0.50]) in the pre reform period and 0.57 (95% CI=[0.52, 0.62]) in the post reform period when CommonwealthCare was a unique category. Under this definition, the post reform rate of switches was 29% higher than that for pre reform ($p<0.002$). When CommonwealthCare was not counted as a unique category, the adjusted annual rate of insurance switches was 0.45 (95% CI=[0.41, 0.50]) and the post reform rate of switches was 5% higher ($p=0.57$). The adjusted annual rate of unfavorable switches with pre reform=0.17 (95% CI=[0.13, 0.20]) and post reform=0.19 (95% CI=[0.16, 0.21]), indicated no significant difference. CONCLUSION: Limitations of the study include the inability to assess the length of non coverage between switches or to identify switches which occurred between health care visits. We are also unable to adjust for temporal confounding in insurance status due to the economic downturn and loss of employer based coverage. Overall our results show a major increase in the proportion of women with insurance at the time of cancer screening after insurance reform but no reduction in the instability of insurance coverage as indicated by the number of women switching to an uninsured state.

AVOIDING THE AVOIDABLE: QUALITY CARE FOR COMORBID CONDITIONS IN CANCER SURVIVORS

Claire Snyder 1; Kevin Frick 2; Robert Herbert 2; Amanda Blackford 1; Bridget Neville 3; Michael Carducci 1; Antonio Wolff 1; Craig Earle4. 1Johns Hopkins School of Medicine, Baltimore, Maryland ; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland ; 3Dana-Farber Cancer Institute, Boston, Massachusetts ; 4Institute for Clinical Evaluative Sciences, Toronto, Ontario . (Tracking ID # 10274)

BACKGROUND: Previous research has demonstrated differences in the quality of preventive care received by cancer survivors. Building on this research, we analyzed the occurrence of avoidable outcomes in cancer survivors compared to non-cancer controls.

METHODS: Using the SEER-Medicare linked database, we used 7 avoidable outcome indicators of quality care established by Asch et al. (2000) and previously implemented by Earle et al. (2004) to compare the quality of care received by cancer survivors and non-cancer controls. Cancer patients diagnosed with breast, prostate, or colorectal cancer in 2004, who were age >=66 at diagnosis, enrolled in fee-for-service Medicare during the study period, and survived at least 3 years from diagnosis were eligible. We frequency matched controls who

met the same eligibility criteria as cases, with the exception of a cancer diagnosis. The avoidable outcome indicators were evaluated during the first part of the transition to survivorship (days 3661095 from diagnosis). Logistic regression compared rates of avoidable outcomes between cases and controls, while adjusting for sociodemographic characteristics.
RESULTS: A total of 8,661 cancer cases (53% prostate, 22% breast, 26% colorectal) were matched with 17,322 controls. In analyses combining all three cancer types, no differences were found on 3/7 indicators, and cancer cases were less likely than controls to experience avoidable outcomes on 4/ 7 indicators ($p<0.05$) [see Table]. The differences were most pronounced for prostate (3/7 indicators) but less so for breast (2/7 indicators). There were no differences between colorectal cases and controls.
CONCLUSION: These data suggest that follow-up for a cancer diagnosis may be associated with improved care for comorbid conditions. Further research should investigate more specifically how survivorship care translates into improved performance on avoidable outcome quality indicators.

PHYSICIAN INCENTIVES TO IMPROVE QUALITY AND DELIVERY OF HIGH QUALITYAMBULATORY MEDICAL CARE Tara F. Bishop 1; Alex D. Federman 2; Joseph S. Ross3. 1Weill Cornell Medical College, New York, New York ; 2Mount Sinai Medical Center, New York, New York ; 3Yale University School of Medicine, New York, New York . (Tracking ID # 10281)
BACKGROUND: Financial incentives for quality and public reporting are mechanisms used to promote high quality medical care. We sought to determine the association between incentives for quality and high quality ambulatory care.
METHODS: We performed a cross-sectional study using data from the 2006 and 2007 National Ambulatory Medical Care Survey. We included ambulatory visits by adult, non-pregnant patients to generalists and internal medicine specialists practicing in non-federally funded, non-hospital-based ambulatory practices in the U.S. We examined the association between 3 physician incentives for quality (financial compensation partially based on quality, financial compensation partially based on satisfaction, and public reporting of performance measures) and 12 measures of high quality ambulatory care. The 12 measures of high quality care were categorized by patient diagnosis and visit type. We examined 4 measures during preventative care visits: smoking cessation counseling for smokers, body mass index (BMI) screening, weight reduction counseling for overweight patients, and urinalysis not performed or ordered. We examined 1 measure of high quality diabetes care: blood pressure measurement of less than 130/ 80 mmHg. We examined 2 measures of high quality heart failure care: prescription of either angiotensin converting enzyme inhibitor (ACE-I) or angiotension receptor blocker (ARB) therapy and beta-blocker therapy. We examined 2 measures of high quality coronary artery disease care: prescription of oral antiplatelet therapy and beta-blocker therapy. Finally, we examined 3 additional measures: no prescription of antibiotic therapy for upper respiratory infection, prescription of anticoagulation therapy for patients with atrial fibrillation, and 3 prescription of bronchodilator therapy for patients with COPD. For each measure, we excluded patients for which the quality measure might be contra-indicated or not applicable. We used multivariable logistic regression to assess the independent effect of physician incentives on the delivery of each of the 12 quality indicatorsRESULTS: Overall, 20.8% of visits were to physicians whose financial compensation was partially based on quality, 17.7% of visits were to physicians whose financial compensation was partially based on patient satisfaction, and 10.0% of visits were to physicians who publicly reported performance measures. Quality of ambulatory care varied: weight reduction counseling occurred in 12.0% of preventative care visits by obese patients whereas urinalysis was not performed in 93.0% of preventative care visits. In multivariable analyses, there were no statistically significant associations between financial incentives

for quality and delivery of high quality care for any of the 12 measures, nor for 11 of the 12 measures when examining the association with financial incentives for satisfaction; the exception was an association with BMI screening in preventative visits (Adjusted Odds Ratio (aOR)=2.45, 95% confidence interval [CI] 1.3-4.6, p=0.005). There was also no statistically significant association between public reporting of performance measures and delivery of high quality care for 11 of 12 measures; the exception was weight reduction counseling for overweight patients (aOR=2.05, 95% CI1.2-4-3.4, p=0.007).
CONCLUSION: We found no consistent association between incentives for quality and 12 measures of high quality ambulatory care. Our finding that on a national level financial incentives and public reporting were not associated underscores concerns about the potential impact of current quality incentive programs for improving health care quality in the U.S.

COMPARATIVE EFFECTIVENESS AND SAFETY OF MEDICATIONS FOR TYPE 2 DIABETES: AN UPDATED SYSTEMATIC REVIEW INCLUDING NEW DRUGS AND TWO-DRUG COMBINATIONS Wendy L Bennett1; Nisa Maruthur 1; Sonal Singh 1; Jodi B Segal 1; Lisa Wilson 1; Ranee Chatterjee 1; Spyridon Marinopoulos 1; Milo Puhan 1; Padmini Ranasinghe 1; Lauren Block 1; Wanda Nicholson 2; Susan Hutfless 1; Eric B Bass 1; Shari Bolen3. 1Johns Hopkins University, Baltimore, Maryland ;
2University of North Carolina, Chapel Hill, North Carolina ; 3MetroHealth Medical Center/Case Western Reserve University, Cleveland, Ohio . (Tracking ID # 10285)
BACKGROUND: Given the increase in medications for type 2 diabetes, clinicians and patients need information about their effectiveness and safety to make informed choices. We conducted an update and expansion of a systematic review to include new medication classes and 2-drug combinations.
METHODS: We searched the MEDLINE, EMBASE, and Cochrane Central Register of Controlled Trials databases from inception through April 2010 for original English-language articles and sought unpublished data from the FDA and others. Our search strategy combined terms for type 2 diabetes and medications. We selected studies in adults with type 2 diabetes that assessed intermediate outcomes (hemoglobin A1c (HbA1c), lipids, weight), long-term clinical outcomes (e.g., cardiovascular disease) and harms (e.g., hypoglycemia) in head-to-head comparisons. We included FDA-approved diabetes medications (metformin, 2nd-generation sulfonylureas, thiazolidinediones, meglitinides, DPP-4 inhibitors and GLP-1 agonists) used as monotherapy or in 2-drug combinations with either metformin or a thiazolidinedione, as well as insulin in combination with oral medications. Two reviewers serially extracted data from each article using standardized protocols. We conducted random-effects meta-analyses when there were at least 3 trials sufficiently homogenous.

RESULTS: 140 RCTs and 26 observational studies from 166 articles were included. Evidence was graded as low or insufficient for long-term clinical outcomes of all-cause mortality, cardiovascular disease, nephropathy and neuropathy. Metformin alone relative to the combination with rosiglitazone, was associated with a lower risk of fatal myocardial infarction (pooled RR 0.50, 95% CI 0.1-3.0), but event rates were low (3 cases), with imprecise estimates. Most medications lowered HbA1c by about 1%, but metformin was more efficacious than the DPP-4 inhibitors by about 0.4%. Combinations of metformin, sulfonylureas, and thiazolidinediones had similar efficacies in lowering HbA1c. Metformin decreased weight relative to thiazolidinediones (mean difference 2.6 kg) or sulfonylureas (mean difference 2.7 kg). Metformin lowered LDL relative to pioglitazone, sulfonylureas, and DPP-4 inhibitors by about 14, 10 and 5 mg/dL, respectively. Pioglitazone increased HDL more than rosiglitazone, metformin, or sulfonylureas. A higher risk of mild to moderate hypoglycemia was seen with sulfonylureas compared with metformin alone (RR 2.6, 95% CI 1.3-5.4), metformin plus a premixed insulin compared with metformin plus basal insulin and combination of metformin plus a sulfonlyurea compared with metformin plus a thiazolidinediones (RR of 6.4, 95% CI 3.3-12.5). Thiazolidinediones were associated with a non-significant increased risk of congestive heart failure relative to sulfonylureas (pooled 1.6, 95% CI1.0-2.8), and bone fractures relative to metformin. Diarrhea occurred more often for metformin compared with thiazolidinedione users and risk of lactic acidosis was not increased for metformin compared with sulfonylurea users.
CONCLUSION: Comparisons of 2-drug combinations showed little to no difference in HbA1c reduction, but some combinations increased risk for adverse events, like hypoglycemia with sulfonylureas and weight gain with thiazolidinediones. DPP-4 inhibitors improved HbA1c to a lesser extent than metformin, but when added to metformin, improved HbA1c without additional hypoglycemia. Long-term benefit and harms of diabetes medications are unclear. Results of our meta-analyses can be used to give patients more specific estimates of the comparative effectiveness and safety of the drug choices.

EFFECTIVENESS OF A PRIMARY CARE PHYSICAL ACTIVITY INTERVENTION FOR OBESE, MIDDLE-AGED WOMEN: 12-WEEK RESULTS FROM THE HEALTHY BODIES, HEALTHY HEARTS STUDY

Molly B Conroy 1; Kathleen Sward 1; Kathleen Spadaro 2; Bobby L Jones 1; Shenay Jeffrey 1; Andrea M Kriska 1; Wishwa N Kapoor1. 1University of Pittsburgh, Pittsburgh, Pennsylvania; 2Chatham University, Pittsburgh, Pennsylvania. (Tracking ID # 10289)

BACKGROUND: Physical inactivity is a significant risk factor for cardiovascular disease and remains highly prevalent in women, especially in middle-age and beyond. Healthy Bodies, Healthy Hearts (HBHH) is a randomized, controlled physical activity (PA) intervention delivered in coordination with primary care and intended to increase leisure physical activity levels and decrease weight and waist circumference (WC) in obese, inactive middle-aged women.
METHODS: We recruited 99 inactive women aged 4565 with BMI greater than or equal to 30 from 3 primary care clinics and randomized them to a 12-week, in-person activity intervention program (IP) or to an education-only, at-home(AH) group. Weekly IP sessions were 30 minute discussions followed by 30 minutes of moderate group PA; AH group received a 12-week self-guided manual based on the American Heart Associations Choose to Move program. Assessments were conducted at baseline and 12 weeks. Leisure physical activity levels were measured with the one-month version of the Modifiable Activity Questionnaire. Weight and waist circumference were measured by a trained research assistant following a standardized protocol. Differences in measures by group between baseline and 12 weeks months were analyzed with a t-test or rank-sum test using an intention-to-treat principle. Missing data was imputed with the last observation carried forward method. RESULTS: Data from 98 women was available for analysis. At baseline, mean (SD) age was 53.9 (5.4) years and 37% were black. Mean weight was 92.3 (17.7) kg, mean BMI was 34.7 (5.9), and mean WC was 105.7(11.4) cm. Median leisure PA level was 2.8 MET-hr/week (IQR 12.0). 68 (69%) women attended 12-week follow-up visit, with black women and women in AH group being more likely to be lost to follow-up. At 12 weeks, women in the IP group

had significantly greater increases in PA levels (6.3 vs. 0 MET-hr/week; p=0.001) than those in AH group. Women in IP group had modest decreases in weight (1.5 vs. -0.9 kg; p=0.19) and waist circumference (2.2 vs. -1.2 cm; p=0.15) that were not significantly different when compared to those in the AH group. CONCLUSION: The HBHH intervention was successful in increasing the physical activity levels of obese, inactive middle-aged women. However, no significant changes in weight or waist circumference were observed. It remains to be seen whether the increases in PA will be sustained in longer-term follow-up and whether the HBHH intervention could be replicated in other primary care settings.

CHRONIC DISEASE AND THE MEDICAID EXPANSION UNDER HEALTH REFORM: UNMET MEDICAL NEEDS AMONG UNINSURED ADULTS Benjamin Sommers 1; Katherine Swartz 1; Arnold Epstein1. 1Harvard School of Public Health, Boston, Massachusetts. (Tracking ID # 10297)

BACKGROUND: The Patient Protection and Affordable Care Act expands Medicaid eligibility as of 2014 to all adults with incomes up to 133% of the federal poverty level, with the promise of increasing access to care for millions of uninsured individuals. Appropriate policy planning in the areas of provider workforce and budgeting will be critical. Such planning requires estimates of the chronic disease burden and need for increased medical services among uninsured adults who will become eligible for Medicaid under health reform.

METHODS: Our analysis uses nationally-representative data from the Medical Expenditure Panel Survey (MEPS) Household Component 20042008. Our sample contains all adults aged 1964 without any health insurance, who have family incomes below 133% of the poverty level, meaning that they will be eligible for Medicaid in 2014 (n=11,279). We linked household data on income, demographics, and health care utilization with the MEPS Medical Conditions Files, which provide detailed information on self-reported conditions by ICD-9 code. We calculated survey-weighted means to estimate the prevalence of chronic diseases (including hypertension, diabetes, HIV, obesity, and schizophrenia, among others) in this population. We then compared each individuals health care utilization with national guidelines for needed therapeutic services and monitoring (e.g. at least two visits a year for hypertensive patients to monitor blood pressure according to JNC-7), and calculated the number of adults who received suboptimal care. Then we constructed a measure called a visit deficit to estimate how many additional outpatient encounters each year would be needed to provide guideline-consistent medical care (assuming multiple conditions could be addressed at the same visit), and how many additional health care providers would be needed to provide this care. RESULTS: Among uninsured adults who will be eligible for Medicaid under health reform, 51.5% reported at least one chronic medical condition, and 22.5% reported two or more. The most common conditions were obesity (27.3%), hypertension (17.6%), dyslipidemia(11.3%), depression (9.5%), asthma (9.3%), and diabetes (5.5%). 61.3% of adults with chronic conditions had received suboptimal care in the previous 12 months, with an average visit deficit of 1.16 visits per person. This translates into an additional 7.8 million visits nationally per year to provide appropriate monitoring and follow-up, corresponding to roughly 3500 additional health care providers who will be necessary in order to care for the chronic conditions among these adults.

CONCLUSION: Chronic disease is common among uninsured adults who will be eligible for Medicaid under health reform beginning in 2014. Though some of these eligible adults may not end up enrolling in Medicaid, overall our analysis probably underestimates the actual chronic disease burden given that we are using self-reported health measures and many of these conditions are likely still undiagnosed in this population. The majority of adults in our sample did not receive even the minimally recommended care for their chronic conditions. Effective outreach, appropriate case management, and significant increases in the number of Medicaid providers will be necessary to ensure that health reform leads to higher quality care for low-income adults with chronic disease.

SYSTEMATIC REVIEW OF CLINICAL PRACTICE GUIDELINES ON THE PHARMACOLOGIC TREATMENT OF TYPE 2 DIABETES MELLITUS: ARE GUIDELINES EVIDENCE-BASED? Wendy L Bennett

1; Olaide Odelola 1; Lisa Wilson 1; Shari Bolen 2; Eric B Bass 1; Deepan Dalal 1; Milo Puhan1. 1Johns Hopkins University, Baltimore, Maryland;
2MetroHealth Medical Center/Case Western Reserve University, Cleveland, Ohio. (Tracking ID # 10299)
BACKGROUND: With eleven classes of glucose-lowering medications available for the treatment of type 2 diabetes, clinical practice guidelines help inform treatment decisions. We conducted a systematic review of clinical practice guidelines addressing glucose-lowering pharmacologic therapies for type 2 diabetes to assess the quality of methods and whether they incorporate available evidence.
METHODS: We searched 2 general electronic databases (MEDLINE and Cumulative Index to Nursing &Allied Health Literature), 3 guideline-specific databases from the U.S., Canada and United Kingdom, and hand-searched the websites of 15 professional and guideline development organizations from July 2007 to March 2010. We chose this time frame because the field of diabetes is rapidly evolving and in July 2007, the Agency for Healthcare Research and Quality published a large comparative effectiveness systematic review on diabetes medications. Titles and abstracts were assessed by 2 independent reviewers, and data abstracted sequentially by 2 reviewers. Using the 2007 review, we developed a list of 7 evidence-based conclusions and then assessed whether the guidelines addressed and endorsed these conclusions. We also assessed the basis for their recommendations. Two independent reviewers rated guideline quality using the Rigor of Development (Rigor) and Editorial Independence (Independence) domains from the Appraisal of Guidelines for Research and Evaluation (AGREE) instrument. The kappa score for agreement on quality items was 0.60. RESULTS: Of the 609 titles identified, 12 guidelines, including 3 updates, contained in 20 different publications, met our inclusion criteria. Six guidelines were peer reviewed and the majority used a combination of expert opinion and literature review, including use of published systematic reviews to make recommendations. Eight guidelines agreed with the conclusion from the 2007 review that metformin is favored as first line agent. However, the two guidelines from the Joslin Clinic did not favor any one drug over another. Ten guidelines endorsed the conclusion that thiazolidinediones are associated with higher rates of edema and congestive heart failure. Two guidelines did not address any of the 7 evidence-based conclusions, and 3 guidelines endorsed all seven conclusions. In the Rigor domain, two guidelines received the highest score (4 on a scale of 14) for the item, systematic methods used to search for evidence and three for the item, clearly described methods for formulating recommendations. The range in the Rigor domain summary scores (0%=lowest to 100%=highest) was 14-100%. The National Institute for Health and Clinical Excellence guideline was the only guideline to receive the maximum score. In the Independence domain, 5 guidelines received the highest score for the item, conflicts of interest ofmembers have been recorded. The range in this domains summary scores was 8-100%. The Canadian Diabetes Association was the only guideline to receive the maximum score.

CONCLUSION: Clinical practice guidelines on pharmacologic treatment of type 2 diabetes were generally consistent with available evidence. Few guidelines used rigorous guideline development methods, including systematic searches forevidence,peer review prior to publication, and recording of conflicts of interest by group members. Professional organizations need to advocate for more consistent standards to improve guideline quality.
DECLINES IN PHYSICIAN ACCEPTANCE OF MEDICARE AND PRIVATE COVERAGE Tara F. Bishop 1; Alex Federman 2; Salomeh Keyhani2. 1Weill Cornell Medical College, New York, New York; 2Mount Sinai Medical Center, New York, New York. (Tracking ID # 10315)
BACKGROUND: A number of anecdotal reports assert that physicians are accepting fewer Medicare patients. Using data from a national survey of physicians we examined trends in physician acceptance of new patients with different types of insurance.

METHODS: Using data from the National Ambulatory Medical Care Survey (NAMCS) we examined trends in physician acceptance of new patients by insurance type from 2005 to 2008. The NAMCS is a nationally representative survey administered by the Centers for Disease Controls National Center for Health Statistics (NCHS). It contains information about physicians practicing in non-federally-funded, non-hospital-based offices throughout the United States. The fields of anesthesiology, radiology, and pathology are excluded. Our sample included all physicians who accepted new patients. We excluded obstetricians and pediatricians from our analysis of Medicare acceptance. The outcome variable was percentage of physicians who accepted new patients with Medicare, Medicaid, private capitated insurance, and private non-capitated insurance. We used multivariable linear regression to look at trends in physician acceptance of new patients by insurance type while controlling for physician and practice characteristics. We also examined acceptance of insurance stratifying physicians by specialty and practice type.
RESULTS: During the study period, there was a decline in the percentage of solo practices from 39.5% in 2005 to 32.1% in 2008 (p=0.007 for trend across years). Similarly, the number of practice owners declined over the time period (73.5 % in 2005 vs. 67.4% in 2008, p=0.006 for trend across years). There were no other significant changes in practice characteristics over the study period. Almost 95 % of ambulatory care physicians accepted new patients in 2005. This ratio did not change between 2005 and 2008. Among physicians who accept new patients, there was a small but significant decline in acceptance of new Medicare patients (95.5% in 2005 to 92.9% in 2008, p=0.01 for trend across years). In analyses stratified by physician characteristics, this decline remained significant for physicians in private practice(95.5% in 2005 vs. 93.0% in 2008, p=0.01). There was a larger decline in acceptance of privately insured non-capitated patients (93.3% in 2005 vs. 87.8 % in 2008, p between 2005 and 2008. In stratified analyses, this decline in acceptance of privately insured patients remained significant for primary care physicians (97.3% in 2005 vs. 89.9% in 2008, pRates of acceptance of new Medicaid and private capitated patients were lower overall but also showed a decline over the study period.
CONCLUSION: While reports in the literature and press highlight physicians dissatisfaction with Medicare, we found only a small decline in physician acceptance of Medicare patients between 2005 and 2008. In contrast, the decline in physician acceptance of non-capitated privately insured patients was more pronounced. These findings suggest that even patients who have health care coverage may have difficulty accessing care. . It is likely that improvements in reimbursement and expansion of primary care capacity will be needed to reverse these trends.
PHYSICIAN PERSPECTIVES ON THE ROLE OF MENTAL ILLNESS IN THE CARE OF COMPLEX PATIENTS - IT MAKES EVERYTHING MORE DIFFICULT! Danielle F Loeb 1; Elizabeth A. Bayliss 2; Carey Candrian 3; Ingrid Binswanger4. 1University of Colorado Denver, Denver, Colorado ; 2Kaiser Permanente, Institute for Health Research, Denver, Colorado ; 3University of Colorado Boulder, Boulder, Colorado ; 4University of Colorado Denver, Aurora, Colorado . (Tracking ID # 10332)
BACKGROUND: Patient complexity is often defined by the presence of multiple chronic conditions. Mental illness, specifically, has not been emphasized in current definitions of complexity used in research and policy initiatives. Although mental illness is known to have negative effects on comorbid medical illness such as diabetes or heart disease, the contribution of mental illness to patient complexity has not been examined closely. Since primary care physicians are largely responsible for the care of complex patients, we sought to explore the perceptions of internal medicine primary care physicians regarding the role of mental illness in patient complexity.
METHODS: This qualitative study utilized open-ended in-depth interviews that explored physician perceptions of patient complexity in their clinical practices and the significance of mental illness in the care of complex patients. We recruited 15 physicians from 2 university clinics and 3 community health clinics using email notices sent to all physicians in the practices. We then sampled physicians to achieve an even distribution with respect to gender, years in practice, and practice site. Physicians brought de-identified notes from 3 patients they

considered complex and were asked to refer to these notes in the interview. Interview transcripts were coded and analyzed utilizing a team-based general inductive approach. RESULTS: Emerging themes included: 1) mental illness plays a major role in patient complexity; 2) poorly controlled mental illness greatly impacts treatment of medical illness; 3) physicians perceive inadequate resources for the diagnosis and treatment of serious mental illness; and4) physicians expressed a feeling of being overwhelmed in providing care for patients with active mental illness. Physician quotations that illustrate themes are described in Table 1.
CONCLUSION: General internists perceived that mental illness contributes significantly to patient complexity. Current definitions of complexity may not adequately account for the role of mental illness in patient complexity. This study was limited by its small sample size, but these results nonetheless suggest the need to re-evaluate the role of mental illness in definitions of complexity that are employed in clinical, research and policy initiatives.

PATIENT AGE, COMORBID BURDEN, AND THE USEFULNESS OF HEART FAILURE GUIDELINES Michael Steinman 1; Carolyn Peterson 1; John Harlow1. 1San Francisco VA Medical Center, San Francisco, California. (Tracking ID # 10334)
BACKGROUND: Clinical practice guidelines have been criticized for paying insufficient attention to the unique needs of patients with advanced age and multiple comorbid conditions. However, little is known about how clinicians perceive the usefulness of practice guidelines across different types of patients.
METHODS: We conducted telephone interviews with staff physicians and nurse practitioners at 4 VA medical centers (1 per US census region) as part of a larger study evaluating physician reasons for not prescribing guideline-recommended medications to patients with heart failure. Respondents were asked to rate the usefulness of national heart failure guidelines for different types of patients on a five-point scale, with anchors of 1 (not useful) to 5 (extremely useful). We then asked respondents to elaborate on their responses in an open-ended format. Using a grounded theory approach, a random subset of 20 transcripts was reviewed to develop a taxonomy of major themes; each interview was subsequently coded for these themes.
RESULTS: Among 139 clinicians contacted, 68 (49%) completed the interview. Half (50%) were men, 80% were general internists or family practitioners, and respondents had a mean of 20 (+/10) years since professional school graduation. On a 5-point scale assessing the usefulness of practice guidelines for heart failure, the mean response was 4.4 (+/0.7) for patients age 65 years with few comorbidities, 4.2 (+/0.8) for patients age 65 years with multiple comorbidities, 3.9 (+/1.0) for patients age 80 with few comorbidities, and 3.5 (+/1.2) for patients age 80 years with multiple comorbidities (P<.001). The difference in perceived usefulness varied more by patient age than by the degree of comorbid burden (mean difference 0.6 in younger vs. older patients, vs. 0.3 in subjects with few vs. many comorbidities, P=.04). Analysis of a random selection of 20 interviews revealed 4 themes underlying the perceived utility of guidelines across different patient types: (a) patients clinic and pharmacologic complexity; (b) life expectancy and expected benefit; (c) patient preferences and adherence; and (d) the evidence basis of guidelines. Among 12 interviewees who gave different ratings for the 4 patient types, 11 cited reasons related to complexity, 5 cited reasons related to life expectancy and benefit, 2 cited preferences and adherence, and 1 cited evidence. In contrast, among 8 interviewees who gave the same rating for all patient types, 6 cited reasons related to evidence, and none cited the 3 other themes.
CONCLUSION: Clinicians perceive heart failure guidelines to be substantially less useful for patients with older age and greater comorbid burden. Concerns about the clinical and pharmacologic complexity of these patients and the expected benefits of drug therapy were commonly invoked as reasons for this skepticism.
Table: 1
Physician's Illustrative Quotes on theRole of Mental Illness in Patient Complexity Theme Illustrative Quote
Mental illness plays a major role in patient complexity
"It [mental illness] makes everything more difficult...All things are magnified...All things..." (participant # 11) "And so when someone has a severe mental health problem, even if they have pneumonia or an infection, or heart

failure or something else, if we don't deal with that mental health problem, then that is going to make treating even an acute problem very difficult ..." (participant # 7)
Poorly controlled mental illness greatly impacts treatment of medical illness
"But I think mental illness...is very interwoven into how patients kind of adopt the sick role ...because their ability to really...take the reins of their illness can be curtailed by their mental issues... patients like that, when they develop a chronic disease - even something like obesity, their ability to kind of say I'm going to really kick this and I'm going to start exercising. I'm going to change my diet. Sometimes the activation energy to embark on that is so high for them...." (participant #13)
"[E]ven if I had 70 minutes on that one patient ... who has the paranoid problem, I still wouldn't know what's going on...Every appointment I send these urgent referrals to psychiatry. 'Please see this patient. Help me. Tell me what's going on. Cause I just don't know...' " (participant # 5)
Physicians "And...it made me realize that expresseda feeling ofbeingoverwhelmed inproviding carefor patients withactive mentalillness
all of her other complaints probably were actually due to her schizophrenia...and the reason she hadn't taken her blood pressure medication, the reason she hadn't followed up with her specialist is all actually because she had untreated schizophrenia for about 10 years. So that was a little scary." (participant # 6)
Inadequate resources for the diagnosis and treatment of serious mental illness

THERES MORE TO THIS PAIN THAN JUST PAIN: HOW PATIENTS UNDERSTAND THE MANAGEMENT OF CHRONIC PAIN Marianne S Matthias 1; Edward J Miech 1; Elizabeth Sternke 1; Laura J Myers 1; Christy Sargent 1; Matthew J Bair2. 1Roudebush VA Medical Center, Indianapolis, Indiana; 2Roudebush VA Medical Center, Carmel, Indiana. (Tracking ID # 10338)
BACKGROUND: Pain is among the most commonly reported symptoms in primary care, with over half of adults suffering from chronic or recurrent pain. In this study we sought to elicit primary care patients experiences with a stepped-care intervention for chronic musculoskeletal pain.
METHODS: We conducted in-depth qualitative interviews with veterans who participated in the intervention arm of a randomized controlled trial for chronic pain management at a VA Medical Center. The stepped-care intervention consisted of analgesic treatment coupled with pain self-management strategies in step 1, followed by 6-sessions of cognitive behavioral therapy (CBT) in Step 2. A nurse care manager delivered all aspects of the intervention via telephone. For this study, patients were asked open-ended questions about the intervention and their experiences during the trial. Interviews were audio-taped, transcribed, and checked for accuracy. Sampling continued until theoretical saturation was reached. We used emergent thematic analysis to understand and interpret the data. The analytic team met weekly to identify and discuss salient themes. Discrepancies were resolved by consensus. RESULTS: Patients (N=17) were 24 to 58 years old; two were women, and all had moderate to severe chronic musculoskeletal pain. Through participation in the intervention, particularly CBT, patients described a process of figuring out their pain. Patients reported developing a greater awareness of factors that alleviate or exacerbate their pain, and the relationship between their psychological state and pain. As an example of the latter, one participant commented that he learned to recognize Okay, Im in pain. How do I feel? Am I stressed? Am I anxious? Am I down about something? Am I feeling good?I think theres probably a relevant relationship between the way we feel and our pain. Through controlling your feelings and your thought process, you could probably have an influence on your pain level. Another patient noted, Theres more to this pain than just pain. Theres the mental part of it, the part that makes you depressed, cause when youre depressed its like you have pain inside and out. Patients also described learning that successful pain management takes time. One patient explained how CBT helped him to understand the longitudinal nature

of pain management: I didnt think I was showing improvement butI just was in too much of a hurryI wanted things right now and I didnt realize it was gonna take time. So that is where I had somebody that refocused me back on what I needed to work on.
CONCLUSION: This study illustrates that how patients understand and think about pain can have an important influence on their experience of pain. By increasing patient awareness of situational and psychological triggers of pain, and understanding that controlling chronic pain is oftentimes a gradual process, patients may be better positioned to cope with and self-manage their pain.
PHYSICIAN UTILIZATION OF SMOKING CESSATION TREATMENTS IN A PRIMARY CARE SETTING Gloria Sung 1; Michael Steinberg2.
1UMDNJ-Robert Wood Johnson Medical School, Franklin Park, New Jersey; 2UMDNJ-Robert Wood Johnson Medical School, New Brunswick, New Jersey . (Tracking ID # 10339)
BACKGROUND: Even brief interventions by physicians increase patients smoking cessation, but physician treatment remains sub-
optimal. Electronic medical records (EMRs) have the potential to increase physician adherence to health guidelines and could improve tobacco dependence treatment.
METHODS: A cross-sectional EMR chart review was conducted at a University internal medicine practice from January 2001 to June 2009. Data were collected regarding gender, age, tobacco consumption, comorbidities, office counseling, referral to tobacco programs, and prescription of pharmacotherapies.
RESULTS: 277 patient charts were evaluated, with slightly more women (53%) and ages ranging from 20 to 93 (mean 52). Patients smoked a mean of 15 cigarettes per day for 27 years. In terms of treatment delivered, 89% of smokers received counseling in the office, 41% were referred to cessation services, 11% received nicotine replacement therapies (NRT), and 12% received non-nicotine cessation medications. Women had a higher trend to be referred to cessation programs than men (46% vs. 35%; p=0.06). Smokers age 5164 were referred more (56%) while those 35 or younger (28%) and 65 and older (32%) were referred less (p Smokers of 20 or more cigarettes per day were more likely than those who smoked less than 10 cigarettes per day to be referred to cessation programs (51% vs. 28%; p Smokers with anxiety disorders were more likely to receive NRT than those without anxiety (20% vs. 9%; p=0.04) and were more likely to be referred to a cessation program (55% vs. 38%; p=0.05). Smokers with hypertension were prescribed NRT non-statistically less often (6.5%) than smokers without hypertension (13%) (p=0.095).
CONCLUSION: While physicians in this setting had fairly high rates of counseling and referral, treatment was lower among younger and older smokers, smokers of fewer cigarettes per day, and those without comorbid psychiatric conditions. Having an EMR system may have facilitated documentation of patient smoking status and provision of counseling and referral. Primary care providers should continue to be encouraged to utilize proven tobacco treatment resources in all groups of smokers.
PREDICTORS OF WEIGHT LOSS SUCCESS IN PRIMARY CARE: AN EVALUATION OF THE FRESH START PROGRAM Sharon J Herring 1;
Adrienne Freidl 1; Stephanie L Ward 2; Gary D Foster1. 1Temple University School of Medicine, Philadelphia, Pennsylvania; 2Bravo Health, Philadelphia, Pennsylvania. (Tracking ID # 10341)
BACKGROUND: Despite data suggesting that modest weight loss, between 5-10% of body weight, can prevent or delay the onset of diabetes and hypertension, few primary care practices have the resources to adequately manage obesity. To serve the needs of our obese, primary care patients, we developed a weight loss-focused practice as an extension of our primary care services in 2009. We evaluated predictors of 3-month weight loss success, defined as at least 5% weight loss.
METHODS: The generalist-led Fresh Start program used a combination of behavioral skills training and goal setting along with pharmacotherapy to promote patient weight loss. At their initial visit, obese patients were asked to choose 23 obesogenic behavior change goals that were concrete and easily self-monitored, such as

Walk 10,000 steps every day, Avoid sugar-sweetened beverages, and Eat breakfast every day. Every 24 weeks thereafter, patients returned for monitoring of goal adherence and weight change. The addition of FDA-approved weight loss drugs and calorie counting were based on physician clinical judgment and patient preference. 104 patients were seen at our practice in urban Philadelphia and eligible for 3-month follow-up between July 1, 2009 and July 31, 2010. We reviewed sociodemographic and weight data from 51 (49%)

patients who returned for 3-month follow-up; the remaining 53 (51%) patients were lost to follow-up and therefore not included in this analysis. Using chi-square tests and multivariable logistic regression, we identified patient characteristics that were associated with a 3-month weight loss of at least 5%.
RESULTS: The majority of patients were female (82%), privately insured (73%), non-smokers (90%), non-depressed (63%), and previously participated in a weight loss program (88%). Mean age was 50.1 (SD 12.6) years and baseline BMI 41.4 kg/m2 (SD 8.5). 25% (n=13) lost at least 5% of initial body weight. Compared with those who did not achieve weight loss success at 3 months, successful losers had fewer previous weight loss attempts (1.4 vs.2.3, p=0.07), came to more visits (3.7 vs. 3.3, p=0.27), and were less likely to be female (69% vs. 87%, p=0.15), current smokers (0% vs. 13%, p=0.17), or have had bariatric surgery (0% vs. 16%, p=0.13). We did not find differences in weight loss success by insurance type, baseline BMI, depression history, or initial behavior change goals. Multivariable analyses revealed similar results. Mean weight loss was8.4 kg (SD 3.8) among successful losers, whereas it was only 1.6 kg (SD 2.8) among those who did not achieve weight loss success at 3 months (p<0.0001).
CONCLUSION: Primary care-based weight loss programs show promise for clinically significant weight loss among participants with 3 months of follow-up. Consistent with clinical trials for weight loss, novice dieters and male patients were more likely to achieve weight loss success. Overall attrition rates at 3 months were high, however, illustrating the need for greater efforts to expand program reach.
COMORBIDITY AND OUTCOMES IN SEVERE SEPSIS Sarah Eileen Weigel Prebil 1; Annette Esper 2; Greg Martin2. 1Emory University, Atlanta, Georgia; 2Division of Pulmonary, Allergy, and Critical Care Medicine, Emory University, Atlanta, Georgia. (Tracking ID # 10342)
BACKGROUND: Sepsis is a major health concern with increasing incidence, being the 10th leading cause of death in the US and a source of racial, gender and regional health disparities. We sought to determine the impact of acute illness severity and co-morbid medical conditions (CMMCs) on outcomes in severe sepsis patients in an urban intensive care unit.
METHODS: Prospective cohort study of adult patients receiving intensive care at Grady Memorial Hospital between 2007 and 2010 who met the ACCP/SCCM definition of severe sepsis. Data collected included demographics, APACHE and SOFA scores, sources of sepsis, CMMCs and clinical outcomes during hospitalization. Univariate analyses were performed with alpha=0.05.
RESULTS: 225 patients with severe sepsis were identified, 75% of whom had septic shock. 80% were black, 18% were white, and 63% were males. The mean APACHE II and SOFA scores were 24.9 (+/7.82) and 10 (+/3.84), respectively. Blacks had higher APACHE and SOFA scores than whites (26 vs. 22, p=0.02 and 10 vs. 8, p=0.006); there were no differences by gender. The mean number of comorbid conditions was1.35 (SD+/1.15), with 76% having at least one CMMC and 37% of patients having >1 CMMC. The most common CMMCs were diabetes (31%), chronic alcohol abuse (24%), and HIV (21%). White patients had a higher rate of alcoholism and cirrhosis compared to blacks (21% vs. 39% and 17% vs. 6%, p=0.01, respectively). Females had a higher incidence of diabetes (41% vs. 23%, p=.006) and a lower incidence of alcoholism (24% vs. 29%, p=0.05) compared to males. There were no differences in the number of comorbid conditions when stratified by gender or race. The 28-day mortality for the entire cohort was 23%, with a greater mortality observed in males when compared to females (27% vs. 16%, P=0.04). There was no difference in mortality by race. The presence or number of CMMC was not associated with ICU or hospital length of stay (LOS), development of

acute lung injury, or mortality, when compared to patients without CMMC.
CONCLUSION: Although other disease states are known to be associated with co-morbid medical conditions, in our cohort of patients, the presence of comorbidity did not influence mortality, hospital or ICU LOS, or the incidence of development of respiratory organ dysfunction. Further studies are needed to evaluate other factors that may explain the disparities in sepsis-associated mortality.
PATIENT RACE, PERCEPTIONS OF RACISM IN HEALTHCARE SETTINGS, AND PHYSICIAN TRUST Leslie R. M. Hausmann 1; C.
Kent Kwoh 1; Michael J. Hannon 1; Said A. Ibrahim2. 1VA Pittsburgh Healthcare System, University of Pittsburgh, Pittsburgh, Pennsylvania ;
2Philadelphia VA Medical Center, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania . (Tracking ID # 10346)
BACKGROUND: Discrimination in health care is more often perceived by African Americans than by whites and could underlie race differences in physician trust. We examined whether perceived institutional racism alone or in combination with personal experiences of racial discrimination in healthcare settings contributes to differences in physician trust between African American (AA) and white patients.
METHODS: The sample included AA (N=127) and white (N=303) patients being treated for osteoarthritis in Veterans Affairs orthopedic clinics. We used surveys to assess perceptions of racism in the healthcare system (institutional racism), personal experiences with racial discrimination in healthcare settings (personal racism), and patient demographic and clinical characteristics. Physician trust was assessed after patients met with an orthopedic surgeon. We used linear regression to examine whether race was associated with physician trust and whether institutional racism, personal racism, or the two combined explained the association between race and trust.
RESULTS: AA patients reported lower physician trust compared to white patients (Beta=1.20, 95% CI=2.30,-0.10). In separate models, perceptions of institutional racism (Beta=0.94, 95% CI=1.71,-0.17) and personal racism (Beta=2.78, 95% CI=4.59,-0.97) each predicted lower trust and removed the association between race and trust. Additional analyses indicated that only patients who perceived both types of racism reported lower trust than those who perceived neither type of racism (Beta=3.10, 95% CI=5.07,-1.13), and that institutional and personal racism combined explained the relationship between race and trust.
CONCLUSION: In this sample, lower physician trust among AA versus white patients was explained by perceptions of institutional racism and personal experiences of racism in healthcare settings. Efforts to foster minority patients trust in physicians may need to address issues of perceived and/or actual racial discrimination in the healthcare system.
QUALITY OF CARE OR QUALITY OF REPORTING? CHALLENGES FOR CANCERTREATMENT REPORTING. Nina A Bickell 1; Jill Wellner 2; Kezhen Fei 3; Rebeca Franco 3; Ann S McAlearney4. 1Mount Sinai School of medicine, New York, New York ; 2Veterans Administration, Fairfield, Connecticut ; 3Mount Sinai School of Medicine, New York, New York ;
4Ohio State University, Columbus, Ohio . (Tracking ID # 10347)
BACKGROUND: Complete and accurate data are essential to inform quality improvement initiatives. In 2007, the American College of

Surgeons (ACoS) began to request that hospitals report adjuvant treatments delivered beyond their walls. Yet, there is little incentive for community-based physicians to supply this information to hospital registries. We undertook this study to ascertain differences in level of treatment reporting by community vs hospital-based oncology practices to the hospital tumor registry in hospital applying for ACoS accreditation.

METHODS: We compared adjuvant breast cancer treatments reported to a hospital tumor registry (TR) during 200709, the same years a research study at that academic center collected adjuvant treatment data. Radiation (RT) for women undergoing lumpectomy, chemo- &hormonal therapy (HT) for women with a stage 2 or 3 breast cancer were obtained from the tumor registry (N=550) and the research study (N=116). Community vs hospital-based status was determined from directory searches and consultation with active
members of the faculty. Bivariate comparisons were performed with chi square analyses.
RESULTS: Treatment rates from Tumor Registry vs research study were: RT post lumpectomy (BCS) 22% vs 81%; chemotherapy 18% vs 79%; &HT 1% vs 89%. The table below compares treatment rates reported from community vs hospital-based oncologists to the TR and from the research study:CONCLUSION: Our findings suggest that the quality of breast cancer care is good but the quality of reporting is poor. Reporting rates to the tumor registry are uniformly low for adjuvant treatments, especially hormonal therapies, delivered in community-based sites. As payment is increasingly tied to performance, hospitals must overcome barriers to cancer treatment measuring &reporting, particularly among community-based physicians who have little incentive to report.

FACTORS ASSOCIATED WITH EASE OF IMPLEMENTATION IN A STATEWIDE INTERVENTION Marshall Fleurant 1; Rachel Kell 2; Chelsea Jenter 3; Lynn A. Volk 4; Fang Zhang 1; David Bates 3; StevenR. Simon5.
1Harvard Pilgrim Health Care Institute, Boston, Massachusetts ;
2Massachusetts eHealth Collaborative, Waltham, Massachusetts ;
3Brigham and Womens Hospital, Boston, Massachusetts ; 4Partners HealthCare System Inc.,, Wellesley, Massachusetts ; 5VA Boston Healthcare System, Boston, Massachusetts . (Tracking ID # 10353)
BACKGROUND: The Federal government has set 2014 as a target date for widespread electronic health record (EHR) adoption and meaningful use. However many are skeptical that we can successfully achieve meaningful use by this time. Prior studies have consistently identified a set of factors correlated with higher rates of EHR adoption: larger practice size, hospital association, presence of computerized systems other than EHR, availability of financial resources, physician ownership of the practice, and younger physician age. Between 2005 and 2009 the Massachusetts e-Health Collaborative (MAeHC) installed EHRs into physicians offices throughout three communities in Massachusetts. In this study, we aimed to identify factors associated with the ease of EHR implementation.
METHODS: In 2005 (baseline) and 2009 (follow-up) we surveyed physicians (N=560) who participated in the MAeHC pilot. For this study, we limited our sample to 163 physicians who completed the survey at both time points. Our main outcome, ease of implementation, was the answer to the following question: Was the implementation process for your EHR: a.) Very Difficult, b.) Somewhat Difficult, c.) Not Difficult. We used Chi-Squared analysis or Fishers exact tests to
identify categorical predictors; T-test and/or Wilcoxon Rank Sum Test to identify continuous predictors associated with the ease of EHR implementation. We also calculated an EHR usage score and used it as a predictor in our model. The usage score was calculated as the proportional use of a specific EHR function divided by the number of available EHR functions. We included self-reported elements of organizational culture into our analysis. (See Table A.) All variables found significant at pRESULTS: The overall response rate for the baseline and follow-up surveys were 77% and 68% respectively. Most physicians reported that the EHR implementation process was very difficult (35%), or somewhat difficult (54%), while 12% indicated that it was not difficult. On bivariate testing we found that the ease of implementation was associated with mean EHR usage score (p=.05) and baseline physician ownership (p =.02). Physicians who felt that the office staff are innovative (p=.02) and physicians who indicated that their office evaluated quality improvement efforts (p=.02) were also significantly associated with perceived ease of EHR implementation in 2009. In our adjusted analysis we found that the physicians who were owners of the practice (odds ratio [OR] 0.5, 95% confidence interval [CI] 0.2-1.0) and physicians who felt the office staff were innovative (O.R 0.4, 95% CI 0.2-0.8) were significantly less

likely to view the implementation process as difficult. (See Table B) CONCLUSION: Physicians who reported that their office staff is innovative and those who had ownership of the practice were more likely to view the EHR implementation process as not difficult. Interventions to promote EHR adoption may consider targeting practices that do not perceive themselves as innovative and those without physician ownership with special attention and tailored support.

HEALTH CARE RENOUNCEMENT FOR ECONOMIC REASONS IN SWITZERLAND Hans Wolff 1; Jean-Michel Gaspoz 2; Idris Guessous3.
1University Hospitals of Geneva, and Faculty of Medicine, University of Geneva, Geneva, Switzerland, GENEVA 4, N/A ; 2University Hospitals of Geneva, and Faculty of Medicine, University of Geneva, Geneva, Switzerland, Geneva 14, N/A ; 3University Hospitals of Geneva, and Faculty of Medicine, University of Geneva, Geneva, Switzerland, Geneva, N/A . (Tracking ID # 10355)

BACKGROUND: Most societies elaborate ways to contain increasing health care expenditures. Switzerland, which ranks second in the list of the most expensive health care systems in the world, has universal health-insurance coverage, permitting access to a broad range of services. Patients are largely satisfied with the health care they receive. However, out of pocket payments and cuts in the catalogue of reimbursed services are used as cost-containment measures in Switzerland. Ensuring socioeconomic equity and responsiveness of the health care system is often considered a high priority in health policy making, as lack of access and responsiveness may cause or at least reinforce any socioeconomic gradient in health. Health care renouncement for economic reasons may worsen chronic diseases and increase the risk of complications and hospitalization. Aims of the study were to estimate the extent of health care renouncement for economic reasons in Switzerland and to identify associated factors.

METHODS: A population-based cross-sectional survey (20082009) of a representative sample in the canton of Geneva, Switzerland (Bus Sante study). Health care renouncement, income level categories, education, occupation, insurance status and cardiovascular co-morbidities were
collected using self-rated questionnaires. Because dental care was not part of the compulsory health care insurance, associations were also assessed after excluding dental care from the definition of health care renouncement.

RESULTS: Seven-hundred sixty five men and 814 women aged 35 74 years participated for this survey, corresponding to participation rates of the 20082009 population samples of 51% and 54%, respectively. 14.5% (229/1579) (95%CI 12.7-16.2) renounced health care for economic reasons. Among those who renounced health care (N=229), 74% renounced dental care, 37% physician consultation (22% specialist, 15% general practitioner), 26% health devices (e.g. glasses or hearing device), 13% medication, and 5% surgery. Income was negatively correlated with health care renouncement (r=0.18, p-value<0,0001; table 1): each decrease in income level category provided a 48% increased risk of renouncing health care for economic reasons (OR 1.48, 1.31-1.65), while it was also associated with a significantly increased burden of cardiovascular disease or risk factors (r=0.12, p<0.0001; figure 1). This association remained when dental care was excluded from the definition of health care renouncement. During the previous 12 months, 5% of the participants were not able to pay at least once their health insurance premiums.

CONCLUSION: Renouncing care for economic reasons is not uncommon in Switzerland and concerns almost one sixth of the population. More than 30% of the lowest income group renounced health care for economical reasons in the previous year. The poorest are 13 times more likely to renounce health care than the richest. Health care renouncement may worsen health status of a substantial part of the Swiss society.

Table 1 Adjusted Odds Ratio (OR) and 95% Confidence Intervals (CI) for risk of health care renouncement for economic reasons by income during the previous 12 months among a representative sample of 35 to 74 year old citizens of the canton of Geneva, Switzerland (2008-9)

*Odds ratios are adjusted for smoking, age, gender, CV comorbidity, Swiss citizenship, education, occupation, and deductible level

PREVALENCE OF LOW HDL AND ITS ASSOCIATION WITH BMI IN A NON-DIABETIC VA POPULATION Wei Gu 1; Ronna Mallios 2; Sean McFarland 3; Jian Huang4. 1UCSF Fresno education program, Fresno, California; 2UCSF, Fresno, California; 3VACCHCS, Fresno, California;
4UCSF Fresno education program, Fresno, California. (Tracking ID # 10362)

BACKGROUND: Low HDL value is an independent predictor of cardiovascular disease (CVD). Recent evidence suggests the association between CVD and elevated triglycerides (TG). However, the contribution from low HDL with co-existing high TG is not well studied. We determined the prevalence of low HDL (less than 40 mg/dl) with normal and elevated TG (less than versus more than or equal 150 mg/dl) in a VA population, its association with BMI and other lipid components, including total cholesterol (TC) and LDLMETHODS: A retrospective chart review was conducted on 10107 non-diabetic patients at VACCHCS. Patients were divided into three groups:1) normal HDL (more than or equal 40 mg/dl) and normal TG. 2) isolated low HDL with normal TG; 3) low HDL with elevated TG. Comparisons of the mean BMI, lipid components and the TC/HDL and TG/HDL ratios were analyzed by ANOVAs. T-test of lipid parameters was performed between those with and without anti-lipid agents.

RESULTS: Mean values were: age 54.7; BMI 28.9; TC 186.8; LDL 108.2; HDL 42.4; TG 133.5; 98% males; 38% on anti-lipid medications. BMI, lipid components and the ratios of TC/HDL and TG/HDL among three groups are shown in the table. Anti-lipid agents did not affect the lipid analysis.

CONCLUSION: There was more isolated low HDL than low HDL with high TG in our non-diabetic population. Increasing BMI was significantly associated with both low HDL groups. Compared to normal group, the ratios of TC/HDL and TG/HDL were significantly higher in patients with low HDL, especially those with low HDL and high TG. TC values were significantly different in normal HDL and low HDL groups, but did not correspond well to TG values. We may need to include TG value when studying the impact of low HDL on CVD. Prospective studies in an age and gender diverse population are warranted.

PROSPECTIVE COMPARISON OF SCORES AND CLINICAL JUDGMENT TO PREDICT MAJOR BLEEDING IN PATIENTS RECEIVING ORAL ANTICOAGULANTS Jacques Donze 1; Nicolas Rodondi 2; Pierre Monney 3; Gerard Waeber 3; Jacques Cornuz 2; Drahomir Aujesky4.
1Brigham and Womens Hospital, Boston, Massachusetts ; 2Department of ambulatory and community care, Lausanne, N/A ; 3University of Lausanne, Lausanne, N/A ; 4University of Bern, Bern, N/A . (Tracking ID # 10370)

BACKGROUND: The benefit of oral anticoagulant therapy in preventing thromboembolism must be weighed against the risk of bleeding. Clinicians often use subjective clinical judgment to estimate a patients bleeding risk. As a decision aid, several objective clinical scores that predict the risk of bleeding in patients treated with oral anticoagulants have been developed. These include the Outpatient Bleeding Risk Index (OBRI) for unselected patients and the Shireman, HEMORR2HAGES, and HAS-BLED scores for patients with atrial fibrillation, the most common indication for oral anticoagulation. We sought to compare the performance of these 4 clinical scores and clinical judgment in predicting the risk of major bleeding in a cohort of patients receiving oral anticoagulants.

METHODS: We prospectively enrolled consecutive patients receiving oral anticoagulants at the department of medicine and ambulatory and community care of a Swiss university hospital (January 2008 to March 2009). The outcome was the first major bleeding event within 12 months of enrolment. We classified patients into three

classes of bleeding risk (low, intermediate, and high) according to each score and the treating physicians clinical judgment with regard to bleeding risk. The treating physicians had an average clinical experience of 4 years (SD 3.4). We assessed the discriminatory power to predict major bleeding by calculating the area under the receiver operating characteristic (ROC) curve of each score and clinical judgment.
RESULTS: We enrolled a total of 515 anticoagulated patients (mean age =71.2 years; female gender=36.1 %). The incidence of major bleeding was 6.8% (35/515) at 12 months. The major bleeding rates varied from3.0% to 6.2% among patients at low-risk of bleeding and from 4.5% to16.7% among patients at high-risk of bleeding using the various scoring systems and clinical judgment. The discriminative power of the 4 clinical scores and clinical judgment to predict major bleeding did not differ significantly and was generally poor, with areas under the ROC curve ranging from 0.54 to 0.58 (P=0.89; Table). In the subgroup of 314 patients with atrial fibrillation, the 12-month incidence of major bleeding was 6.4% (20/314). The discriminative power of the 4 scores and clinical judgment was similarly poor, with areas under the ROC curve from 0.51 to 0.59 (P=0.82; Table).
CONCLUSION: Our results indicate that neither clinical judgment nor clinical scores have sufficient power to discriminate between anticoagulated patients who are at high-risk of major bleeding and those who are not. New, accurate risk stratification methods with sufficient discriminative power to predict the risk of bleeding in patients under oral anticoagulants are needed.
RACIAL VARIATION WITH FACTOR V LEIDEN MUTATION Rosa M Michel Ortega 1; Amy Hughes 1; Javier Munoz 1; Adepeju Jinadu 1; Amr Hanbali 1; Philip Kuriakose1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 10375)
BACKGROUND: A mutation in the factor V gene (factor V Leiden) has been shown to be related to abnormal blood clotting. The factor V Leiden allele is present in about 5% of Caucasian individuals and even less commonly found in people of African and Asian descent, suggesting a single origin of the mutation. Despite the low prevalence of the mutation (near 1%) in African-Americans, the test is frequently performed by internists and specialists during the work-up of thrombophilia. We examined the associations between factor V Leiden mutation and venous thrombosis among African-Americans at our tertiary care center in the city of Detroit, with particular emphasis on whether a positive test resulted in a change in the patients management. METHODS: This retrospective chart review descriptive study comprised a population of 1,850 patients with venous thromboembolism (VTE) obtained by ICD code at our institution from January 2005 to January 2009.
RESULTS: Out of 1,850 patients with VTE, 104 patients comprising all ethnicities were tested for factor V Leiden mutations. Out of those 104 patients tested for factor V Leiden, 94 patients (90.3%) were negative for the mutation and 10 patients (9.6%) were positive (Table 1). Patients across all ethnicities with positive test results exhibited a heterozygous factor V Leiden mutation with no cases of homozygous mutations being seen. Most of the cases (70%) were not requested by a hematologist and were instead more commonly ordered by the internist. Of note, the immediate management of each particular patient did not change based on the results of the factor V Leiden testing (100%). We then further examined the patient population in regards to ethnic distribution. The ethnic distribution of our patient population (Algorithm 1) included 1060 African-Americans, 682 Caucasians, 30 Asians, 18 Hispanics and 12 Middle Eastern patients. Race was documented as other or not specified in 48 patients. Out of 1,060 African-Americans with VTE, 53 patients were tested for factor V Leiden gene mutation and only 3 cases (0.2%) were heterozygous for such mutation. As noted above, no homozygous factor V Leiden cases were detected irrespective of the ethnic group studied.
CONCLUSION: Ethnic stratification is important in developing cost-effective selective screening programs to identify individuals at risk for thrombophilia. There is little evidence that the identification of inherited thrombophilias, such as factor V Leiden gene mutation, dictates a change in management of duration of anticoagulant therapy for patients with VTE. This fact seems to be particularly true in the African-American population due to its very low incidence. Careful history and physical exam remain the most important tools to decide the management of patients with VTE surpassing any laboratory testing including factor V Leiden gene

mutation.

INTEGRATING PATIENT-REPORTED INFORMATION INTO AN ELECTRONIC MEDICAL RECORD TO ENSURE SAFE PRESCRIBING TO WOMEN OF CHILDBEARING POTENTIAL Sanithia Williams 1; Rachel Hess 1; Sara M Parisi 1; Steven Handler 1; Grant Shevchik 2; Wishwa Kapoor 1; Eleanor Bimla Schwarz1. 1University of Pittsburgh, Pittsburgh, Pennsylvania; 2UPMC, Pittsburgh, Pennsylvania. (Tracking ID # 10376)

BACKGROUND: Certain medications should not be used by women who are pregnant or breastfeeding. Primary care providers are charged with counseling women about the risks that may be posed by medication use, however, it is challenging for clinicians to routinely assess womens pregnancy intentions, use of contraception, and lactation status. METHODS: We developed a system that uses wirelessly-networked tablet computers to allow women to enter pregnancy, contraception and lactation information which is then automatically extracted and transferred into the patients electronic medical record prior to their visit with a primary care provider. We implemented this system at two community-based primary care practices in Western Pennsylvania. RESULTS: Over a 7-month period, 962 female patients entered pregnancy, contraception, and lactation information that was extracted from a tablet computer into their patient record prior to their visit with a provider at two community-based primary care practice in Western Pennsylvania. On average, these female patients were 35 (+/10) years
old. Introduction of this system did not significantly increase wait times at the clinics front desk. Information that

might affect prescribing decisions was entered by 360 (37%) women. Current pregnancy or an effort to conceive was reported by 40 (4%) of women, while another 33 (3%) stated they wouldnt mind becoming pregnant. Among the 856 (89%) who stated they were not trying to become pregnant, 60 (7%) were using no method of contraception while 214 (25%) were relying on relatively ineffective, behavioral or barrier methods of contraception. Thirteen women (1%) reported currently breastfeeding an infant. Notably, only 10 women (<1%) selected the prefer not to answer option when the tablet stated, Some of the medicines that your doctor may prescribe can be harmful during pregnancy. We feel it is important to understand each patients plans and risks for pregnancy. Are you currently pregnant or trying to become pregnant?
CONCLUSION: Systematic collection of patient-reported reproductive health information in the primary care setting is feasible, acceptable to women, and has the potential to reduce unsafe prescribing to women of childbearing age.

MULTISOURCE EVALUATIONS OF RESIDENTS FROM THE VIEWPOINT OF THE EVALUATORS Susan Michelle Nikels 1; Suzanne Brandenburg2. 1University of Colorado Hospital, Denver, Colorado; 2University of Colorado, Denver, Colorado. (Tracking ID # 10385)

BACKGROUND: Multisource evaluations of residents are required by the Accreditation Council for Graduate Medical Education (ACGME), but there are no previous studies indicating the best way to collect this data from a range of healthcare professionals with varying amounts of contact and diverse types of interactions with residents. The purpose of this study is to gather input from non-physician continuity clinic staff (nurses, medical assistants and administrative staff) regarding their comfort with and ability to assess various aspects of resident performance and behavior.
METHODS: Based on the input of a focus group, we prepared and distributed an anonymous survey to the non-physician staff at 6 Internal Medicine Residency Continuity Clinic sites all associated with the University of Colorado Internal Medicine Residency program. The survey was designed to gather opinions on what competencies the staff members think they are qualified to assess and have adequate opportunity to observe in the residents with whom they interact. Respondents completed a 16-question survey about their participation in resident evaluations. They were asked about their perceptions of resident evaluations using a 4-point response scale (1 = strongly disagree; 2 = disagree; 3 = agree; 4 = strongly agree). Questions addressed respondents age, degree, position, years experience, experiences providing feedback to residents and preferences regarding frequency and method of providing feedback. One item asked respondents how well they could evaluate 12 resident behaviors using a 3-point response scale (1 = not able to evaluate; 2 = somewhat able; 3 = very well). Based on an exploratory factor analysis of these behaviors (principal axis extraction with varimax rotation) we developed three scales: Professional Behavior, Medical Knowledge and Judgment, and Patient Interaction. Because the number of items differed for each scale, item means were calculated. Descriptive analyses were conducted to characterize the sample, beliefs about participation in resident evaluations and experiences providing feedback to residents. To examine whether respondents differed in their ability to evaluate the three types of resident behavior, paired t-tests comparing nurses and other clinic staff were estimated.
RESULTS: There were 61 responders to our survey consisting of nursing staff, medical assistants and administrative staff of the 6 participating internal medicine outpatient clinics. Among the responders, nurses tended to be older and have more job experience. Overall, the clinic staff agreed that it was important to formally evaluate the residents (86.9% agree or strongly agree), although the nurses tended to more strongly agree. When asked how well they could evaluate 12 resident behaviors, all staff were more likely to feel they could evaluate professional behaviors very well (62.1% respect to staff; 61% professional dress/attire; 54.2% communication skills with staff; 43.9% ability to work as part of a team). Although overall respondents were not comfortable evaluating medical knowledge and judgment (45.6% felt not at all able to assess adequacy of

medical knowledge; 41.1% not at all able to evaluate clinical judgment), nurses were more comfortable than other staff members in evaluating these competencies. Limited contact with the residents was cited by 85.7% of respondents as the biggest barrier to evaluating the residents. Lack of confidentiality was not a significant concern in the evaluation process (1.8%). Significant feedback is still given verbally rather than on formal written evaluations.
CONCLUSION: Non-physician clinic staff members agree that it is important to evaluate residents and they feel secure that evaluations are handled confidentially. Clinic staff members are most comfortable providing feedback on professional behaviors and significantly less comfortable giving feedback on medical knowledge. Nurses are more confident providing feedback on clinical judgment and medical knowledge than other staff members. How much of this is related to age and job experience is unclear. A significant amount of feedback is provided verbally to residents and/or to the attending physicians supervising the residents but not necessarily captured in a formal written evaluation process as required by the ACGME. Future work should look at ways to capture real time verbal feedback and attempt to standardize the competencies we ask our non-physician staff members to evaluate.

INFLUENCE OF DEBT AND ANTICIPATED INCOME ON MEDICAL STUDENT CAREER CHOICE IN INTERNAL MEDICINE Martha Grayson 1; Dale Newton 2; Lori Foster Thompson3. 1Albert Einstein College of Medicine, Bronx, New York ; 2Brody School of Medicine, East Carolina University, Greenville, North Carolina ; 3North Carolina State University, Raleigh, North Carolina . (Tracking ID # 10397)
BACKGROUND: Recent studies suggest that increasing debt and desire for higher incomes may be influencing medical student career choice. This study examines career decisions of students who begin medical school intending to pursue careers in Internal Medicine. The objectives were to determine how debt, the self-rated importance placed on income, and future income projections relate to intentions to pursue a subspecialty in Internal Medicine (IMSS) rather than General Internal Medicine (GIM). The anticipated salary changes were also examined for those students switching out of Internal Medicine.
METHODS: Students at New York Medical College and Brody School of Medicine at East Carolina University were surveyed annually at matriculation (M1) and just prior to graduation (M4). The data set included 17 consecutive years of M1 surveys and 16 years of M4 data. The overall response rate was 81%. The responses of students who expressed an interest in Internal Medicine at either M1 or M4 were analyzed. Additional analyses focused on the subset of students who expressed an interest in Internal Medicine at M1 and subsequently completed a follow-up survey at M4, yielding paired data that enabled the investigation of trends over time. Overall, the analyses examined the relationships among the following factors: reported debt (in dollars), anticipated income 5 years after residency (in dollars), student reported influence/ importance of income on career choice (Likert scale rating), association of self-rated importance of income with anticipated income, and stated career choice.
RESULTS: 239 M1 students expressed interest in GIM; 404 in IMSS. By graduation, these numbers changed to 277 and 343 respectively. The trends in Table 1 were identified. Longitudinal changes in anticipated income were also documented. Students aspiring to GIM at M4 expected $139 K ($14 K more than what they anticipated at M1); those aspiring to Internal Medicine subspecialties expected $179 K (up $43 K from what they anticipated at M1); those who switched out of Internal Medicine expected $207 K (up $62 K from M1).
CONCLUSION: Both debt and expected income may push medical students initially interested in General Internal Medicine towards a career in a subspecialty of medicine or to a career in another specialty outside of Internal Medicine. Changes in the payment system to more properly reimburse general internists may be needed to attract talented students whose financial concerns may otherwise discourage them from pursuing a generalist career. Since concern about debt is associated with career choice, new loan forgiveness programs linked to practice in General Internal Medicine should also be developed as a method to assist in sustaining the numbers of students choosing this career path.

A POSITIVE PHQ-2 DEPRESSION SCREEN AMONG HOSPITALIZED HEART FAILURE PATIENTS IS ASSOCIATED WITH LOWER LEVELS OF QUALITY OF LIFE AND PREDICTS ELEVATED 12-MONTH MORTALITY RISK
Bruce L. Rollman 1; Bea Herbeck Belnap 1; Fanyin He 1; Sati Mazumdar 1; Herbert C Schulberg 2; Charles F. Reynolds1.
1University of Pittsburgh, Pittsburgh, Pennsylvania; 2Weill Cornell Medical College, White Plains, New York.
(Tracking ID # 10413)
BACKGROUND: Heart failure (HF) affects over 5.7 million Americans, with over 660,000 newly diagnosed cases, 290,000 deaths, and $37 billion in treatment costs incurred yearly. One potential contributor to poor outcomes is unrecognized depression. An American Heart Association (AHA) Science Advisory has advocated routine screening of cardiovascular disease patients for depression to identify those who may require further assessment and treatment with use of the two-item Patient Health Questionnaire (PHQ-2) at a minimum (Circulation, 2008; 118:1768). Yet, the value of a positive PHQ-2 screen among HF patients is unknown.
METHODS: We administered the PHQ-2 to HF patients (ejection fraction (EF) <40%) with NYHA class II-IV symptoms prior to discharge from 4 Pittsburgh-area hospitals. We defined a positive depression screen as one or both PHQ-2 items endorsed affirmatively (In the past two weeks have you: (a) had little interest or pleasure doing things; or (b) felt down, depressed or hopeless; PHQ-2 (+)), and a negative screen as both items endorsed negatively (PHQ-2 ()). According to prespecified sample size calculations, we oversampled PHQ-2 (+) to PHQ-2 () patients. Then, at baseline, we collected sociodemographic and clinical data, and later contacted patients or their designated secondary contacts (e.g., spouse, adult child) via telephone to ascertain vital status. Later, a study physician blinded as to subjects baseline PHQ-2 status reviewed each report of death, including hospitalization records and death certificate, and assigned a cause of death. We evaluated differences between study cohorts defined by PHQ-2 status for statistical significance using t- and chi-squared tests for baseline data, and log-rank tests for 12-month incidence of all-cause and cardiovascular mortality calculated from Kaplan-Meier analyses with Cox models to adjust for baseline covariates.
RESULTS: Over a 16-month period ending 4/09, 610 HF patients consented to our screening procedure; 526 (86%) were both NYHA and PHQ-2 eligible; and 473 (90%) met all other study requirements. Compared to PHQ-2 () patients (n=101), PHQ-2 (+) patients (n=372) were younger (65 vs. 70), more likely to have NYHA III/IV symptoms (67% vs. 39%), and reported lower levels of physical (SF-12 PCS: 30.7 vs.34.3) and mental health-related quality of life (SF-12 MCS: 44.4 vs.58.5) (all p<0.002). However, they were similar on other baseline clinical and sociodemographic characteristics (e.g., 65% male, 85% White, 41% diabetic, 25% mean EF). We confirmed vital status on all 473 study patients (100%) as of 12/31/09 and identified 83 deaths, including 55
(66%) for cardiovascular causes. At 12-months follow-up, 20% of PHQ-2 (+) vs. 8% of PHQ-2 () patients had died (p=0.007), and PHQ-2 (+) status remained associated with both increased all-cause (hazard ratio (HR): 3.0 (95% CI: 1.4-6.4); p=0.004) and cardiovascular mortality (HR:2.6 (1.1-6.3); p=0.03) even after adjustment for age, gender, EF, NYHA class, diabetes, hyponatremia, ACE-I/ARB use, antidepressant use, and a variety of other baseline covariates.
CONCLUSION: Among hospitalized HF patients, a positive PHQ-2 depression screen prior to discharge home is associated with lower levels of HRQoL and elevated mortality risk at 12-month follow-up. While our findings support the AHA Science Advisory for HF patients, clinical trials remain necessary to determine whether effective depression treatment can improve health-related quality of life and reduce mortality in this medically ill population.
PATIENT AND SERVICE LEVEL ASSOCIATIONS WITH THE QUALITY OF END OF LIFE CARE AT AN

ACADEMIC MEDICAL CENTER Anne Walling 1; Karl Lorenz 2; Steven Asch 2; Neil Wenger1. 1University of California, Los Angeles, Los Angeles, California; 2VA Greater Los Angeles Healthcare System, Los Angeles, California. (Tracking ID # 10415)

BACKGROUND: Little is known about what influences the quality of end of life care. We evaluated the relationship between patient clinical and demographic characteristics and inpatient clinical service with the quality of end of life care among patients dying in the hospital. METHODS: Medical records were abstracted for 496 adult decedents hospitalized for at least 3 days between April 2005 and April 2006. Sixteen of the Assessing Care of Vulnerable Elders (ACOVE) quality indicators (QIs) that focus on end of life care (communication and symptom management) were measured and an overall patient-level quality score was calculated. Because patients triggered different QIs with varying pass rates, the observed quality score for each decedent was compared against the expected score of a hypothetical patient who had triggered the identical QI pattern to compute an observed-minus-expected score. Bivariate relationships between quality and patient characteristics (age, sex, race, ethnicity, religion, insurance status, marital status, pre-hospital venue, mental status on admission, and presence of end stage disease on admission) and clinical service were studied. Because specific end stage disease was highly correlated with clinical service (cancer and oncology service, liver disease or transplant with liver service, all rs>0.6 and ps<0.001), we evaluated the association of quality with patient characteristics and clinical service in separate regression equations. Published literature suggests that a minimally clinically significant difference in quality is approximately 510%. RESULTS: In bivariate analyses, patients with advanced cancer and patients admitted to the oncology service received significantly higher quality scores and lower quality was associated with Hispanic ethnicity, being considered for transplant, not having religion documented in the medical record, admission to the liver service, and admission to a

surgical intensive care unit. In a linear regression model that included all patient characteristics, patients who were considered for transplant during the admission received lower quality end of life care. Adjusting for all other variables, patients considered for transplant received 7% lower quality score compared to patients not considered for transplant (p=0.02). Lack of documentation of a patients religion in the medical record was associated with a 10% lower quality score compared to Christian/Protestant patients (p=0.02). In a linear regression model that included all patient services, patients cared for by a surgical intensive care unit received 9% lower quality compared to patients on a medical service (p=0.03).

CONCLUSION: This analysis identified factors associated with lower quality inpatient end of life care that can be targeted for quality improvement. Potential organ transplant recipients and patients admitted to the surgical intensive care unit at the facility studied are at particular risk for lower quality treatment at the end of life. The role of attention to religion and whether similar influences exist at other hospitals merits study.

THE ROLE MODELS OF BEDSIDE TEACHERS: A QUALITATIVE ANALYSIS Jed Gonzalo 1; Briar Leigh Duffy 2; Dario Torre 3; David Elnicki4. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts ; 2University of Pittsburgh/VA Pittsburgh, Pittsburgh, Pennsylvania ; 3University of Pittsburgh, Pittsburgh, Pennsylvania ; 4University of Pittsburgh, Wexford, Pennsylvania . (Tracking ID # 10422)

BACKGROUND: The attributes of excellent physician role models include teaching that is focused on the importance of the doctor-patient relationship, competence in the clinical setting, and spending time with learners while conducting rounds on the wards. Although bedside rounds have traditionally been integral to teaching services, their frequency has decreased, despite learner and patient preferences for this method of rounding. In a changing healthcare environment, where pressure for clinical productivity leads to reduced teaching time at the bedside, it is important to explore the opinions of experienced bedside teachers about what constitutes a quality bedside teacher. Therefore, we sought to identify characteristics perceived by bedside teachers to be associated with quality bedside teachers.

METHODS: Using purposeful sampling, we identified 11 academic institutions and a site principal investigator at each location to identify physicians who perform bedside rounds according to a pre-determined definition and actively serving as inpatient attending on teaching services. From February to November of 2010, 2 investigators conducted digitally-recorded, semi-structured, one-on-one telephone interviews, each lasting 1 hour, and consisting of open- and closed-ended questions pertaining to prior education on bedside rounds and the role models whom they identified as quality bedside teachers. Each interview was transcribed verbatim and an inductive thematic qualitative analysis was completed coding the transcripts for emerging themes. Participant comments were reviewed multiple times, coded into themes, and reduced to 5 categories. Quality control was maintained with 2 independent researchers coding the data, verifying codes, and developing the category system. The Institutional Review Boards at all institutions approved the study.
RESULTS: Ten institutions completed IRB submission and identified a minimum of 3 participants for inclusion. We completed thirty-four interviews, the majority with assistant professors (44%). The participants averaged 13.7 years of academic experience and 18 weeks on the teaching services with housestaff over the previous 2 years. Most participants did not receive formal education on bedside rounds during residency (85%), fellowship (79%), or faculty time (65%). All participants identified a physician whom they labeled as an equality bedside teacher. In response to why they were considered an equality bedside teacher, 5 thematic categories were identified: modeling of clinical actions, modeling compassionate patient-physician interactions, interactive teaching by engaging all participants, patient-centered teaching, and integration of knowledge and clinical practice.
CONCLUSION: The professional development of the bedside teachers was positively impacted by physicians who taught at the bedside, as all participants identified a quality bedside teaching role model. The characteristics of excellent role models have been shown to include spending time on rounds with housestaff and demonstrating the physician-patient relationship, both of which were reiterated in our study. In addition, the specific attributes identified in quality bedside teaching role models embody the integration of the patient and learner at the bedside. With the downward trend in bedside rounds, the opportunities to model humanistic, patient-centered learning, which are more difficult to demonstrate in the classroom, are being lost. Faculty development efforts to promote bedside skills with these patient-centered attributes may assist in developing the next generation of quality bedside teachers.
ASSESSING VARIATION IN PPI DISCONTINUATION IN VA LONG-TERM CARE Amy Linsky 1; John A. Hermos 2; Michael Shwartz 3; James L. Rudolph4. 1Boston Medical Center and Center for Organization, Leadership, and Management Research, VA Boston Healthcare System, Boston, Massachusetts ; 2Massachusetts Veterans Epidemiology Research and Information Center, VA Cooperative Studies Program, VA Boston Healthcare System, Boston, Massachusetts ; 3Center for Organization, Leadership, and Management Research, VA Boston Healthcare System, Boston, Massachusetts ; 4Geriatric Research Education and Clinical Center, VA Boston Healthcare System, Boston, Massachusetts . (Tracking ID # 10429)
BACKGROUND: Proton pump inhibitors (PPI) are commonly prescribed medications that are often initiated and continued without clear indication, contributing to overmedication. We previously determined that within Veterans Affairs (VA) long-term care facilities, patient characteristics were only weakly associated with PPI discontinuation within 180 days of admission, but we did not account for variability between facilities. Our current objective is to analyze PPI discontinuation across these VA facilities and to determine the amount of variability accounted for at the patient- and facility-levels.
METHODS: We linked national VA administrative and pharmacy data with Minimum Dataset patient assessments to identify patients admitted to VA long-term care in 2005 who were prescribed an oral PPI within seven days of admission, stayed a minimum of seven days, and were not receiving hospice care. This yielded 9,589 patients (baseline PPI users) across 115 facilities. Our primary outcome was PPI discontinuation within 180 days of admission, with an intermediate assessment at 28 days. Facility-level characteristics included

annual admissions and average daily census (size). Patient-level characteristics included age, sex, pre-admission PPI prescriptions and hospitalizations, number of medications, functional status, and comorbidities. Facility-level prevalence of baseline PPI use equaled the number of baseline PPI users relative to number of admissions. Facility-level PPI discontinuation equaled the number of discontinuations relative to the number of baseline PPI users. Descriptive statistics summarized facility-level characteristics. Separate simple linear regressions associated both baseline PPI prevalence and discontinuation with both facility admissions and size. Hierarchical linear models, which account for the clustering of patients within facilities, partitioned the variation in PPI discontinuation across patients and facilities.
RESULTS: The 115 facilities had a mean of 311 annual admissions (SD 221) and an average daily census of 104 patients (SD 64). At the facility-

level, the median proportion of baseline PPI users was 28% (IQR 21-35%). There was no statistically significant association between prevalence of baseline PPI use and facility size. At the facility-level, within 28 and 180 days of admission, the median proportions of baseline PPI users with a discontinuation were 10% (IQR 5-15%) and 34% (IQR 20-45%), respectively. In separate linear regression models, greater discontinuation was associated with more admissions (28 days, p=0.003; 180 days, p=0.002) but not with facility size (28 days, p=0.63; 180 days, p=0.81). Within 180 days, we identified that 7% of the total variance in PPI discontinuation occurred between facilities, of which 13% was due to facility size. The remaining 93% of the variance occurred within facilities, of which 5% was due to the included patient characteristics. Within 28 days, the variation in PPI discontinuation was similarly partitioned across patients and facilities.
CONCLUSION: A greater proportion of variability in PPI discontinuation was found within facilities compared to between facilities, but the patient- and facility-level characteristics we analyzed explained little of the variance in PPI discontinuation. Therefore, other factors associated with medication discontinuation need to be identified in order to better address overmedication among elderly long-term care residents.

HOSPICE CARE AND RESOURCE UTILIZATION IN MEDICARE BENEFICIARIES WITH HEART FAILURE

Saul Blecker 1; Gerard Anderson 2; Robert Herbert 2; Nae-Yuh Wang 1; Frederick Brancati1.
1Johns Hopkins University School of Medicine, Baltimore, Maryland;
2Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland. (Tracking ID # 10437)

BACKGROUND: Hospice use is increasing in the heart failure population, but its effect on both the cost and intensity of care in this population has not been well examined. We evaluated whether use of hospice care was associated with decreased expenditures and other markers of resource utilization among Medicare beneficiaries with heart failure near the end of life.
METHODS: Using a national 5% sample of Medicare claims data, we performed a cross-sectional analysis of resource utilization among beneficiaries during the last six months of life. We included all beneficiaries over the age of 65 with a heart failure diagnosis who died in 2007. The diagnosis of heart failure was established using the International Classification of Diseases, Ninth Revision (ICD-9) code 428 listed as either a hospital discharge diagnosis or in at least two physician claims in the year preceding the last six months of life. Beneficiaries were considered to have hospice enrollment if Medicare had reimbursed at least one day of hospice services during the last six months of life. Markers of resource utilization included total Medicare expenditures, number of hospitalizations, and number of intensive care unit (ICU) days. We also evaluated performance of certain procedures, including cardiac catheterization, non-invasive ventilation, and mechanical ventilations. We used negative binomial regression models to compare costs, hospitalization rates, and ICU days between hospice and non-hospice beneficiaries, adjusting for covariates, including age, gender, race, geographic location, comorbidities, and prior hospitalizations. Log-linear regression models were used to

compare utilization of procedures between hospice and non-hospice beneficiaries with adjustment for covariates.
RESULTS: Of the 16,613 beneficiaries who died with heart failure in 2007, 6,436 (38.7%) received hospice care during the last six months of life. Hospice care was more common in women, older patients, residents of the South or Midwest regions, and in patients with cancer or dementia. The mean total medical expenditures during the last six months of life were $31,793 (SD 25,691) among beneficiaries with hospice care, in comparison to $34,067 (SD 40,561) among beneficia-
ries without hospice care. However, after adjustments for covariates, hospice care was associated with 4% higher expenditures (cost ratio 1.04, 95% CI 1.01-1.07; p=0.02). The most important confounders appeared to be age, race, and geographic location. Expenditures related to hospice services accounted for 23% (mean $7,462) of total expenditures among individuals who had received hospice care. Hospice use was associated with lower rates of hospitalization (adjusted incidence rate ratio (aIRR) 0.87, 95% CI 0.84-0.89) and ICU days (aIRR 0.68, 95% CI 0.63-0.73). Hospice use was also associated with performance of fewer medical procedures, including cardiac catheterization (adjusted prevalence ratio (aPR) 0.63; 95% CI 0.52-0.75), noninvasive ventilation (aPR 0.67; 95% CI 0.57-0.79), and mechanical ventilation (aPR 0.33; 95% CI 0.29-0.37). CONCLUSION: Despite lower rates of hospitalization, ICU days, and invasive procedures, hospice care was associated with higher expenditures for heart failure patients following adjustment for covariates. Within Medicare, financial savings related to reduced intensive medical care appears to be offset by the expenditures related to hospice care itself. Hospice for heart failure patients should focus on quality of life and patient preferences; cost savings should not be expected.
MOVING INTO TEAM-BASED CARE: FIRST STEPS TOWARDS THE PATIENT-CENTERED MEDICAL HOME IN A UNIVERSITY-BASED PRACTICE Rita S. Lee 1; Kelly J. White 1; Susanne Felton 1; Amy G. Huebschmann1. 1University of Colorado, Denver, Colorado. (Tracking ID # 10442)
BACKGROUND: There is a national movement to transform primary care practices into patient-centered medical homes (PCMH). One of the 7 joint principles of the PCMH is that the personal physician leads a team of individuals at the practice level to collectively take responsibility for the ongoing care of patients. Thus, a necessary step to become a PCMH is to organize physician-led teams. Academic general internal medicine practices struggle to achieve team-based care due to a lack of dedicated funding or protected time to develop this infrastructure. We piloted a model of team-based care in a University-based general internal medicine practice. Our goals were to increase provider, staff, and patient satisfaction, and to improve patients continuity of care. METHODS: Our team-based care pilot included 9 providers (8 physicians, 1 physician assistant), 1 nurse (RN), and 2 medical assistants (MA) approximately 1/3 of the practice. We held 1-hour team meetings twice per month for the first 3 months and monthly thereafter. The team identified areas for improvement and devised strategies to achieve organized team-based care. To optimize team efficiency, we increased RN and MA duties within the scope of their practices. Ten months after initiating the team pilot, we assessed provider, staff, and patient satisfaction. All providers (n=29) and staff (n=27) were surveyed anonymously regarding overall job satisfaction, time spent on paperwork and phone calls, and collaboration with RNs, MAs, or clinic administrative staff. Telephone surveys of a random sample of 40 patients were also conductedwith half followed by providers in the team-based pilot. Survey questions addressed ease of appointment scheduling, availability of appointments, and seeing the provider of their choice. Differences between team and non-team provider, staff, and patient satisfaction were analyzed using the Cochran-Mantel-Haenszel test. Continuity of care measures were assessed as the percentage of visits with a single provider or only team providers over comparable pre-intervention and post-intervention time periods and analyzed using the Chi-Square test.
RESULTS: We found no statistically significant differences between team and non-team providers for overall job satisfaction, amount of time spent doing paperwork, time spent on phone calls, control over work environment, and collaboration with nurses or clinic administrative staff. Team-based providers reported a greater level of

satisfaction in collaborat-

ing with medical assistants as compared to non-team providers (p=0.01). There were no significant differences in any patient satisfaction measures in team vs. non-team patients. There was no significant difference in continuity of care measures pre- and post-intervention. CONCLUSION: Moving from a clinical practice that is autonomously provider-driven to provider-led team-based care is feasible in a University-based general internal medicine practice without adversely impacting patient, provider, or staff satisfaction. Using the lessons learned from the team pilot and the data gathered, we expanded the team model to the entire practice. The transition into teams has been facilitated by moving in a thoughtful, staged, and data-driven manner.

A COMMUNITY-BASED, CULTURE-CENTERED APPROACH FOR DEVELOPING EFFECTIVE HEART DISEASE PREVENTION MESSAGES FOR RACIAL/ETHNIC MINORITIES Namratha R Kandula 1; Neerja Khurana 1; David Baker 1; Sara Glass 2; Quinn Stephens 1; Manasi Tirodkar 3; Gregory Makoul4.
1Northwestern University, Chicago, Illinois ;
2Northwestern university, Chicago, Illinois ; 3NCQA, Washington, District of Columbia ; 4Saint Francis Hospital and Medical Center, Hartford, Connecticut . (Tracking ID # 10460)

BACKGROUND: Despite increasing calls for coronary heart disease (CHD) prevention efforts to target minorities, little is known about how best to target CHD prevention messages to different racial/ethnic groups. We used a community-based, culture-centered approach to develop a multimedia CHD prevention education program (PEP) targeted to South Asian (Asian Indian and Pakistani) immigrants, a group that has higher rates of CHD than other U.S. racial/ethnic groups. METHODS: The PEP included six, 5-minute video modules (brief text, narration, simple graphics, and photographs) about CHD, risk factors, and prevention. The PEP content was developed from formative qualitative and quantitative interviews with South Asians, health communication and behavior theory, and CHD prevention guidelines. Both surface structures (e.g. language, foods) and deeper structures (e.g. health beliefs, values) of South Asians socio-cultural context were integrated into the PEP. Prototype modules were shown in focus groups to English and Hindi-speaking community members recruited from a Federally Qualified Health Center and 2 South Asian community centers in Chicago. Participants commented on the content, clarity, and cultural-appropriateness of each module. Twenty focus group discussions (n=120) were conducted. Audio-taped discussions were transcribed, translated, and back-translated. In this iterative process, emergent thematic categories were organized using theoretical constructs underlying the PEP; the PEP was revised based on focus group themes, and then re-shown in focus groups. Here, we present focus group data related to the first module, What is Heart Disease? RESULTS: Participants mean age was 51 years (range 2075), and 66% were women. All were immigrants and had lived in the U.S. an average of 13 years. Sixty percent spoke English, and 66% were college graduates. To capture audience attention and increase perceived susceptibility to CHD, the initial opening statement in the first module was, Heart attack is the number one killer of Indians and Pakistanis. Most participants said this statement was too strong and direct; one participant stated, This looks like a bold attack because you are pinpointing one community. Others agreed, noting, Heart attacks happen in all communities. The opening statement has now been modified to: Heart attack is the number one killer of people around the world. Studies show that Asian Indians and Pakistanis are more likely to have heart attacks than people from other communities. Participants also said that the opening image, of an older South Asian woman, did not capture the heterogeneity among South Asians and therefore, made them feel that they were not at risk. To address this, we added a diverse montage
of South Asians to the PEP. This image was more positively received and as one participant said it conveyed, Anyone of us can have a heart attack. Finally, the prototype PEP briefly addressed the belief that stress causes CHD because this theme had been important in formative interviews; the PEP tried to emphasize that CHD is caused by clogged blood vessels, not stress. Focus group participants said this was ineffective: You are trying

to address the myth here, but since the myth is so deep rooted and strongly believed, that just one sentence will not take it away. The revised PEP explains the relationship in more detail, acknowledges the role that stress can play in CHD, and now also includes an additional seventh module on stress management and health. CONCLUSION: A community-based, culture-centered approach to developing CHD prevention messages for South Asians led to key lessons that can guide the development of health messages for other minorities: the communitys negative reaction to the opening statement illustrates the potential tension between how researchers and communities conceptualize cultural-targeting; the importance of capturing the heterogeneity within a minority group; and incorporating, rather than negating community beliefs about disease etiology. As a next step, we will be testing whether or not the PEP can engage South Asian patients and motivate CHD prevention behaviors.

REHOSPITALIZATION RATES AND ASSOCIATED COSTS IN US MANAGED CARE PATIENTS WITH ATRIAL FIBRILLATION/ATRIAL FLUTTER Alpesh N. Amin 1; Mehul Jhaveri 2; Jay Lin3. 1University of California-Irvine, Orange, California ; 2sanofi-aventis U.S., Bridgewater, New Jersey ; 3Bruce Wong &Associates, Radnor, Pennsylvania . (Tracking ID # 10462)

BACKGROUND: Atrial fibrillation (AF) and atrial flutter (AFL) affect ~3.2 million individuals in the US, and are the leading cause of hospitalization for cardiac arrhythmia. AF/AFL impose high costs on the US healthcare system, with inpatient care being the principal cost driver. Novel antiarrhythmics show promise in reducing the risk of cardiovascular (CV) hospitalization in AF/AFL patients. However, the cost burden of AF/AFL is due not only to the initial CV hospitalization, but also to subsequent readmissions.

METHODS: In this retrospective cohort study, patients hospitalized with a primary diagnosis of AF/AFL were identified from the IMS PharMetrics Patient-Centric database (Jan 2007-March 2008). Non-AF/AFL controls were matched (1:1) to AF/AFL patients on age, gender, region, and health plan enrollment status. The date of the first qualifying (index) hospitalization of the AF/AFL patient served as the index date for the control patient. All patients had to have ~12 months continuous pre- and post-index enrollment. Rehospitalization patterns were assessed over the 12-month post-index period, and costs of initial and subsequent AF/AFL-related hospitalizations were compared. RESULTS: Overall, 5,091 patients (mean age 67.1 years; 56.8% men) were included in each cohort. AF/AFL patients had higher rates of CV comorbidity than controls. Compared with the control cohort, the AF/ AFL cohort had a significantly higher rate of all-cause rehospitalization (OR 6.4, 95% CI 5.5-7.5; P<0.0001) and CV-related rehospitalization (OR 9.2, 95% CI 7.6-11.0; P<0.0001), after adjusting for differences in comorbidity. Cumulative readmission rates for the AF/AFL cohort over the post-index period are summarized (Table). The first readmission with a primary diagnosis of AF/AFL involved a longer hospital stay than the index hospitalization (mean 4.5 vs 3.9 days; P<0.05) and higher costs (mean total charge US$ 32,132 vs 26,669; P<0.001). CONCLUSION: Hospitalized AF/AFL patients experience high rates of CV and AF/AFL-related readmission, particularly within the first 30 and 90 days. Subsequent AF/AFL-related readmissions incur higher costs than the initial AF/AFL hospitalization.

PROVIDING SHELTER FROM THE STORM: CHARACTERISTICS OF INFORMAL CAREGIVERS FOR THE HOMEBOUND ELDERLY Ania Wajnberg 1; Kristofer L Smith 1; David Russell 2; Joseph Ross 3; Alex Federman1. 1Mount Sinai School of Medicine, New York, New York ;
2Visiting Nurse Service of New York, New York, New York ; 3Yale School of Medicine, New Haven, Connecticut . (Tracking ID # 10469)

BACKGROUND: Informal caregivers, defined as unpaid friends or family members who arrange or oversee needed services because of functional disabilities, provide the majority of support for homebound adults. Caring for homebound adults may expose informal caregivers to considerable physical and emotional stress. We

therefore conducted a survey of informal caregivers of the homebound elderly to examine their level of caregiver burden, depression and satisfaction with care. METHODS: Between June and November 2010, we recruited home-bound patients newly enrolled in two home-based care programs, the Mount Sinai Visiting Doctors (MSVD) program and the Visiting Nurse Services of New York Long-term Home Health Care Program (Lombardi). We included patients aged >65 who were English- or Spanish-speaking, were able to provide consent, and had difficulty leaving their homes. All enrolled homebound patients were screened for the presence of an informal caregiver. Caregivers were surveyed and characterized with respect to socio-demographic characteristics, employment status, and time spent in the caregiving role. Caregiver burden was measured using the Zarit Burden Scale with severe burden defined as a total score >24 points; presence of depression was measured using the Center for Epidemiologic Studies Depression scale (CES-D) with definite depression defined as a total score greater than 9. Caregiver level of satisfaction with the medical care the patients they cared for were receiving was measured using the Patient Satisfaction Questionnaire 18 (PSQ-18). RESULTS: Of 65 homebound patients interviewed, 37 (52%) identified informal caregivers and we recruited 34 caregivers (92%) for interviews. Of the caregivers interviewed, a large majority were female (74%) and were adult children of the patient (77%). Twenty three (68%) lived with the patient. Fifteen (44%) were working full time (>40 hours/week), and 4 (12%) worked part time. Six (18%) were retired, and 6 (18%) were unemployed. Eighteen (53%) had been caring for their relative/friend for over 5 years and 11 (32%) for 25 years. The majority (61%) reported spending over 20 hours per week caring for their relative/friend. On the Zarit burden scale, 12 (35%) met criteria for severe caregiver burden, and on the CES-D, 32% met criteria for definite depression. In terms of satisfaction with medical care for their relative/ friend, the mean score was 63 (SD 13, range 3888) on the PSQ-18 (range from 18 [least satisfied] to 90 [most satisfied]).
CONCLUSION: A high proportion of caregivers of homebound elderly patients meet criteria for severe burden and depression. As the number of homebound seniors grows, it will be increasingly
important to identify interventions for caregivers that can decrease burden and lessen the societal impact of illness and unemployment in the caregiving population.

ELECTRONIC PRESCRIBING WITH FORMULARY DECISION SUPPORT REDUCES PATIENT COPAY AMOUNTS Joshua Pevnick 1;
Steven Asch 2; Ning Li 3; Douglas S Bell4. 1Cedars-Sinai Health System, Los Angeles, California; 2VA Greater Los Angeles Health-care System, Los Angeles, California; 3Biostatistics Core, Samuel Oschin Comprehensive Cancer Institute, Cedars-Sinai Health System, Los Angeles, California; 4RAND Corporation, Santa Monica, California. (Tracking ID # 10481)

BACKGROUND: Given the many types of health insurance that a patient may have, and the different preferred medications that each insurance company may offer, it can be difficult for a prescribing physician to know which medication will be least expensive for a given patient. Such knowledge is particularly important because lower out-of-pocket medication costs are associated with improved patient medication adherence. Several commercially available electronic prescribing (eprescribing) systems include formulary decision support that provides physicians with patient-specific formulary information. This information can be used to reduce patients out-of-pocket costs. Prior studies have shown that usage of e-prescribing with formulary decision support (EWFDS) is associated with increased prescribing of generic and lower formulary tiered medications. In this study, we examine actual copay data to measure the effect of EWFDS on patient copays. Furthermore, this analysis concentrates on smaller physician practices, which face the greatest challenges in the drive to increase health information technology (HIT) use.

In late 2004, a statewide Blue Cross Blue Shield insurer led an initiative to offer subsidized EWFDS to high volume prescribers. In a prior publication, we identified 297 primary care physicians (PCPs) who participated in this initiative by adopting this e-prescribing system during 2005. They were compared with 1892 PCPs who were also offered the system during this time period, but did not adopt it. In this study, we compare the

pharmacy claims of these PCPs assigned health maintenance organization and point-of-service primary care patients. METHODS: We analyzed pharmacy claims for drugs dispensed during 1/1/03-7/31/06. After examining the distribution of copays, we conducted bivariate analyses to measure the associations between patient copays and several physician, patient, and claim-level characteristics. We then used a difference-in-differences robust regression (DIDRR) approach to examine changes in copay amounts before and after PCPs began to use EWFDS. Adopting PCPs were categorized into three levels of e-prescribing usage (020%, 2050%, and >50%); a fourth group was comprised of non-participating PCPs. Because there was no

date of e-prescribing adoption for non-participating PCPs, we assigned each non- participating PCP a synthetic adoption date by random sampling with replacement from actual adopting PCPs adoption dates. Finally, we constructed a multivariate model using pharmacy claims as the unit of analysis. Because the intervention was not randomized, a participation variable was included to account for otherwise unmeasured baseline and persistent differences between the participating and non-participating PCPs. To measure the effect of EWFDS, we included extent of e-prescribing usage as the covariate of interest in the model. Robust regression was used to reduce sensitivity to outlying data points, which are common in cost analyses. Furthermore, several drug classes with extremely high costs were excluded. The analysis was adjusted for MD-level and patient-level covariates.

RESULTS: Of the 297 participating PCPs, 287 had a total of 19,907 primary care patients, who had a total of 0.5 million pharmacy claims. Of the 1892 non-participating PCPs, 1798 had 115,823 primary care patients with 2.9 million claims. 88% of PCPs practiced in groups of 5 or fewer physicians. The median copay was $10 (IQ range $5-$25). The distribution was positively skewed (mean $29.53, SD $272.58). Bivariate analyses showed copays to be negatively correlated with usage of EWFDS, later dates, extent of PCP prescribing with this insurer, and patient age, but positively correlated with median incomes of zip codes of patient homes and PCP offices ($p<0.0001$ for each correlation).

The DIDRR analysis showed that copays of non-participating PCPs primary care patients were $2.04/claim lower during the period after the synthetic start date of EWFDS, compared with decreases of $2.12/ claim for patients of 176 PCPs with 0-20% usage ($p=0.11$ when compared to non-participating PCPs before/after change), $2.93/claim for patients of 63 PCPs with 20-50% usage ($p<0.0001$),and only $1.80/ claim for patients of 48 PCPs with 50-100% usage ($p=0.01$). This model did not include other covariates.

The multivariate model estimated that a change from 0 to 100% EWFDS usage was associated with a copay decrease of $0.76. This decrease was mildly tempered by an estimate that copays were $0.06 higher for PCPs who participated in the e-prescribing initiative. Copays decreased by $0.13 for each later month during the time period studied. Although each 10 years of increasing patient age was associated with an $0.83 decrease in copay, primary care patients of pediatric PCPs had copays that were $2.34 less than those of internist and family medicine PCPs. Patients from zip codes with >50% Black residents had copays $2.01 less than other patients ($p<0.01$ for all estimates cited above). CONCLUSION: For the 239 PCPs who used EWFDS 0-50% of the time, it was associated with copay decreases beyond secular trends. Paradoxically, for the 48 PCPs who used EWFDS 50-100% of the time, it was associated with a relative increase in copays, when compared to the secular trend. Multivariate linear regression of EWFDS usage showed an association with decreased copays overall. The latter finding, when combined with prior studies of EWFDS that showed increased use of generic and other lower-tiered medications, suggests that EWFDS is effective overall in achieving its goal, but that it may not be effective among technophile PCPs. One possible explanation for this difference is that technophilic PCPs may be as enamored of the newest medication technology as they are of HIT.

Most other findings were consistent with expectations. Copays decreased overall during this time period, consistent with known increased use of lower-tiered medications. Higher levels of PCP-prescribing likely increased familiarity with the insurers formulary, such that these PCPs had lower copays than PCPs with fewer

pharmacy claims from the insurer. Estimates of higher patient and physician income were associated with increased copays, suggesting that resource scarcity may drive the use of less expensive medications. Further supporting this idea was the finding that patients with more claims during the study period, which represent direct costs but are also likely
indicative of other healthcare costs and decreased wealth, had lower copays. One other possible explanation for the latter finding could be increased patient familiarity with generic medications and the concept of formularies. Lower copays among primary care patients of pediatricians and among elderly patients may be explained epidemiologically. Given that African-Americans are known to place less faith in the medical profession than other groups, lower copays may be explained by consequent higher price elasticity for medical care.

COLORECTAL CANCER SCREENING IN PATIENTS WITH HIV Florence Momplaisir 1; Kathleen Brady 2; Gia Badolato 2; Judith A. Long1. 1University of Pennsylvania, Philadelphia, Pennsylvania; 2PA Department of Public Health, Philadelphia, Pennsylvania. (Tracking ID # 10488)

BACKGROUND: As HIV positive patients live longer, they become susceptible to the development of chronic diseases and cancers. Since the introduction of antiretroviral therapy (ART) in 1995, the incidence of AIDS-defining malignancies (ADMs) has declined tremendously, whereas the frequency of non-ADMs has risen disproportionately compared to the general population. Currently, there are only two published studies describing the use of CRC screening in HIV positive patients. In both, CRC screening was found to be significantly lower in HIV positive patients compared to HIV negative patients. These studies; however, did not evaluate in detail factors associated with CRC screening. There is strong evidence that quality measures for HIV care are better met when, compared to non-expert general practitioners, patients are seen by infectious disease (ID) specialists or expert generalists. There are very few studies; however, looking at quality of primary care in these patients. Whether having a primary care physician (PCP) improves non-ADM screening in HIV positive patients is unknown. In this study we evaluate whether having a PCP is associated with higher CRC screening rates in a population of HIV positive patients.

METHODS: Study sample. Patients included in this study were selected from a larger study called the Medical Monitoring Project (MMP) led by the Pennsylvania Department of Public Health and the Center for Disease Control (CDC). MMP participants were selected based on a three-stage sampling design described elsewhere and consists of HIV patients seeking care from a diverse pool of providers in Philadelphia. Patients were included in our study if they were MMP participants aged 50 or older.

DATA SOURCE: The data were collected by means of chart abstraction. We used the National Health and Nutrition Examination Survey (NHANES) template to determine if CRC screening had been performed.

OUTCOMES: The primary outcome of interest was CRC screening defined as having a documented colonoscopy, sigmoidoscopy, barium enema, or Fecal Occult Blood Test after the age of 50. INDEPENDENT VARIABLES: Patient and provider related factors were collected. Patient factors of interest included age, gender, race, lowest and most recent CD4 counts, lowest and most recent HIV viral loads, presence of co-morbid conditions, insurance status, and history of substance abuse or alcohol use. Provider factors of interest included provider specialty (ID or Generalist) and practice type (primary care practice, single versus multispecialty care practice).

STATISTICAL ANALYSIS: Standard descriptive statistics were used to describe all potential factors associated with ever having at least one CRC screening. All variables were dichotomized. Statistical differences for CRC screening (yes/no) based on clinical and demographic factors were assessed using the 2 test. A multivariable logistic regression model was created to assess the relative strength of the various associations. All variables associated with CRC screening at p RESULTS: Out of 123 chart abstractions performed, 115 had a complete clinical record from MMP to be fully analyzed. The majority

of the population was male (71.3%), non-white (73.8%) and between the age of 50 and 59 (71.3%). Most patients had a recent CD4 count greater than 350 (69.6%), an undetectable viral load (75.6%), and no history of opportunistic infections (69.5%). 45.2% did not have a PCP. In accordance with other studies, we found that the rate of CRC screening among patients with HIV was low (49%) compared to the national rate of 62.9%. Having a documented PCP was the only variable strongly associated with CRC screening. Rates of screening were 66.7% among those with a PCP versus28.5% among those without a PCP (2 $p<0.001$). After adjusting for race, substance use, and alcohol use, the odds of getting CRC screening in those without a PCP was 0.2 (95% CI 0.09-0.51, $p<0.001$).
CONCLUSION: Patients with HIV who lack a PCP are significantly less likely to receive CRC screening. Given the improved survival among patients with HIV and the increased risk of dying of non-ADMs, it is imperative that all persons be managed with standard preventive practices regardless of HIV status. Having PCPs working in collaboration with ID specialists might help improve CRC screening rates in this population.
CORRELATION OF BLEEDING RISK WITH THE USE OF ANTICOAGULANT PROPHYLAXIS IN HOSPITALIZED MEDICAL PATIENTS Sunay Shah 1; Shital Patel 1; Hanish Singh 1; Jatin Rana 1; Eiad Sabia 1; David Paje 1; Scott Kaatz1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 10495)
BACKGROUND: Anticoagulants have been shown to be very effective at preventing venous thromboembolism (VTE) in hospitalized medical patients. However, the risk of bleeding inherent with these medications has been a significant cause of concern for most clinicians, particularly in patients whose other clinical attributes make them more likely to bleed. There is currently no standard tool to stratify the bleeding risk in patients who are being considered for anticoagulant prophylaxis. The purpose of this study is to determine if the bleeding risk, as defined by the Decousus model, predicts the use of anticoagulant prophylaxis. METHODS: Adult patients newly admitted to the general medical service were assessed, and were categorized as low or high-risk for bleeding based on the Decousus model. The rates of anticoagulant prophylaxis in these categories were then compared using the chi square test.
RESULTS: 167 patients were assessed for bleeding risk; 155 (93%) were found to be low-risk and 12 (7%) were high-risk. Clinical data required to calculate the risk was available for all the patients. 5% (7/155) of the low-risk group and 25% (3/12) of the high-risk group did not receive anticoagulant prophylaxis, $p=0.03$.
CONCLUSION: Patients who are at high risk of bleeding based on the Decousus model are less likely to receive anticoagulant prophylaxis. This risk assessment tool may be useful in evaluating patients who are being considered for anticoagulant prophylaxis.
WHAT PREVENTS ADMITTING TEAMS FROM LEAVING ON TIME? PREDICTORS OF 8-HOURS OFF IN A LARGE ACADEMIC MEDICINE RESIDENCY. Jed Gonzalo 1; Shoshana Herzig 1; Eileen Reynolds 1; Julius Yang1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 10496)
BACKGROUND: The ACGME duty hour regulations have compelled some programs to consider modifying inpatient resident staffing models to ensure compliance. Such changes, which are limited by financial resources and a fixed resident supply, may have unintended consequences on both care delivery and educational outcomes. Identifying key operational factors that predict non-compliance is an important step in structure redesign. We sought to investigate our residency programs compliance rate with the 16-hour shift/8-hours off between shifts rule and to identify workload factors associated with non-compliance.
METHODS: For our residency program, duty hour limits as applied by the Internal Medicine Residency Review Committee mandate 8 hours off between shifts. Our medicine ward teams consist of three housestaff, completing call shifts every 4th day, admitting patients from 7 am until 8:30 pm, and working until 11 pm to complete call-related duties. A
night-float team admits patients overnight. Post-call shifts start at 7 am, requiring an 11 pm departure time the

night prior to ensure 8-hours off. Between August and December of 2010, we sent an online survey to all on-call ward residents immediately after each call night during four inpatient medicine call rotations. The survey was developed to identify reasons for extended shifts, including call day characteristics, such as number of short call and total admissions, number of admissions after 5 pm, and hospital departure time. We used logistic regression to identify the independent predictors of having less than 8-hours off between shifts (departure after 11 pm).

RESULTS: One-hundred and eighty-eight on-call surveys (94% response rate) were collected. Overall, 77 of 188 on-call shifts (77 of 800 total shifts, call and non-call) were followed by less than 8-hours off. Factors associated with less than 8-hours off between shifts were >3 patients admitted per team after 5 pm (adjusted OR 6.6, 95% CI 2.5-18.0) and >6 total long call admissions per team (adjusted OR 3.4, 95% CI 1.7-7.0). A team census >6 prior to a call day (adjusted OR 1.5, 95% CI 0.7-2.9), number of short call admissions on a call day (adjusted OR1.4, 95% CI 0.7-3.0), and having an intern in clinic that day (adjusted OR 2.2, 95% CI 0.9-5.5) were not significantly associated with having less than 8-hours off between shifts.

CONCLUSION: The ACGME duty hour standards were implemented in 2003 but residency programs have struggled to comply with all recommendations. Few studies have investigated the factors contributing to extended shifts. We found multiple late-day admissions and a moderate number of long call admissions are significant predictors of extended shifts, revealing vulnerabilities to be both workload and timing-specific. The relatively low number of admissions predicting non-compliance in a 16-hour day model is cause for concern and may be compromising resident education. The 2010 mandate of 16-hour-only shifts for interns may lead to non-traditional daily admitting structures, rather than the standard long-call days. In our current 16-hour model, we have struggled to contain our number of admissions and ensure an 11 pm hospital departure time. The predictors identified will be used to inform ward model redesign.

ACCULTURATION AND PROGRESSION OF LATE-LIFE DISABILITY IN HISPANICS Jose Delgado 1; Elizabeth A Jacobs 2; Kyriakos S Marquides 3; Carlos F Mendes de Leon4. 1Georgetown University Hospital, Washington, District of Columbia ; 2University of Wisconsin -Madison, Madison, Wisconsin ; 3University of Texas Medical Branch, Galveston, Texas ; 4University of Michigan School of Public Health, Ann Arbor, Michigan . (Tracking ID # 10502)

BACKGROUND: Disability disproportionately affects the elderly. Aged Hispanics have a higher prevalence of disability than non-Hispanic whites. Little is known about the potential role of acculturation in Hispanic health. The aim of this study was to examine the relationship between acculturation and the progression of late-life disability in Hispanics.

METHODS: Data came from the Hispanic Established Populations for the Epidemiological Study of the Elderly (H-EPESE). Interviews were performed in six consecutive waves between 1993 and 2007. Data included measures for disability (Activities of Daily Living [ADLs], Instrumental Activities of Daily Living [IADLs], and a summary measure of three performance tests of basic physical functions), acculturation and socioeconomic status (income, education). Longitudinal models were used to determine the association of acculturation at baseline with each disability outcome.

RESULTS: In the 3050 participants, higher acculturation was associated with both lower ADL (p=0.004) and IADL disability (p less than0.001) and higher physical function (p less than 0.001) at baseline. Acculturation was not associated with increase in either ADL disability (p=0.40) or IALD disability (p=0.37) over time. Higher acculturation was associated with less decline in basic physical functions (p=0.03). This association remained significant after adjustment for education and income (p=0.02).

CONCLUSION: In contrast to the relationship between acculturation and other chronic conditions, our study suggests that higher acculturation may have an important protective effect on late-life disability and on decline in basic physical functions in older Hispanics.

EFFECT OF PATIENTS AWARENESS OF CAD RISK FACTORS ON HEALTH RELATEDBEHAVIORS
Naweed Alzaman 1; Siddharth Wartak 2; Jennifer Friderici 1; Michael Rothberg1. 1Baystate Medical Center, Springfield, Massachusetts; 2Cleveland Clinic, Cleveland, Ohio. (Tracking ID # 10511)
BACKGROUND: Coronary artery disease (CAD) is the leading cause of morbidity and mortality in the United States. Although many patients are aware of modifiable CAD risk factors, it is not known whether awareness of risk factors will translate into better health behaviors and control of these factors. We surveyed patients at risk for CAD and
hypothesized that knowledge of a risk factor would be associated with better control of that risk factor.
METHODS: We administered a cross-sectional, anonymous survey to 2200 patients aged >40 years attending 4 general medicine practices and a cardiology clinic in Western Massachusetts. The paper and pencil survey consisted of the following sections: demographics, co-morbidities associated with CAD, health maintenance behavior, and awareness of 5 risk factors (smoking, obesity, hypercholesterolemia, hypertension (HTN) and diabetes (DM)), and 1 protective factor (exercise). Patients with specific risk factors were asked about control of that risk factor as follows: diabetes (A1CRESULTS: A total of 1702 subjects completed surveys (response rate 77%); 1504 patients had sufficient data for multivariable analysis. The sample was predominantly female (61.6%) and white (57.5%). The median age was 55 years, 78% had at least a high school degree, and 15% had CAD. No patient factors, including a history of CAD, were consistently associated with better control of all risk factors. Awareness of each risk factor was positively associated with control of that factor, but the association only reached statistical significance for exercise. The adjusted proportions of those who reported good control among those who were aware compared to those who were not aware for each factor were as follows: HTN (76.4 % versus 68.6 %, p=0.33), DM (32.5% versus19.5 %, p=0.28), high cholesterol (79.2 % versus 79.1 %, p=0.61), obese or overweight (76.4% versus 62.2 %, p=0.24), smoking (61.0% versus62.3 %, P=0.28), and exercise (48.4% versus 44.0%, P value=0.028). For patients with a history of CAD, awareness was not associated with better control of any of the factors.
CONCLUSION: Awareness that sedentary lifestyle increase the risk for CAD was positively associated with exercising 3x/week. For other risk factors, awareness was not associated with better behavior or control, even for patients with CAD. Taken alone, educational efforts to increase awareness may have limited impact on risk factor control.
THE ASSOCIATION OF ELECTRONIC HEALTH RECORD-BASED REMINDERS WITH HYPERTENSION SCREENING AND BLOOD PRESSURE CONTROL AT US PRIMARY CARE VISITS
Lipika Samal 1; Jeffrey A Linder 1; Stu Lipsitz 2; LeRoi Hicks1. 1Harvard Medical School/Brigham and Womens Hospital, Boston, Massachusetts ;
2Harvard School of Public Health/Brigham and Womens Hospital, Boston, Massachusetts . (Tracking ID # 10514)
BACKGROUND: Electronic health records (EHRs) with guideline-based reminders may improve screening and treatment for hypertension in primary care practices.
METHODS: We examined adult visits to primary care physicians using the 2007 and 2008 National Ambulatory Medical Care Survey. We assessed the association of EHR-based reminders with two outcomes 1) hypertension screening and 2) blood pressure control (BP<140/ 90 mmHg). We used multivariable logistic regression to adjust for confounding by patient factors (age, sex, race/ethnicity, diabetes), insurance type, and practice type, and used SUDAAN software to account for the complex survey design.
RESULTS: Patients had a mean age of 50 years, 33% were male, 15% had diabetes, 64% were White, 14% were Black, and 15% were Latino. Hypertension screening was performed at 91% of visits and blood pressure was controlled at 76% of visits. Screening rates were higher at visits by Latino patients than at visits by White patients (93% vs. 90%; p<0.05), at visits by patients with diabetes (93% vs. 90%; p<0.05), and at visits to community health centers compared to visits to physician-owned practices (94% vs. 90%; p<0.05). Rates of

blood pressure control were higher at visits by White patients compared to visits by Black patients (76% vs. 72%; p<0.01), at visits by patients without diabetes

(77% vs. 69%; p<0.001), at visits by women (79% vs. 70%; p<0.001), at visits paid for by private insurance compared to visits paid for by Medicare/Medicaid (78% vs. 71%; p<0.001), and at visits to practices owned by an HMO compared to visits to physician-owned practices (82% vs. 76%; p<0.05). About one-third of providers (37%) reported use of EHR-based reminders. Screening was associated with EHR-based reminders (92% vs. 90%; odds ratio [OR], 1.49; 95%CI 1.10-2.03), even after adjusting for potential confounders (93% vs. 90%; adjusted OR [AOR], 1.56; 95%CI 1.15-2.12). Blood pressure control was also associated with EHR-based reminders (78% vs. 74%; OR, 1.28; 95%CI1.08-1.52), even after adjusting for potential confounders (78% vs. 74%; AOR, 1.22; 95%CI 1.04-1.44).
CONCLUSION: In primary care, EHR-based reminders were associated with improved hypertension screening and blood pressure control. Since small improvements in blood pressure control are associated with reductions in cardiovascular morbidity and mortality, EHR-based reminders should be incorporated into intervention studies aimed at improving cardiovascular outcomes.
DIAGNOSTIC DIFFICULTY IN PRIMARY CARE: RESULTS FROM A PHYSICIAN SURVEY Urmimala Sarkar 1; Doug Bonacum 2; William Strull 2; Christiane Spitzmueller 3; Nancy Jianhua Jin 1; Andrea Lopez 1; Hardeep Singh4. 1University of California San Francisco, San Francisco, California ; 2Kaiser, Oakland, California ; 3University of Houston, Houston, Texas . (Tracking ID # 10515)
BACKGROUND: Missed and delayed diagnoses lead to significant patient harm and costs, but difficulties in diagnosing patients are not well studied in primary care where most diagnoses are made. We surveyed primary care physicians (PCPs) about diagnostic difficulty and assessed barriers to timely diagnosis in the outpatient setting. METHODS: We conducted a survey of all general internists and family physicians practicing in a large integrated health system across 10 geographically dispersed states in 2005. The survey instrument was iteratively developed and pre-tested through interviews with a sample of PCPs. An independent research firm administered the final 54-item confidential survey via mail to participants, and de-identified results for analysis. Our primary outcome (% of their patients that respondents considered difficult to diagnose), included 5 ordered responses (0%, 1% 5%, 6%10%, 11%15%, and >15%); for study purposes, we defined diagnostic difficulty as >5%. We categorized barriers in 3 conceptual domains potentially influencing timeliness of the diagnostic process in primary care: (1) information processing (information availability and time to review it); (2) subspecialty referral processes, and (3) patient characteristics (e.g. non-adherence to recommended follow-up). Cron-bachs alpha scores for the domains were 0.70, 0.81 and 0.72 respectively. For each domain, we summed the individual item responses such that higher scores indicated more optimal processes. We also collected information on respondent characteristics and explored whether physician characteristics and their ratings of information processing, referral processes, and patient barriers, were associated with perceived diagnostic difficulty.
RESULTS: Of 1817 surveys mailed, 1054 were completed (response rate 58%). Because some physicians were mostly hospital-based, we restricted our sample to 848 (80%) respondents who reported primarily practicing in the outpatient setting and had a patient panel. Respondents had been in practice for mean of 13 years and 62% were male. Half (50%) reported >5% of their patients were difficult to diagnose. Physicians with more experience reported less frequency of diagnostic difficulty (OR per 1 year decrease in experience 1.04, CI 1.02-1.06). In adjusted analyses, problems with information processing (OR 1.29, CI1.04-1.60) and referral processes (OR 1.43, CI 1.16-1.78), were
associated with greater (>5%) difficulty to diagnose, but patient barriers were not (OR 1.07, CI0.89-1.28).

Analysis of specific constructs within the two significant domains revealed that physicians who reported insufficient time to integrate clinic information and insufficient time to think carefully about diagnosis reported more frequent diagnostic difficulty. Similarly, physicians who reported that subspecialists do not provide recommendations for next steps after consultation were more likely to report diagnostic difficulty (p0.05 for difference between PCPs reporting vs. not reporting diagnostic difficulty for all constructs). CONCLUSION: Diagnostic difficulty is not uncommon among PCPs and appears to correlate with inadequate time to process diagnostic information and insufficient guidance from subspecialists. Although our study was performed prior to comprehensive electronic health record (EHR) implementation at this health system, barriers we found associated with perceived difficulty might not necessarily be mitigated by EHRs. Practice-level interventions that address these factors are needed to reduce diagnostic difficulty in primary care.

THE EFFECT OF THE NUMBER OF ADMISSIONS TO INPATIENT MEDICAL TEACHING TEAM ON PATIENT SAFETY OUTCOMES Yelena Averbukh 1; William Southern2. 1Montefiore Medical Center, New York, New York; 2Montefiore Medical Center, Sleepy Hollow, New York. (Tracking ID # 10516)

BACKGROUND: An estimated 44,000 to 98,000 preventable deaths caused by medical errors occur each year in the U.S. In teaching institutions, house staff members are involved in over half of the cases of medical errors. Excessive workload and inadequate supervision are among most commonly cited reasons for resident error. First in 2003 and then in July 2010 the Accreditation Council for Graduate Medical Education (ACGME) enacted new limits on the number of patients residents were allowed to care for with the hope that lower workload would improve the quality of care and patient safety. However an observational study of 8,529,595 Medicare recipients admitted to acute care hospitals showed that duty hour reform was not associated with any consistent improvements or worsening in mortality. In 2009 ACGME also called for Internal Medicine programs to ensure for 4:1 ratio of the learner to faculty and need for sufficient supervision and teaching during each rotation or major learning experience. In spite of the growing body of evidence suggesting that inadequate supervision of house staff is associated with sub optimal safety and care outcomes for the patients, there is very little evidence on how medical team workload affects quality of supervision and patient safety outcomes. To address this we examined the associations between the number of patients seen by a teaching team and length-of-stay, 30-day readmission, and 60-day mortality.

METHODS: In this retrospective observational study we examined all admissions to the medicine teaching service of an urban academic medical center from March 1st 2009 to June 30th 2010. Each month, approximately 18 teaching teams provide care at 2 hospitals within the medical center. First, we examined the total number of admissions seen by each team each month. Next, we defined each team as less busy (total admissions 49). Admissions were assigned to the teams without bias according to an on-call schedule. The primary outcome measures were length-of-stay, 30-day readmission, and 60-day mortality. The two patient groups were compared with respect to demographic characteristics, co-morbidities (Charlson score), severity of illness (Laboratory-based Acute Physiology Score, LAPS), and length of stay using t tests, chi-squared, and rank sum tests, as appropriate. Logistic regression models were constructed to determine the in dependent association between assignment to a busy team and readmission and mortality, after adjustment for demographic and clinical characteristics. In

additional analysis, teams were placed in to quintiles of number of admissions, and the readmission rate for each quintile was determined. RESULTS: Of 12,119 admissions examined, 6,398 (52.8 %) were assigned to the less busy teams and 5,721 (47.2 %) were assigned to busy teams. Patients assigned to busy teams were older, were more likely to be female, white, have Medicaid, and had higher LAPS score. Mean length-of-stay was not statistically different between the groups (5.2 vs 5.3 days, p=0.08). After adjustment for demographic (race, sex, ethnicity, insurance type) and clinical characteristics (LAPS and Charlson score), care by a busy team was associated with greater30-day readmission rate (OR 1.21, 95% CI 1.10-1.34). After

adjustment for demographic and clinical characteristics, care on a
busy team was not associated with increased risk of mortality (OR1.05, 95% CI 0.88-1.27). There was a significant linear association between the number of monthly admissions to teams and readmission rate (Figure 1).
CONCLUSION: Admission to a busier medical teaching team is associated with 21 % increased odds of 30-day readmission. We found no association between admission to a busy team and length of stay or 60-day mortality. Further research is needed to determine if controlling for the number of monthly admissions to inpatient teaching teams will improve readmission rates.
POST-OPERATIVE HIP FRACTURE CARE IN AN ACUTE CARE FOR ELDERS (ACE) UNIT Keith Primeau 1; Edgar Pierluissi2. 1University of Arizona, Tucson, Arizona; 2University of California, San Francisco, San Francisco, California. (Tracking ID # 10522)
BACKGROUND: Over 300,000 Americans suffer a hip fracture each year, the majority over age 65. The Acute Care for Elders (ACE) model of hospital care for older adults can improve function at discharge and reduce nursing home admission for medical patients. The efficacy of this

model of care has not been evaluated in patients after hip surgery. An ACE unit at San Francisco General Hospital, a public hospital serving a low-income, diverse population has cared for post-operative hip surgery patients since July, 2007. We describe patient characteristics and ambulation status at discharge, length of stay, and discharge location of patients receiving care in an ACE unit to those receiving usual care. METHODS: Retrospective chart review of patients age 65 or greater admitted to general medical-surgical wards after hip fracture repair from July 2007 to June 2010. Patients with multiple fractures, multiple injuries secondary to trauma, or who were transferred or managed nonoperatively were excluded. We compare 56 patients admitted to an ACE unit and 96 admitted to usual care.
RESULTS: The average age of patients admitted to an ACE unit was 80 years and 79 for those admitted to non-ACE units. Seventy-six percent of ACE patients were female compared to 63% admitted elsewhere. The ethnicity of patients was 48% Asian, 31% White, 9% Latino and 12% African-American, compared to 33%, 38%, 13%, and 9%, for ACE and non-ACE units, respectively. Forty percent of patients on the ACE unit had an open reduction and internal fixation, 34% a closed reduction and internal fixation, and 26% a partial total hip replacement, compared to 51%, 24%, and 24%, respectively. At discharge, compared to baseline, 50% of ACE patients had declined in ability to ambulate, whereas 73% of non-ACE patients declined in ability to ambulate. (p=0.03) The average length of stay was 10.0 days and10.5 days (p=0.70) in the ACE and non-ACE units, respectively. Patients in the ACE unit were discharged home 26% of the time compared to 17% for patients discharged from non-ACE units (p=0.23). CONCLUSION: In post-operative hip fracture patients, an ACE model of care serving a low-income, diverse population resulted in increased ability to ambulate and trends toward increased discharge to home.
COMPARISON OF POSITIONAL SYMPTOMS AND PREFERRED SLEEPING ANGLE WITH THORACIC FLUID CONTENT IN PATIENTS WITH HEART FAILURE Anne S. Kemble 1; Bruce A.G. Soll 2; Khung Keong Yeo 3; James W. Davis 4; Todd B. Seto 2; Irwin J. Schatz2.
1University of Hawaii John A. Burns School of Medicine, Honolulu, Hawaii ; 2Department of Medicine, John A. Burns School of Medicine, University of Hawaii, Honolulu, Hawaii ; 3Division of Cardiovascular Medicine, University of California, Davis Medical Center, Sacramento, California ; 4John A. Burns School of Medicine, University of Hawaii, Honolulu, Hawaii . (Tracking ID # 10527)
BACKGROUND: Orthopnea and paroxysmal nocturnal dyspnea (PND) are among the cardinal manifestations of heart failure. The number of pillows a patient sleeps on indicates a preferred angle of recumbency, and is

thought to be a measure of orthopnea severity. These symptoms are believed to result from position-related redistribution of fluid from the splanchnic circulation and lower extremities into the thoracic circulation, leading to pulmonary alveolar and interstitial edema, yet there is little data to support this assumption. This study compares symptoms of orthopnea, PND, and preferred sleeping angle to thoracic fluid content measured by Impedance Cardiography (ICG) in patients with systolic heart failure.
METHODS: 25 patients with stable heart failure and ejection fraction less than 40% completed a questionnaire that included screening for orthopnea and PND. Overnight polysomnography was performed. Each patient fell asleep at their preferred sleeping angle and then slept at 0, 15, 30, and 45 degrees in random order. Thoracic fluid content (TFC, a surrogate marker of total thoracic fluid) was recorded continuously using ICG. Pearson correlation was used to compare continuous variables, and nonparametric one-way analysis of variance was used to compare continuous variables with groups.
RESULTS: 4 patients reported a history of orthopnea, and 6 patients reported PND. Preferred sleeping angles ranged from 0 to 32 (mean 12). The thoracic fluid content index (TFCI, a calculation adjusting for body surface area) was found to have a statistically significant decrease with increasing angle in only 3 of the 25 patients (slope 0.05, 0.043, and 0.039 with p=0.011, 0.028, and 0.0001 respectively). Yet all 3 of those patients selected 0 as their preferred sleeping angle, indicating that the changes in TFCI were not likely clinically significant. The other 22 patients had no significant change in TFCI with angle. Overall there were no significant correlations between TFCI and preferred sleeping angle (p=0.18), preferred sleeping angle and orthopnea (p=0.93), TFCI and PND (0.42), or TFCI and orthopnea (p=0.93). The primary study had been powered to assess respiratory events with changes in sleeping angle, and was not designed to have statistical power for this secondary study.
CONCLUSION: Symptoms thought to result from position-related redistribution of fluids into the thoracic circulation did not show the expected correlation with levels of TFC measured by ICG. Furthermore, TFC did not change significantly with angle of recumbency. Recent studies suggest that ICG measurement of TFC is a sensitive indicator of chest fluid changes, net thoracic fluid levels, and rales on pulmonary exam. This study challenges the assumption that positional symptoms in patients with heart failure are solely the result of redistribution of fluids into the thoracic space. Given the impact of these symptoms on patient assessment and clinical decision making, further research is needed on the relationship between body position and symptoms of heart failure.
BURNOUT IN INTERNAL MEDICINE RESIDENTS IS ASSOCIATED WITH DECREASED WELLNESS AND LACK OF MINDFUL AWARENESS Rachel Swigris 1; Allan Prochazka 2; Ravi K Gopal 3; Debra Sorensen 2; Michael Craine 2; Jessica Campbell4. 1University of Colorado, Denver, Colorado ; 2Veteran Affairs Medical Center, Denver, Colorado ;
3Denver VAMC, Denver, Colorado ; 4Denver Health Medical Center, Denver, Colorado . (Tracking ID # 10539)
BACKGROUND: Burnout is prevalent among internal medicine residents (IMR) and has been linked to self-reported suboptimal patient care, perceived medical errors and deferred clinical decision-making. In practicing physicians, training in mindfulness improves well-being. There is a paucity of data on interventions to prevent or decrease burnout in residents and no published data on mindfulness training in IMR. We hypothesized that burnout is associated with impaired mindfulness and decreased well-being among IMR.
METHODS: We administered a postal survey to 1st-, 2nd- and 3rd-year IMRs at the University of Colorado Denver School of Medicine. The Maslach Burnout Inventory was used to assess two components of burnout, emotional exhaustion (EE) and depersonalization (DP). We defined burnout as EE >26 or DP >9. We assessed mindfulness using the Baer Five Facet Mindfulness Questionnaire (FFMQ), for which the Nonreact facet is scored 735, the other 4 scored 840, and for all 5 facets, higher scores=greater mindfulness. We measured wellness using the 6-item Brief Resident Wellness Profile (BRWP) scored 15; higher scores=greater wellness. We used Pearson product moment correlation and multivariable linear regression (MVLR) to examine the relationship between burnout and wellness or mindfulness. For the MVLR, we built a model for each of the two

burnout facets (EE and DP) and included as potential predictors in each model all variables with p<0.15 on bivariate analysis. Backward elimination was used to yield the most parsimonious models.
RESULTS: The response rate was 60.9% (98/161). Respondents were evenly distributed among PGYs, and 48% of respondents were female.

Survey results are shown in Table 1. 46.9% of respondents were burned out. Various facets of mindful awareness and wellness were associated with burnout (Table 2). In the MVLR analyses, wellness and the Act aware Facet of Mindfulness were independent predictors of both EE and DP.
CONCLUSION: Nearly half of our IMR were burned out. IMR burnout was associated with impairments in well-being and mindfulness. Wellness and mindfulness were independent predictors of burnout. Prospective studies are needed to determine whether interventional programs in mindfulness training will decrease burnout and improve wellness.
IATROGENIC PNEUMOTHORAX: ANALYSIS OF A NEW AHRQ MEASURE Debra Lurns 1; Tracey Smith 1; Brent Petty2. 1Johns Hopkins Hospital, Baltimore, Maryland; 2Johns Hopkins University School of Medicine, Baltimore, Maryland. (Tracking ID # 10544)
BACKGROUND: CMS introduced nine safety measures via AHRQ as part of its pay-for-performance (P4P) program for FY10. One of the measures was iatrogenic pneumothorax (IP). At our institution, the observed/expected rate for IP had been unexpectedly high. The objective of this project was to identify the causes for IP and to determine whether these cases had been accurately identified through the coding and electronic selection process.
METHODS: The University Health Consortium (UHC) database identified cases coded as having IP at our hospital in CY08, FY09 and FY10. Each identified case was extensively reviewed (including progress notes, operative and procedure notes, radiology reports and discharge summary) by two quality improvement specialists and a physician to determine the presence and cause of IP. Our strict definition required verification that pneumothorax (PTX) was not present on admission but later was reported by a radiologist in a formal x-ray report. Additional provider input was elicited on specific cases when needed to clarify events surrounding the PTX.
RESULTS: For CY08, 62 cases were identified. Of these, 12 (19%) were excluded because they were lung lobectomies, 4 others related to cardiovascular surgery, (excluded per updated AHRQ policy in June 2009), 4 related to surgery with expected PTX because of the surgical approach, 3 because no radiology report documented PTX, 3 present on admission, and 1 was a pleural effusion (excluded per AHRQ policy). That left, at most, 35 patients (56%) who actually had IP. Of these, 12 were related to central line (CL) placement and 6 were related to scalenectomy (S), a surgery done frequently at our hospital
with a 20-35% rate of PTX. For FY09, 64 cases were identified. Of those, 15 (23%) were excluded because they were associated with lung lobectomies, 5 because of pleural effusion, 2 related to thoracoscopic procedures (per AHRQ policy), 3 related to surgeries expected to have PTX, and 3 because no radiology report documented PTX. Thus, at most, 36 patients (56%) had IP. Of these, 10 were related to CL and 9 were related to S. For FY10, only 36 cases were identified, a 59% reduction from FY09. With improved software for searching discharge records, no cases were excluded for lobectomy, thoracoscopy or pleural effusions. Of these 36 cases, 2 were excluded because there was no radiographic confirmation of PTX, 1 was a hospital coding error, and 6 were surgical cases with expected PTX, leaving, at most, 27 cases of IP, of which 8 were related to CL and 7 were related to S. In each time period, there were several surgical procedures likely related to PTX but not expected to have this complication in large numbers. Examples included thoracic spinal surgery, open right partial nephrectomy and peritoneal stripping of metastatic cancer.
CONCLUSION: Relying on software searches of coded discharge information can overestimate the incidence of IP. Improvement of both software and coding practices can reduce this error. For patients with true IP, central

line placement was the most common cause, but accounted for 12 or fewer cases during each period, with a downward trend over time. Scalenectomy may put our institution at risk for inflated observed/expected IP if that unusual surgical procedure (without its own ICD code) is not adjusted for in observed/expected calculations. The rare but explicable incidence of IP in other surgical procedures near to or involving the diaphragm must also be adjusted for in those calculations. Without rigorous methodological intervention, IP will continue to be overestimated and will make inter-institutional comparisons potentially invalid.

ARE HEALTH CARE PROFESSIONALS ADVISING A LOW-FAT DIET TO PATIENTS WITH DIABETES OR DIABETES RISK FACTORS? Ingrid Lobo 1; Danielle Loeb 1; Vahram Ghushchyan 1; Amy G. Huebschmann1. 1University of Colorado, Denver School of Medicine, Aurora, Colorado. (Tracking ID # 10550)

BACKGROUND: Over 17.5 million people are diagnosed with type 2 diabetes mellitus (DM) in the U.S. and >90% of U.S. adults with DM have type 2 DM. Maintaining low cholesterol levels is a key aspect of cardiovascular prevention for people with type 2 DM or risk factors for type 2 DM (e.g. hypertension, overweight). The American Diabetes Association (ADA) recommends health care providers counsel their patients with or at risk for type 2 DM to follow a low-fat diet (Despite this recommendation, the extent to which populations with or at risk for type 2 DM receive low-fat diet advice from health care professionals remains unclear. We assessed this issue using data from the federally sponsored, nationally representative survey of the non-institutionalized U.S. population (Medical Expenditure Panel Survey, MEPS). METHODS: MEPS collects data on sociodemographic information and chronic health conditions, among other endpoints. Survey data are obtained from patient self-report and insurance claims. Between 2001 and 2007, all MEPS participants were asked the following question: Has a doctor or other health professional ever advised you to eat fewer high-fat or high cholesterol foods? We designated participants DM status as + DM or no DM using MEPS self-report (data on diabetes type were unavailable). We also quantified participants ADA-designated risk factors for type 2 DM. ADA-designated type 2 DM risk factors measured in MEPS included: age >45 years, BMI >25 kg/m2, physical inactivity, members of a high risk ethnic population (non-Caucasian), hypertension, hyperlipidemia, and a history of cardiovascular disease. We first measured the unadjusted prevalence of low-fat diet advice by DM status and presence or absence of DM risk factors. Next, we performed a multivariate logistic regression analysis to determine the odds of advice to eat a low-fat diet for MEPS participants with DM vs. no DM. Finally, we performed separate multivariate logistic regression analyses to determine the odds of advice to eat a low-fat diet for participants with incrementally higher numbers of type 2 DM risk factors (e.g. 1 risk factor, 2 risk factors). Each regression analysis also controlled for gender, education, income, census region, smoking status, and the generalized chronic illness morbidity index. RESULTS: Unadjusted rates of advice to eat a low-fat diet were lowest in individuals reporting no risk factors or DM (7.50.3%), intermediate in the presence of type 2 DM risk factors (32.30.3%), and highest for participants reporting DM (71.10.7%). In multivariate regression analysis, participants reporting DM had 1.98 greater odds of receiving low-fat dietary advice as compared to participants reporting no DM. As the number of risk factors for type 2 DM increased, the adjusted odds of receiving advice to eat a low-fat diet increased in an accelerated fashion (reference: OR=1.0 for no type 2 DM risk factors; 2 risk factors, OR=2.41 [95% CI=2.16-2.70]; 3 risk factors, OR=7.78 [95% CI=6.98-8.69]. CONCLUSION: In keeping with national guidelines, the majority of patients with DM receive low-fat dietary advice from health care professionals. However, only 1/3 of patients with type 2 DM risk factors report receiving low-fat dietary advice. Health care professionals should provide low-fat dietary counseling more often to their patients with risk factors for type 2 DM.

A NOVEL CLINICAL DECISION SUPPORT TOOL IMPROVES PRIMARY CARE TREATMENT OF CHRONIC KIDNEY DISEASE David Feldstein 1; Douglass Wiegmann 2; Brian Arndt 1; Scott Hetzel 1; Thomas Gabert 3;

Paul Smith1. 1University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin ; 2University of Wisconsin-Madison, Madison, Wisconsin ; 3Marshfield Clinic, Minocqua, Wisconsin . (Tracking ID # 10552)
BACKGROUND: Twenty six million Americans suffer from chronic kidney disease (CKD). Early intervention can prevent complications and delay progression to end stage renal disease. Despite the high prevalence and associated morbidity, patients are not receiving evidence-based care for the treatment and prevention of CKD. Clinical decision support (CDS) can improve guideline adherence and quality of care. The objectives of this study were to develop a CKD clinical decision support tool (Kidney Care) that improves primary care providers adherence to CKD guidelines and test its feasibility in primary care clinics.
METHODS: Kidney Care is a web-based CDS tool designed to support primary care providers (PCPs) care of CKD patients. Kidney Care was designed using human factors principles and tested for usability. The tool is comprised of four components: 1) patient specific guideline recommendations; 2) brief point of care clinician informational resources; 3) electronic Nephrology consultation; and 4) patient educational materials. Twenty PCPs and their medical assistants from six Wisconsin clinics were trained to use Kidney Care. The PCPs and medical assistants used Kidney Care for 25 of their patients with stage 3 CKD over a six month period. Kidney Care use was recorded. The number of unmet guideline criteria for each patient was recorded at enrollment and completion of the six months. PCPs completed a 19 item multiple choice CKD knowledge test and a 44 item CKD self-efficacy survey prior to training and at study completion. Each self-efficacy item was rated on a scale of 0 (not at all confident) to 10 (extremely confident) with the total score being the sum of all items. Changes in the number of unmet guideline criteria were analyzed using the Wilcoxon-signed rank test. Spearman correlation coefficient was used to determine the effect of frequency of PCP and medical assistant access to a patients guideline page on changes in unmet guidelines. Changes in overall CKD knowledge and self-efficacy were analyzed using paired T-tests. Spearman correlation coefficients were calculated for effect of PCP tool usage on changes in PCP CKD knowledge and self-efficacy.
RESULTS: Eight (40%) of the PCPs were trained in Internal Medicine and 12 (60%) in Family Medicine. PCP clinics were urban (35%), suburban (20%) and rural (45%). Sixteen (80%) PCPs completed pre and post CKD knowledge and self-efficacy questionnaires. Sixty seven patients were enrolled in the study and had a median of 6 (Interquartile Range (IQR) 47) unmet guideline criteria on enrollment. The median unmet guideline criteria at study conclusion was 4 (IQR 1.5-6) with a median decrease in unmet guidelines of 0 (IQR 3-0) ($p<0.001$). Tool usage correlated with a decrease in unmet guidelines (Rho 0.581, $p<0.001$). PCP CKD knowledge test scores improved by a mean of 1.2 questions (SD 2.3, $p=0.06$). Tool usage correlated with improvement in test scores (Rho 0.584, $p=0.02$). Overall self-efficacy scores increased by an average of 37.9 (95% CI: 15.3-60.4, $p=0.003$). However, tool usage did not correlate with self-efficacy score changes (Rho 0.11, $p=0.75$).
CONCLUSION: The implementation of a CKD clinical decision support tool was feasible in a range of primary care clinics. This novel tool was able to decrease the number of unmet guidelines per patient. Tool usage was associated with an increase in PCP knowledge about CKD, but not self-efficacy. This is an important step in providing PCPs with tools to care for their patients with CKD. Future studies will determine if Kidney Care can improve patient outcomes.
GENDER AND RISK OF HOMELESSNESS AMONG OPERATION ENDURING FREEDOM/OPERATION IRAQI FREEDOM VETERANS Oni Blackstock 1; Cynthia Brandt 2; Sally Haskell 3; Rani Desai4. 1VA Connecticut Healthcare System/Yale Robert Wood Johnson Foundation Clinical Scholars Program, New York, New York ; 2VA Connecticut Healthcare System/Yale Center for Medical Informatics, West Haven, Connecticut ; 3VA Connecticut Healthcare System/Yale School of Medicine, West Haven, Connecticut ; 4VA Connecticut Healthcare System/Yale Robert Wood Johnson Foundation Clinical Scholars Program, West Haven, Connecticut . (Tracking ID # 10556)

BACKGROUND: Compared to men, women are disproportionately underrepresented among homeless persons

and, more specifically, among homeless Veterans. We sought to determine risk of homelessness by gender among Operation Enduring Freedom/Operation Iraqi Freedom (OEF/OIF) Veterans, the Veteran cohort with the largest proportion of women.
METHODS: OEF/OIF Veterans with at least one Veterans Health Administration (VHA) visit were compared by gender. Cox proportional hazards models were used to determine the relative risk of homelessness by gender, adjusting for relevant demographic and clinical variables. Time to homelessness was defined as the time from military separation to the first VHA visit at which the Veteran used specialized VA homeless program services or received a V60.0 ICD-10 diagnostic code, indicating lack of housing.
RESULTS: Of 462,098 Veterans, 9,170 (2.0%) were identified as homeless, 1,109 women (2.0%) and 8,061 men (2.0%). Homeless women were more likely to be younger (27.07.2 vs 27.78.0 years, p CONCLUSION: Contrary to data indicating female gender is protective against homelessness, we found women and men OEF/OIF Veterans to be at equal risk. Furthermore, the characteristics of homeless women and men OEF/OIF Veterans differed. These differences may speak to the need for gender-specific interventions to prevent homelessness among OEF/OIF Veterans.
IS APPEARING CHRONICALLY ILL A SIGN OF POOR HEALTH? Shail Rawal 1; Stephen W. Hwang 2; Mina Atia 3; Rosane Nisenbaum 3; Dwayne E. Pare 4; Steve Joordens5. 1Department of Medicine, University of Toronto, Toronto, Ontario ; 2Division of General Internal Medicine, Department of Medicine, University of Toronto and Centre for Research on Inner City Health, The Keenan Research Centre in the Li Ka Shing Knowledge Institute of St. Michaels Hospital, Toronto, Ontario ; 3Centre for Research on Inner City Health, The Keenan Research Centre in the Li Ka Shing Knowledge Institute of St. Michaels Hospital, Toronto, Ontario ; 4Centre for Computational Cognitive Neuroscience, University of Toronto Scarborough, Toronto, Ontario . (Tracking ID # 10557)
BACKGROUND: Physicians are taught to begin the physical examination with a general inspection that often includes an assessment of whether the patient appears chronically ill. This practice is grounded in the assumption that a patients apparent health status correlates with their actual state of health. However, the evidence for this component of the physical examination is limited. The goal of this study is to determine if the assessment by a physician that a patient appears chronically ill is a sensitive or specific sign for the detection of poor health status. METHODS: This cross-sectional study involved 126 adult outpatients recruited from four primary care clinics and one general internal medicine clinic at an academic medical institution. The health status of each patient participant was determined using the self-administered version of the 12-Item Short Form Health Survey (SF-12). A photograph was taken of each participant, showing a frontal view of the persons face with a neutral facial expression. Physician participants (n=71 internal medicine residents and general internal medicine faculty) viewed the patients photographs using an online program. The order of presentation of the photographs was randomized for each physician. With the patients age provided, physicians were asked to assess whether or not the patient appeared chronically ill. For each physician participant, we determined the sensitivity and specificity of appearing chronically ill for the detection of poor health. We examined two different criteria for the definition of poor health: SF-12 physical health score >1 SD or >2 SD below the age group norm. For the entire group of physicians, the median and inter-quartile range (IQR) for sensitivity, specificity, positive likelihood ratio, and negative likelihood ratio were calculated.
RESULTS: Among 126 patient participants, 42 (33%) had an SF-12 physical health score >1 SD below age group norm, and 22 (18%) had a score >2 SD below the age group norm. Physicians rated a mean of 29% of patients as appearing chronically ill (range, 4-52%). When poor health status was defined as an SF-12 physical score >1 SD below age group norms, the median sensitivity was 35.7% (IQR 28.6-47.6%), median specificity 77.4% (IQR 69.0-83.3%), median positive likelihood ratio1.57 (IQR 1.33-2.13), and median negative likelihood ratio 0.82 (IQR0.74-0.89). When poor health status was defined as an SF-12 physical score >2 SD below age group norms, the median sensitivity was 40.9% (IQR 31.8-54.5%), median specificity 74.0% (IQR 66.3-82.7%),

median positive likelihood ratio 1.67 (IQR 1.46-2.10), and median negative likelihood 0.75 (IQR 0.68-0.87). CONCLUSION: A physicians assessment that a patient appears chronically ill has poor sensitivity and modest specificity for the detection of poor health status. The likelihood ratios associated with appearing chronically ill indicate that this assessment has very limited diagnostic value.

CHEMOTHERAPY USE IN LUNG CANCER AT THE END OF LIFE: PREDICTORS AND VARIATION IN USE

Jonas B Green 1; Martin F Shapiro 2; Susan Ettner 2; Jennifer Malin 3; Mitchell D Wong2. 1UCLA Medical Center, Los Angeles, California; 2UCLA Division of GIM/HSR, Los Angeles, California; 3West Los Angeles VA, Los Angeles, California. (Tracking ID # 10563)

BACKGROUND: Adverse effects of chemotherapy in lung cancer, when administered near the end of life, often overshadow any benefits and are associated with considerable direct and indirect economic cost. Variation in rates and predictors of chemotherapy administration in lung cancer patients are not well understood, but have significant implications for the societal and individual patient costs and benefits of health care delivered near the end of life.

METHODS: We examined linked SEER-Medicare claims data to identify 51,905 patients ages 65+ who received chemotherapy for lung cancer. We included those who were diagnosed with lung cancer between 1995 and 2005 and had traditional Medicare parts A and B coverage for at least 12 months prior to first lung cancer diagnosis and until three years after diagnosis or until death. We calculated rates of chemotherapy use within 30 and 14 days of death among those who received any chemotherapy. We then used logistic regression to identify the predictors of end of life chemotherapy treatment. The model predictors were race, sex, age, U.S. birth, year of diagnosis, Medicaid enrollment any time after diagnosis, marital status, time since diagnosis, and comorbidity, controlling for fixed effects of geographic SEER site. RESULTS: Among the 46,603 (89.8%) who died within three years of diagnosis, 31.5% received chemotherapy within 30 days of death and15.9% received chemotherapy within 2 weeks of death. Marriage (OR=1.12, p=.014), diagnosis from 1997 through 2004 (OR=1.17 to 1.48, p<.001 to .034 for each year), and recency of diagnosis (OR=3.9 to 24.8, decreasing each 6 months past diagnosis, p<.001 for each interval) were significant predictors of higher rates of chemotherapy receipt during the last 30 days of life, whereas female sex (OR=.90, p<.001), black race (OR=.85, p=.001), Medicaid coverage (OR=.70, p<.001), and older than 75 (OR=0.88 age 75 79, 0.79 age 8084, 0.67 age 85+, p<.001 for each cohort) predicted lower rates. Divorce, widowhood, unknown marital status, Asian, Hispanic, or other race, US birth, comorbidity score, and age (7074) were not significant predictors. Pseudo-R2 was 0.14. ORs for chemotherapy within 2 weeks of death are similar, although marriage and diagnosis in 1998 no longer achieve significance while diagnosis in 1996 does.

CONCLUSION: Despite the high mortality rate of lung cancer and considerable side effects associated with chemotherapy, a substantial

proportion of Medicare patients continue to undergo treatment even in their last days of life. Although rates decline with age, this is true even among the oldest old (85+). Whereas expensive therapies generate difficult questions at the nexus of medical economics and ethics if treatment has measurable benefit, the question should be moot at the stage of illness when treatment has very limited or no benefit and when resources ought to be directed toward improving comfort and the quality of the final days of life. It is unclear why such aggressive treatment is continued so often in end-stage lung cancer. Altogether the variables examined here account for little of the variability in chemotherapy use near the end of life. The impact of physician factors, including demography and preferred practice habits, while not examined here may be an important source of variations in care.

HOW SAFE IS YOUR NEIGHBORHOOD? PERCEIVED NEIGHBORHOOD SAFETY AND FUNCTIONAL

DECLINE IN OLDER ADULTS Vivien K. Sun 1; Irena Stijacic Cenzer 2; Brie A. Williams2. 1School of Medicine, University of California at San Francisco, San Francisco, California ; 2Division of Geriatrics, University of California at San Francisco and San Francisco VA Medical Center, San Francisco, California . (Tracking ID # 10564)

BACKGROUND: Perception of living in an unsafe neighborhood could lead older adults to limit their physical activity, leading to deconditioning and functional or mobility decline (Functional decline). Functional decline is a strong predictor of health care costs, health care utilization, poor quality of life, and mortality in older adults. While perception of living in an unsafe neighborhood is associated with baseline physical inactivity and 8-year mobility impairment in older adults, these studies were small, geographically limited, or did not assess other forms of functional decline such as impairment in the Activities of Daily Living (ADL). Our goal was to assess the relationship between perception of neighborhood safety and long-term functional decline in older Americans.

METHODS: Our cohort included 18,043 adults aged 50 or older who participated in the 1998 Health and Retirement Study, a nationally representative study of older persons. Our predictor was perception of neighborhood safety [Would you say the safety of your neighborhood is excellent, very good, good, fair or poor?]; categorized into 3 groups: very safe (excellent/very good), moderately safe (good), and unsafe (fair/ poor). Our primary outcome was 10-year functional decline, defined as any new difficulty or dependence in an ADL (eating, dressing, transferring, toileting, and/or bathing); any new difficulty in walking several blocks and/ or climbing one flight of stairs; or death. We assessed the relationship between perceived neighborhood safety and functional decline, whether sociodemographics and health status confounded the relationship, and whether the association between perceived neighborhood safety and functional decline differed by baseline functional status.

RESULTS: The mean age was 67 years (range 50105), 44% were men, 77% white, 71% received a high school education or higher. At baseline,63.7% of participants were independent in all ADL and mobility measures. Overall, 65.1% perceived their neighborhood to be very safe,24.8% perceived it as moderately safe, and 10.1% perceived it as unsafe. Subjects in the very safe group were more likely to be male, white, have higher wealth, fewer chronic conditions, and lower baseline functional impairment (all $P<0.001$). Over 10 years, 57.3% experienced functional decline, including 53.4% of subjects who perceived their neighborhood to be very safe, 63.4% who perceived their neighborhood to be moderately safe, and 67.6% unsafe, $P<0.001$. After adjustment for age, race, gender, marital status, education, income, net worth, baseline medical conditions and functional status, there was still a significant association between perceived neighborhood safety and 10-year functional decline for those who considered their neighborhood moderately
safe (OR 1.22; 95% CI 1.11-1.34) or unsafe (OR 1.27; 95% CI 1.10-1.46) compared to the very safe group. The association between perceived safety and functional decline was strongest for those who were independent at baseline [moderately safe group OR 1.32 (95% CI1.18-1.48), unsafe group OR 1.70 (95% CI 1.42-2.04) compared to the very safe group].

CONCLUSION: Overall, 1 in 3 older Americans reported that their neighborhood was unsafe or moderately safe and this perception was associated with increased 10-year functional decline, especially for those who were independent at baseline. Our findings suggest that asking older patients about their neighborhood safety may provide important information about risk of functional decline that is not captured by sociodemographics, health conditions, and baseline functional status. Moreover, public health interventions to promote physical activity while addressing safety concerns could help to reduce long-term functional decline in independent older adults.

SEVERITY-OF-ILLNESS STRONGLY PREDICTS DEVELOPMENT OF VENOUS THROMBOEMBOLISM IN MEDICAL IN-PATENTS Richard H White 1; Beate Danielsen 2; Daniel J Tancredi 1; Calvin Hirsch 1; Scott Kaatz3. 1University of California, Davis, Sacramento, California ;
2Health-Information-Solutioins, Rocklin, California ; 3Henry Ford Hospital, Detroit, Michigan . (Tracking ID # 10567)

BACKGROUND: A major national quality improvement initiative is the prevention of venous thromboembolism (VTE) in hospitalized patients. The Joint Commissions core VTE measure includes assessing the risk of VTE shortly after hospital admission and at the time of entry into an intensive care unit. Unfortunately, data regarding risk factors for VTE events that develop during a medical hospitalization (Hosp-VTE) are meager. Most reviews cite single risk factors such as older age or specific disease states, such as cancer or heart failure. A proprietary measure of severity-of-illness (SOI) has been developed by 3 M that uses administrative discharge data coupled with the present-on-admission (POA) indicator, allowing the calculation of a SOI score both at the time of admission, and at the time of discharge. Calculation of the score is highly complex with many interactions between risk factors, but the factors most strongly relate to SOI are diagnoses that reflect physiologic impairment.
METHODS: We used linked State of California Hospital Discharge data from 20052009, to identify, for each linked record/case, the last medical hospital discharge of 3 or more days before Sept 30, 2009 and this hospitalization was used in our analysis. An in-hospital VTE event was defined using the highly specific ICD-9-CM codes 415.11 or 415.19 for pulmonary embolism (PE) and 453.41 or 453.42 for proximal and distal deep vein thrombosis in the legs (DVT) coupled with a present-on-admission (POA) indicator = No, which means the VTE developed after hospital admission. Cases were excluded if there was a VTE event within 91 days before the index admission, or if there was a surgical hospitalization within 31 days of the admission date. Severity of illness (SOI) at the time of admission was calculated using 3 M software. Other risk factors included age, race, sex, and the number of chronic comorbidities using the non-cancer terms in the Elixhauser co-morbidity index. The number of days from the index medical admission to the occurrence of VTE was modeled using multivariable Cox regression, stratifying by presence of cancer (ICD-9-CM=140209.9) or no-cancer. RESULTS: Among 1855398 cases hospitalized, 8979 cases had an inhospital VTE that met the case definition; 1742 with cancer and 7237 without. For non-cancer cases, SOI was mild in 20.2%, moderate in42.1%, major in 30.2% and extreme in 7.5%. The corresponding mean 30 day mortality rates from the day of admission were 0.9%, 3.7%,11.2% and 29.2% .VTE risk factors with a relative hazard of >2.0

included: prior VTE within 91365 days of admission, HR=2.0, (95% CI:1.7-2.5); major SOI (referent=mild) major SOI, HR=3.3, (95%CI=2.9-3.7); and extreme SOI, HR=5.0 (95%CI=4.4-5.7). For cancer cases only the SOI level was a significant predictor: for moderate SOI, HR=1.5 (95% CI: 1.0-2.1); for major SOI, HR=2.0 (95%CI=1.4-2.8); and for extreme SOI, HR=2.1 (95%CI=1.4-3.0). Seventy-two % of all in-hospital VTE cases had an SOI level that was major or extreme. The effect of SOI in predicting DVT or PE was similar, both in cancer and non cancer cases. CONCLUSION: In this observational study of medical patients hospitalized in California hospitals principally during 2008and 2009, SOI was an extremely strong predictor of development of in-hospital VTE, with a risk 5 times higher in extremely ill patients compared to mildly ill patients. Lacking any information about the use of VTE thromboprophylaxis, the findings indirectly suggest that either a high proportion of more severely ill patients do not receive thromboprophylaxis or, more likely, that the prophylaxis regimens currently used are not as effective in very sick patients. The risk of venous thromboembolism likely increases as the extent and severity of physiologic impairment increases.
TRENDS IN THE FINANCIAL BURDEN OF PRESCRIPTION DRUGS AMONG THE NON-ELDERLY, 19992007 Walid F Gellad 1; Julie M Donohue 2; Xinhua Zhao 1; Jessica S Banthin3. 1VA Pittsburgh Healthcare System/University of Pittsburgh, Pittsburgh, Pennsylvania ;
2University of Pittsburgh Graduate School of Public Health, Pittsburgh, Pennsylvania ; 3Agency for Healthcare Research and Quality (AHRQ), Rockville, Maryland . (Tracking ID # 10573)
BACKGROUND: Prescription drug expenditures and pharmacy benefit design have changed substantially over the last decade, yet little is known about the impact of these changes on the financial burden faced by consumers. We used nationally representative data to assess how the outof-pocket financial burden for

prescription drugs changed from 19992007. METHODS: We use data on individuals less than age 65 from the nationally representative Medical Expenditure Panel Survey (MEPS) to measure the financial burden for prescription drugs annually from 19992007. Following previous literature, financial burden was calculated for each individual using total out-of-pocket drug costs for all family members in a given year divided by family income. The financial burden measure was adjusted to 2007 dollars using the consumer price index and excluded premium costs. We examined the proportion of individuals living in families that spent more than 10% of their income on out-of-pocket drug costs. We analyzed how this measure of financial burden differed by insurance and income groups. Because of the potential role of increasing generic drug use on financial burden, we calculated the percentage of all prescriptions in each year that were for generic drugs.
RESULTS: In 1999, there were 7.1 million people (2.9%) who lived in families spending more than 10% of their family income on out-of-pocket costs for prescription drugs. There was a steady increase in this percentage each year until 2003, when 10.8 million individuals (4.3%) lived in families spending more than 10% of family income on drugs. From 2003 to 2007, however, the financial burden steadily decreased, and in 2007, 7.4 million individuals (2.8%) lived in families spending more than 10% of their income on drugs. Similar trends were seen in each insurance and income group, although the likelihood of high financial burden differed substantially. In 2007, 1.1% of individuals with private employer-related insurance lived in families spending more than 10% of family income on drugs, compared to 4.4% in private nongroup insurance, and 7.4% in public insurance. The financial burden for drugs was highest for the poor; 14.2% of those with income less than 100% of the poverty line lived in families spending more than 10% of their income on drugs in 2007. Between 1999 and 2003, the percentage of prescriptions filled as generics was steady between 36% to
39%, but started to increase in 2004 (40%) until in 2007, 52% of all prescriptions were filled as generics.
CONCLUSION: The financial burden for prescription drugs in those under 65 peaked in 2003 and steadily decreased from 2003 to 2007. The decrease in financial burden since 2003 is important evidence of the success of the various strategies used to lower drug costs, such as the increased use of generic drugs. This financial burden remains high, however, for low-income individuals; whether this problem will be addressed when the Medicaid expansions and insurance exchanges authorized under health reform are fully implemented is unknown. Whether rising premiums, which are not measured here, overshadow these decreasing out-of-pocket costs is also unknown.
HIV RISK AFTER RELEASE FROM PRISON: A QUALITATIVE STUDY OF FORMER INMATES Jennifer E Adams 1; Carolyn Nowels 2; Karen Corsi 2; JEREMY LONG 3; John Steiner 4; Ingrid Binswanger2. 1Denver Health, Denver, Colorado ; 2University of Colorado, Aurora, Colorado ;
3Denver Health, DENVER, Colorado ; 4Kaiser Permanente, Denver, Colorado . (Tracking ID # 10575)
BACKGROUND: Human Immunodeficiency Virus (HIV) infection and hepatitis C (HCV) are more prevalent among prison inmates than in the general population. The post-release period is a highly vulnerable time for former inmates and may be associated with increased risk behavior for these infections. Few studies have examined the health perceptions, risks and health-care seeking experiences of former inmates as they pertain to HIV and HCV, nor have they focused on the high-risk immediate post-release period. We sought to understand the experiences of former inmates during the post-release period which put them at risk for HIV or HCV transmission, acquisition, and disease progression, as well as failure to link with health care.
METHODS: This was a qualitative study of 29 former inmates 18 years and older within two months after their release from prison to the Denver, Colorado area. Trained interviewers conducted and recorded individual, in-person, semi-structured interviews exploring participants perceptions of risk, circumstances that put them at risk for HIV and HCV acquisition and transmission, and barriers to engaging in medical care after release. Interview transcripts were coded and analyzed utilizing a team-based general inductive approach to analysis. Atlas.ti software was used to code transcripts and organize data. RESULTS: Twenty men (69%) and nine women (31%) with a mean age of 39 years (range 2257 years) participated. The participants were racially and

ethnically diverse. Four major themes emerged from the interview transcripts: 1) risk behaviors, including unprotected sex, transactional sex, non-consensual sex, and drug and alcohol use, were commonly described in the immediate post-release period; 2) engagement in risky behavior often occurred within the first few days to weeks after release; 3) former inmates had important educational needs about risk behaviors as they pertained to HIV and HCV; and 4) former inmates faced major challenges in accessing health care and medications after release. Based on analysis of interview transcripts, we created a conceptual model of the multiple factors impacting rates of HIV and HCV infection, progression and transmission among former inmates (see Figure 1). CONCLUSION: Risk factors for acquiring and transmitting HIV and HCV were described as pervasive among former inmates in the immediate post-release period. Prevention efforts should be concentrated in this time period and should focus on health education, promotion of safe sex and needle practices, improved access to substance abuse treatment, and provision of safe transitional housing free of drug use. Improved coordination between correctional staff, parole officers and community health care providers may lead to improved continuity of health care and health outcomes related to HIV and HCV.

(Tracking ID # 10577)
BACKGROUND: Healthcare providers are tasked with the reconciliation of medications during care transitions. Errors may occur in this process, most commonly when documenting the pre-admission medication list (PAML) and writing discharge orders. We examined factors associated with such errors at two academic medical centers. METHODS: We analyzed data from patients assigned to the intervention arm of the Pharmacist Intervention for Low Literacy in Cardiovascular Disease (PILL-CVD) Study, a randomized controlled trial. We assessed patient characteristics associated with medication reconciliation errors including health literacy, cognitive function, and patients baseline understanding of their pre-admission medication regimen. We also determined the presence of an electronic medication list updated within 90 days prior to admission, number of pre-admission and discharge prescription medications, and number of medication changes between

admission and discharge. We used negative binomial regression to analyze predictors of the number of errors, as well as clinically-relevant errors, in the physicians PAML and discharge medication orders, considering the study pharmacists medication history as the gold standard. Results are reported as incidence rate ratios (IRR). RESULTS: Among 379 patients with admission data, 174 (41%) had at least 1 PAML error. Among 401 patients with discharge data, 158 (39%) had at least 1 error in discharge medication orders. PAML errors were more common with a higher number of pre-admission medications, and less common when a recent medication list was present (Table). Clinically-relevant discharge medication errors were associated with married status, impaired cognitive function, higher number of PAML errors, and more medication changes made prior to discharge. CONCLUSION: Medication reconciliation errors are common at the time of hospital admission and discharge. Clinically-relevant admission medication errors increased as the number of pre-admission medications increased. Furthermore, at discharge patients are at increased risk for clinically-relevant medication errors if they have impaired cognition, if PAML errors exist, or if many changes are made to their medication regimen during hospitalization. Further studies need to evaluate interventions focused on taking accurate pre-admission medication histories and verifying the accuracy of discharge orders in patients known to be at high risk for medication errors.

BARRIERS PERCEIVED BY PHYSICIANS REGARDING THEIR OWN HEALTH CARE Susan George 1; Jeffrey Jackson 2; Janice Hanson3.
1Walter Reed Army Medical Center, Washington, District of Columbia ;
2Clement J. Zablocki VA Medical Center, Milwaukee, Wisconsin ;
3Uniformed Services University of the Health Sciences, Bethesda, Maryland . (Tracking ID # 10580)

BACKGROUND: Physicians have been shown to have multiple negative health seeking behaviors, which include self prescribing and consulting friends and colleagues for their medical problems. While this type of behavior may not be harmful in acute illnesses, it is generally agreed that these behaviors can lead to poor outcomes in chronic illness and psychiatric conditions. Several studies have attempted to evaluate possible barriers to seeking care among physicians using surveys alone. This study seeks to evaluate how physicians perceive their own health care and barriers to accessing needed care through the use of semi structured interviews.

METHODS: This is a qualitative study utilizing semi structured interviews. Staff physicians and residents were recruited from the Departments of Medicine and Surgery at Walter Reed Army Medical Center and the Medical College of Wisconsin. An independent researcher performed the interviews, which focused on three major domains: perceptions about own health care, perceptions about providing care to self/family, perceptions regarding accessing mental health care. The interviews were recorded and transcribed by an outside transcription service. De-identified transcripts were coded separately by two re-
searchers for themes, with frequent meetings for discussion and disagreement resolved through discussion. This process was used to elaborate an organizational scheme with major themes. Interviews continued until no new themes emerged.

RESULTS: Saturation was achieved after 24 interviews were completed. Four major themes emerged including: 1) barriers to accessing care, 2) caring for family and friends, 3) physician health behaviors, and 4) potential solutions to barriers. Perceived barriers to care include concerns about confidentiality, fear of consequences including employability, time constraints, and stigma related to particular diseases including mental health and sexuality (function and diseases). Two beliefs emerged regarding health care for family and friends. Some physicians act as family providers or act as an intermediary, arranging care with colleagues or refilling standard medications. Other physicians made a decision not to treat family members for several reasons, including concerns about altered judgment, lack of objectivity, and guilt with potential bad outcomes. Physician health behaviors included self-diagnosing and self-prescription, informal care from colleagues, denial and minimization

of symptoms, and unhealthy lifestyles. There was a strong sense of not wanting to burden colleagues in order to take care of ones own health needs. There were many potential solutions proposed to the perceived barriers, such as building time in the schedule for regular health visits, changing the culture to improve attitudes toward stigmatized diseases and health in general, allowing physicians to receive care outside their place of work, and restricting access to electronic medical record to improve confidentiality. CONCLUSION: Physicians, both staff and residents, identified a number of important themes regarding health care for themselves and their families. There are a number of important barriers to accessing care, providers are split on providing care for family members, and physicians health behaviors are often not healthy. A number of potential solutions were suggested that could improve medical care for health care providers.

USE OF A VIDEO DECISION SUPPORT TOOL TO SUPPLEMENT GOALS-OF-CARE DISCUSSIONS WITH PATIENTS SEEN BY AN INPATIENT PALLIATIVE CARE SERVICE Nicole M. LaRue 1; MichaelK. Paasche-Orlow 1; Angelo E. Volandes2. 1Boston University Medical Center, Boston, Massachusetts; 2Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 10593)

BACKGROUND: A failure to participate in effective goals-of-care discussions may lead to the delivery of aggressive interventions in scenarios that are inconsistent with patients and families wishes. The current practice of eliciting preferences includes verbal descriptions of complex future disease states with which patients and families may have little familiarity or experience. Prior studies have demonstrated wide variability regarding patients preferences in the setting of advanced disease. The misunderstanding of factual information, particularly in patients with low health literacy, may account for a significant proportion of the variation in preferences which is observed. The use of video to reinforce verbal descriptions of treatment options may better inform patients and families engaged in end-of-life decision making. The purpose of this study is to assess the effect of a video decision support tool on preferences for end-of-life care in patients and surrogate decision makers consulted on by an inpatient palliative care service. METHODS: This temporal intervention study consists of an observational and video phase, conducted over two consecutive five month periods, or until 25 subjects are enrolled in each group. Eligible subjects include adult patients and/or their healthcare proxies who are consulted on by an inpatient palliative care team and who are

appropriate for a goals-of-care discussion. Subjects in the observational phase receive the usual standard of care provided by an inpatient palliative care service. During the intervention phase, a short video illustrating specific treatments for three different levels of medical care, i.e. life-prolonging care, basic care and comfort oriented care, is integrated into the standard palliative care consult. Following the palliative care consultation, all patient subjects and/or their healthcare proxies are surveyed regarding preferences for care near the end of life, the reasons for choosing as they did and the level of certainty regarding their decision. The primary study outcomes are the differences in proportions of patient subjects/ healthcare proxies in each group who prefer comfort oriented care and who die in accordance with their stated preferences. The secondary outcomes include the level of uncertainty regarding treatment preferences, satisfaction with pain control and symptom management and healthcare proxy satisfaction with end-of-life care following subjects death. Participants comfort level with the video is also measured. Outcomes are measured during the index hospitalization as well as over the phone at 714 days, 23 months and 56 months post-discharge.

RESULTS: To date, eight subjects have been enrolled in the observational phase of the study. When asked to identify preferences for end-of-life care, 2 preferred life-prolonging care, 1 preferred limited care, 4 preferred comfort care and 1 was unsure. The mean uncertainty score (range 0 to 50; higher score indicating greater uncertainty) was 20. There have been no adverse events reported and there has been no feedback that participation has been distressing in any way. Recruitment is actively ongoing.

CONCLUSION: The use of a video decision support tool to supplement goals-of-care discussions with patients and families consulted on by an inpatient palliative care team may provide an easily reproducible method for more accurately eliciting preferences and ultimately improve end-of-life care.

RESISTANT HYPERTENSION IN A VA POPULATION: NEED FOR FURTHER STUDY, BETTER TREATMENT AND PREVENTION OF CARDIOVASCULAR EVENT Jian Huang 1; Manmeet Singh 2; Wei Gu 1; Ronna Mallios 3; Sean McFarland 1; Jocelyn Fong1. 1VACCHCS, Fresno, California ; 2VACCHCS; UCSF Fresno, Fresno, California ; 3UCSF Fresno, Fresno, California . (Tracking ID # 10598)

BACKGROUND: Resistant hypertension (RH) is widely understudied, although it is a relatively common clinical problem with increased cardiovascular risk. The exact disease mechanisms are not well defined and the reported prevalence of RH varies with study populations. We sought to determine the prevalence of RH and its association with other co-morbid conditions in a VA population.

METHODS: Demographics and clinical data on diagnosis, labs, and medication profiles were collected from electronic records of 17,466 patients in this cross-sectional study. RH was diagnosed if BP was uncontrolled on 3 or more, or controlled on 4 or more agents, including a thiazide diuretic. We used t-test or Chi square test where appropriate for comparison of parameters between those with and without RH. We also used logistic regression model to calculate the adjusted OR and 95% CI.

RESULTS: Mean age was 67 years and BMI of 29.6 with 96% males. Overall prevalence of RH was 9% versus 13% among hypertensive patients. Patients with RH had significantly older age, higher BMI and Framingham score (FS) as well as higher prevalence of MI, PCI, CABG, CVA or TIA, PVD, CHF, ED, CKD, DM, and metabolic syndrome (MS) ($P<0.0001$). Further adjusting for confounding factors, including demographics, certain co-morbid conditions and
medications, did not change the significant association of RH with older age, higher BMI and FS, and co-existing CAD, CVA or TIA, PVD, CHF, ED, CKD, DM and MS.

CONCLUSION: Overall prevalence of RH in this study fell in the range reported in general population. Certain cardiovascular and metabolic diseases and conditions with target organ damage were significantly more prevalent in RH group. Our results suggest the need for multi-faceted intervention in this high risk population. Further research is warranted to study the underlying disease mechanisms of RH in order to develop more effective treatment for the prevention of cardiovascular event.

PERSPECTIVES OF NURSES, HOSPITALIST PHYSICIANS AND PHYSICIAN ASSISTANTS TO LOCALIZING MEDICAL TEAMS TO A NURSING UNIT: A FOCUS GROUP STUDY Siddhartha Singh 1; Kathlyn Fletcher1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 10600)

BACKGROUND: Localizing medical teams to a single nursing unit is an attractive way to organize hospital care. In our hospital we localized patients assigned to two hospitalist-physician assistant (HPA) teams on one nursing unit between the period April 1, 2010 and July 10, 2010. We studied the perspectives of nurses, hospitalist physicians and physician assistants (PA) exposed to this intervention.

METHODS: We conducted a focus group study and invited all the nurses as well as hospitalist physicians and PAs who provided patient care on the localized nursing unit to participate. Invitations were sent out by e-mail, written informed consent and demographic information was obtained from the participants. Focus groups were conducted using a semi-structured open-ended focus group guide, were audio recorded and then transcribed. All identifiers were removed from the transcriptions. We analyzed the transcribed data qualitatively using grounded theory. The process included open-coding, axial coding and selective coding. Our open-coding procedure focused on identifying the impact of localization on patients and staff. Two investigators independently coded the focus group transcripts. We began by each reviewing one focus group transcript which resulted in our coding scheme. We then used this coding scheme to analyze the remaining transcripts. Our institutional review board approved this study.

RESULTS: We conducted 4 focus groups for 29 nurses and 1 focus group for 9 hospitalist physicians and PAs

(see table). The analysis resulted in a coding scheme that mirrored the Institute of Medicines six aims for improvement of healthcare. Participants noted that patient safety increased due to greater provider accessibility, quicker responses of providers to patient decomposition and fewer telephone orders. They also felt that localized care was more effective and efficient due to functional multidisciplinary rounds and better teamwork; more patient-centered due to better and more frequent patient-provider interactions and more timely due to greater provider accessibility. On the other hand participants also noted that greater efficiency led to higher perceived workload which if not recognized and managed had the potential to have a negative impact on quality of care. Greater access of patients and nurses to providers may have the unintended consequence of more interruptions in workflow. Overall, participants felt that localization of medical teams was beneficial for patients as well as staff.
CONCLUSION: Our study is limited by being a single site study and shows that nurses, physicians and PAs felt that localization of medical teams to a single nursing unit led to improved quality of care and provider experience but the intervention had the potential for unintended negative consequences.

TALK THE WALK TO DO MORE: LOCALIZING HOSPITALIST PHYSCIAN ASSISTANT TEAMS TO A SINGLE UNIT IMPROVES WORKFLOW Siddhartha Singh 1; Vipulkumar Rana 2; Cheryl Jenks 3; Kathleen Idstein 1; David Marks1. 1Medical College of Wisconsin, Milwaukee, Wisconsin ; 2Medical College of Wisconsin, Brookfield, Wisconsin ; 3Froedtert Hospital, Milwaukee, Wisconsin . (Tracking ID # 10601)
BACKGROUND: Localization of medical teams to a hospital unit is an attractive way to organize hospitalist services but its operational impact on workflow has not been examined.
METHODS: Between April 1, 2010 and July 10, 2010, we localized patients assigned to two hospitalistphysician assistant (HPA) teams on one nursing unit. We concurrently compared the operational outcomes of these localized teams to two similar HPA teams with patients dispersed throughout the hospital to over 10 different units (the usual practice). A hospitalist faculty admitting medical officer (AMO) was asked to assign at least 5 admissions to each nonlocalized team every day. Non-localized teams did not take new patients beyond a maximum census of 16 patients each. The AMO assigned new patients to the localized teams to keep the nursing unit patient census (32) full. Beyond these guidelines the AMO was asked to consider the teams perceived workload and use judgment in deciding assignment. We collected billing information to determine total encounters for providers on these teams as a measure of clinical workload. We determined number of pages to each provider during work hours (from 7 am to 6 pm) through our telecommunication records. For the final 15 days of the intervention period we asked the Physician Assistant (PA) on each team to wear a pedometer and record steps taken during their work day as a measure of non-value added work. We used generalized estimating equations to determine the effect of localization on the number of patient encounters per day by the HPA team, number of pages during work hours to the HPA team and number of steps taken by the PAs while accounting for repeated measures per provider. This study was reviewed by the institutional review board and granted an exemption as a quality assurance project.
RESULTS: Non localized teams performed an average of 11 billable patient encounters, received 28 pages between 7 am and 6 pm and the non localized PAs took 5,554 steps during their workday. In comparison, localized HPA teams averaged 0.99 more billable patient encounters a day (CI 0.41 1.58; p=0.001) and received 11.93 fewer pages every day (CI 10.95 12.91; p<0.001). PAs on localized teams walked 1182 fewer steps during the workday (CI 215 to 2580; p=0.097). CONCLUSION: Our study shows that localizing HPA teams to one nursing unit allowed them to perform more clinical work while decreasing the number of interruptions due to pages. Fewer pages may also mean that localized HPA teams communicated more with nurses directlya safer and richer mode of communication in comparison to phone communication or orders. Additionally the pedometer data suggests that non value added work represented by number of steps walked per day may have been lower on localized

teams. In summary, localizing HPA teams to one nursing unit has a dramatically positive impact on their workflow.

OUTCOMES OF LOCALIZING HOSPITALIST-PHYSICIAN ASSISTANT TEAMS TO A NURSING UNIT

Siddhartha Singh 1; Sergey Tarima 1; Mary Conti 2; Kathlyn Fletcher 1; Vipulkumar rana 3; David Marks1. 1Medical College of Wisconsin, Milwaukee, Wisconsin ; 2Froedtert Hospital, Milwaukee, Wisconsin ; 3Medical College of Wisconsin, Brookfield, Wisconsin . (Tracking ID # 10605)

BACKGROUND: Localization of medical teams to a hospital unit has been shown to improve nurse-provider communication but its affect on patient outcomes is unknown.

METHODS: Between April 1, 2010 and July 10, 2010 we conducted a trial of localizing patients assigned to two hospitalist-physician assistant (HPA) teams to one nursing unit. We concurrently compared their outcomes to patients assigned to two similar HPA teams with patients dispersed throughout the hospital to over 10 different units (the usual practice). Patients with a principal diagnosis of sickle cell disease (SSD) were excluded from the analysis as they were preferentially assigned only to the non-localized teams. A faculty admitting medical officer (AMO) assigned patients to each team and did not use any clinical criteria (other than diagnosis of SSD) to make this assignment. The AMO was asked to assign at least 5 admissions to each non-localized team every day. Non-localized teams did not take new patients beyond a maximum census of 16 patients each. The AMO assigned new patients to the localized teams to keep the nursing unit patient census (32) full. Beyond these guidelines the AMO was asked to consider the teams perceived workload and use judgment in deciding assignment. We used linear mixed models for comparing log-transformed length of stay and charges, and generalized linear mixed models for comparing 30 day risk of readmission. We controlled for age, race, gender, payer status, weekend admission/discharge, co-morbidities, principal diagnosis and the effect of repeat admissions of the same patient. This study was reviewed by the institutional review board and granted an exemption as a quality assurance project.

RESULTS: 655 admissions were assigned to the localized teams and 541 (non-sickle cell) admissions were assigned to the non-localized teams. These admissions were similar except that patients on localized teams were older. As compared with patients cared for by non-localized teams, patients cared for by localized teams had a 11% longer adjusted length of stay (P=0.022) but similar charges and similar 30-day risk of readmission (see table).

CONCLUSION: Our study reveals a counterintuitive finding of higher length of stay when we localized HPA teams- an intervention designed to promote efficiency. This finding needs to be further explored within a wider context of other measures of quality of care such as patient satisfaction, failure to rescue rates and process measures. In addition, as new patients could be assigned to the localized teams only when the nursing unit had open beds due to discharges, there may have been a perverse incentive promoting higher length of stay to keep unit census high.

POLST USE IN CALIFORNIA NURSING HOMES

Neil S Wenger 1; Mimi Tarn 2; Allison Diamant 1; Karl Lorenz 3; Judy Citko 4; Kate OMalley5. 1UCLA GIM&HSR, Los Angeles, California ; 2UCLA Department of Family Medicine, Los Angeles, California ; 3Greater Los Angeles VA Medical Center, Los Angeles, California ; 4Coalition for Compassionate Care of California, Sacramento, California ; 5California HealthCare Foundation, Oakland, California . (Tracking ID # 10607)

BACKGROUND: Physicians Orders for Life Sustaining Treatment (POLST) forms improve communication of life-sustaining treatment preferences across care venues. California implemented this clinical tool in 2009 and a novel intervention of Community Coalitions was undertaken to advance POLST in localities. Community Coalitions engaged local hospitals, emergency services providers and nursing homes in educational and

operational activities designed to support POLST adoption. About 18 months after introduction of POLST, we studied the implementation of POLST in California nursing homes (NHs) and the association with Community Coalition activity.
METHODS: NHs randomly selected in Coalition and non-Coalition counties were mailed surveys asking about POLST use and problems with implementation. Coalitions identified with which NHs they worked and the level of intensity of interaction with each NH.
RESULTS: Of 547 NHs surveyed, 143 (51%) of those in Coalition counties participated and 141 (52%) from non-Coalition counties. At 83% of responding NHs at least some staff had received POLST education and 59% of NHs reporting having a formal policy on handling POLST. Two-thirds of NHs had admitted a resident with a POLST and approximately 23% of newly admitted residents over the past month had a POLST (range 0-100%) (Coalition county NHs 26% v non-Coalition county NHs 19%, p=0.2). Eighty percent of NHs had completed a POLST with a resident and 55% of residents were estimated to have a POLST (range 0-100%) (Coalition county NHs 61% v non-Coalition area NHs 50%, p=0.04). NHs receiving more intense Coalition interaction had a greater percentage of staff with education, were more likely to have a POLST champion, and were more likely to have completed a POLST with a resident after admission (no interaction 76%, low intensity 87%, high intensity 95%, p<0.01). Few NHs (7%) reported difficulty following POLST orders, but 37% noted difficulty involving physicians in POLST completion and 62% reported difficulty in obtaining original POLST documents from other facilities.
CONCLUSION: Less than 2 years after introduction, most California nursing homes report using POLST, although some NHs reported no
experience. A novel Community Coalition intervention facilitated POLST implementation.
EMPATHY, SUPPORT, OR BLAME REGARDING CIGARETTE SMOKING FROM PHYSICIANS CARING FOR TERMINAL LUNG CANCER PATIENTS: WHEN YOU STARTED, EVERYONE SMOKED AND IT WAS COOL
Diane S Morse 1; Elizabeth A Edwardsen 2; Shmuel Reis 3; Sally J Rousseau 4; Mary Gale Gurnsey 5; Adam Taupin 6; Cleveland G Shields 7; Jennifer J Griggs 8; Susan H McDaniel9. 1University of Rochester School of Medicine, Rochester, New York ; 2Departments of Emergency Medicine and Medicine, University of Rochester School of Medicine, Rochester, New York ;

(Tracking ID # 10608)
BACKGROUND: Patient-centered care is respectful of and responsive to individual patient needs and beneficial for numerous patient outcomes. Patients with advanced cancer are especially in need of compassionate, caring physician responses. However, patient morbidity and mortality concerns can be particularly difficult for physicians to address. These health conditions can engender complex dialogues, making them fruitful for study of communication strategies. One issue of clinical importance in lung cancer care is how physicians address patients potential emotional reactions regarding any history of their cigarette smoking, since it is a frequent mediating factor in the disease. Other studies, with conditions including lung and breast cancer, as well as rape and HIV infection, have found an association between a lack of supportive communication, blaming, and

shaming from medical providers and worsened outcomes. Successful motivational behavior change strategies employ support and empathy. Because supportive communication is associated with better outcomes, it is important to understand

dialogues between lung cancer patients and physicians in regard to cigarette smoking. The objective of this study is to examine physician communication associated with cigarette smoking in an existing database of first visits of undetected standardized patients (SPs) with stage IV lung cancer.
METHODS: Design: Consenting physicians had covert audio recordings of office visits with SPs. Population: Practicing physicians: 23 community oncologists and 23 community family physicians of which SPs successfully audio-recorded 19 oncologists and 20 family physicians. Physicians averaged 48.1 (SD=9.2) years old. Seventy-one percent were male and 29% were female. Prompted physicians were able to identify the SP correctly in 15% (n=5) of visits which were subsequently removed from the data set, leaving 34 undetected visits for this study. Analysis and text management: We conducted a thematic analysis of the transcripts, using an iterative process to create a coding system, with keywords and phrases in areas of interest. Two team researchers, randomly paired, coded each transcript. Coding development continued until saturation; with each revision all previously coded interviews were recoded by a minimum of 2 researchers. We resolved differences in coding in the larger research group by consensus. Team members then reviewed all coded elements in context, using sequence analysis to understand cigarette smoking dialogue, focusing on physician speech. Identifying and defining cigarette smoking-related dialogue: Dialogue categories consisted of a) patient cigarette smoking related cues with physician responses and b) physician spontaneous questions regarding smoking behavior. We categorized these dialogues as supportive or not supportive by the physician towards the patient. Supportive statements regarding smoking were affirming, empathic, or non-blaming towards the patients decision to smoke or having cancer. Not supportive statements regarding smoking occurred either as a nonempathic response to an SP empathic cue or were blaming towards the patient for smoking or having cancer.
RESULTS: Actor adherence to role averaged 92%. Twenty six of the 34 (76.5%) encounters contained a total of 49 dialogues regarding cigarette smoking, with a range of 04 smoking dialogues per encounter. Of these dialogues, 14.3% (n=7) were found to be supportive and 85.7% (n=42) were unsupportive. Supportive dialogues included empathy regarding the patients decision to smoke (The sad thing is that people who smoke and develop a condition they blame themselves -they feel guilty. People from your generation were fooled. When you started, everyone smoked and it was cool.) and acknowledged the difficulty of quitting (Its tough isnt it?). Unsupportive dialogues included pairing delivery of a poor prognosis with a statement about patient smoking (Nowadays most people with lung cancer are previously smokers.), responding to family history of death from lung cancer with a statement about smoking rather than empathy (Patient: My mother died of lung cancer. Doctor: Was she a smoker?), and not acknowledging the difficulty of quitting smoking (Youve been smoking a lot off and on.).
CONCLUSION: Lung cancer patients frequently have a history of cigarette smoking which has contributed to their disease. It is to be expected that they feel some shame, guilt, sadness, or regret regarding their decision to smoke. Physicians can respond supportively by empathically acknowledging reasons patients may have started smoking and the difficulty of quitting. Less supportive responses include linking diagnostic or prognostic statements with the smoking history, which may be interpreted by the patient as blame for the disease. When a patient has a family history of lung cancer, concerns can be similarly addressed in a supportive fashion. Physicians can empower patients to address a personal and family legacy of smoking therapeutically through supportive
behaviors. Cigarette smoking histories present an under-addressed opportunity for physicians to provide support and avoid blaming lung cancer patients. Such supportive relationships, in other health related domains

have been associated with improved outcomes.
BARRIERS TO A COMMUNITY-BASED HEALTH INFORMATION EXCHANGE OF MENTAL-HEALTH DATA TO SUPPORT PRIMARY CARE Michael Weiner 1; Paul Dexter 2; Donald P. Hay 3; Donald Lindgren 4; Faye Smith 5; Tull Glazener 5; Adriane E. Siefert 5; Kristyn Looney 5; Klaus Hilgarth 3; Malaz Boustani 6; Hugh Hendrie 10; Christopher Callahan10. 1Indiana University Center for Health Services and Outcomes Research, and Center of Excellence on Implementing Evidence-Based Practice, Department of Veterans Affairs, Veterans Health Administration, Health Services Research and Development Service HFP 04148, Indianapolis, Indiana ; 2Wishard Health Services and Regenstrief Institute, Inc., Indianapolis, Indiana ; 3Indiana University School of Medicine, Indianapolis, Indiana ; 4Midtown Community Mental Health Center, Indianapolis, Indiana ; 5Regenstrief Institute, Inc., Indianapolis, Indiana ; 6Indiana University Center for Aging Research, Indianapolis, Indiana . (Tracking ID # 10609)
BACKGROUND: Although excellent primary care requires comprehensiveness and coordination, many patients see primary care providers with limited access to specialty-care records. Mental-health (MH) records are often sequestered due to historical practices or policies. In health information exchange (HIE), institutions create agreements and technical means to share selected information. Exchanging certain MH information poses challenges, because federal and State law restricts sharing of details about substance abuse. With attention to policy, law, and technology, we integrated into an electronic health record (EHR) system the diagnoses of patients also seen in an affiliated community MH center (CMHC).
METHODS: The CMHC uses an electronic data system at all of its 13 sites. Stakeholders were gathered, including institutional leaders, their attorneys, and technical staff from the EHR vendors. The team reviewed legislation, institutional practices for managing and protecting data, and technical requirements for transmitting, storing, and displaying data. Agreements were reached to enable the HIE to occur. Due to disparities in designs of the EHR systems, CMHC records were examined to determine technical structure and relationship to native entry of data such as diagnoses. Data were imported into the primary, comprehensive EHR system, which includes all order entry, diagnostic test results, inpatient and outpatient narrative notes, and imaging and is accessed more than ten million times per year at the local institution. This EHR system is part of a city-wide HIE with five hospital systems, including 11 hospital facilities and more than 100 clinics and day surgery facilities. Following inspection of data, clinicians were informed about availability of CMHC data in the primary EHR system. RESULTS: The CMHC provides care for about 1700 patients who are also seen in primary care. Regarding substance-abuse records specifically, the Code of Federal Regulations (Title 42, Part 2) prohibits disclosure without a patients consent. One exception allows for disclosure between or among personnel having a need for the information in connection with the diagnosis or treatment if the communications are within a program or between a program and an entity having direct administrative control over the program. More broadly regarding MH data other than psychotherapy notes, the Health Insurance Portability and Accountability Act does not treat such data

differently from medical or surgical data, which can be shared for treatment. Under the authors State law, exchanging MH data between providers within an institution is also permitted. The institutions ongoing participation in the city-wide HIE program complicated plans to share new data. Limiting HIE of CMHC data to the primary institution and the CMHC required these data to be electronically tagged and required new access controls. Transferring data from the CMHC EHR required agreement upon data formats and telecommunications technologies. Making the CMHC data available in the main EHR system also required creating a new template through which data could be displayed. CMHC data including diagnoses were delivered to the primary system. The main user interface was modified to include a link to the CMHC information, enabling

primary care providers to access CMHC data. Next steps include incorporating into the main EHR system the narrative progress notes from the CMHC.
CONCLUSION: This work illustrates legal, cultural, and technical issues surrounding sharing of community-based MH data to support primary care. Adding MH data to an existing HIE requires attention to law, local access controls, data formats, and education of administrators and clinicians.
HOW DO PATIENTS AND PHYSICIANS DIFFER IN THEIR CONCEPTUALIZATION OF THE REASON FOR HOSPITALIZATION? Zackary Berger 1; Anne Dembitzer 2; Mary Catherine Beach1. 1Johns Hopkins School of Medicine, Baltimore, Maryland; 2NYU School of Medicine, New York, New York. (Tracking ID # 10610)
BACKGROUND: An emerging body of literature focuses on concordance between patient and physician in terms of understanding of reasons for hospitalization. This basic agreement - or common ground - forms the very basis by which all other communication regarding an illness and its treatment is based. The few existing studies that exist on this topic vary widely in their estimates of diagnostic concordance. In light of the potential differences among studies in the measurement of diagnostic concordance, and to address patient understanding of hospitalization in general, we sought to qualitatively analyze the ways in which stated reasons for hospitalization differ between patient and physician from an epistemological perspective, in order to develop a framework for understanding inpatient-physician diagnostic discordance. An emerging body of literature focuses on concordance between patient and physician in terms of understanding of reasons for hospitalization. This basic agreementor common groundforms the very basis by which all other communication regarding an illness and its treatment is based. The few existing studies that exist on this topic vary widely in their estimates of diagnostic concordance. In light of the potential differences among studies in the measurement of diagnostic concordance, and to address patient understanding of hospitalization in general, we sought to qualitatively analyze the ways in which stated reasons for hospitalization differ between patient and physician from an epistemological perspective, in order to develop a framework for understanding inpatient-physician diagnostic discordance.
METHODS: In a major urban medical center in New York, we asked inpatients whether they knew why their doctors admitted them to the hospital, comparing that to their most recent physicians note in the medical record. We then qualitatively analyzed statements made by patients and physicians regarding reasons for admission, classified ways in which these statements differed, calculated the prevalence of diagnostic concordance, and developed a model to demonstrate its potential impact on communication.
RESULTS: Of 46 patients, diagnostic concordance was present in 25 (54%), discordance in 16 (35%), and 5 patients (11%) could not give any reason for their hospitalization. Both patients and physicians most often expressed the reason for hospitalization in terms of diagnosis (kidney stone) rather than symptoms (back pain). Patients whose statements were concordant with their providers usually used slightly different terminology; some also included or omitted detail found in the physicians statements. Patients whose statements were discordant with their physicians were either vague (Im sick), agreed on organ system (chest pain vs. dysphagia), or disagreed on the organ system involved (cant speak vs. atrial tachycardia).
CONCLUSION: A significant proportion of medicine inpatients could not state their physicians reason for admission. Further research on this topic should investigate whether establishing inpatient diagnostic concordance improves outcomes.
RESIDENT USE OF SMARTPHONES WHILE PROVIDING PATIENT CARE Mitesh Patel 1; Jessica Dine 1; David Asch1. 1Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania. (Tracking ID # 10615)
BACKGROUND: The use of smartphones among the general population has grown dramatically over the past decade. The growth of medical applications for these devices has helped stimulate their adoption as a new tool for health care providers. Yet, their use by physicians in clinical settings is unknown.
METHODS: Our objective was to determine the percentage of internal medicine residents using smartphones in clinical settings, to assess how the devices were being used, and to evaluate perceptions of the impact of

smartphone use on patient care. We surveyed internal medicine housestaff at three academic medical centers (Brigham and Womens Hospital, the Hospital of the University of Pennsylvania, and the University of California, San Diego) between December 2009 and February 2010. Surveys were administered as hardcopies at intern and resident conferences, as well as through an online version that was made available through email.
RESULTS: Among 125 respondents, 79 (63.2%) used a smartphone as a tool while providing patient care (TABLE 1). The most commonly used device was the iPhone and iTouch (64.6%), followed by the Blackberry(12.7%). Among smartphone users, about two-thirds used their device at least four times a day as an aid for providing patient care. The most common use of the smartphone was for medication reference (96.2%) or as a medical calculator (89.9%). More rare uses included using the camera feature to evaluate at rash over time, viewing pill identification photos for medication reconciliation, and searching the internet for journal articles and other medical information. Smartphones were perceived by housestaff to help save time (93.5%), reduce medication errors (77.9%) and improve quality of care (68.8%). A higher proportion of interns indicated that a smartphone helped them with specific tasks such as learning more medicine, choosing treatment options, improving patient safety and reducing medication errors. In contrast, a higher proportion of residents felt a smartphone helped them with broader issues, such as reducing healthcare costs and improving quality of care. Qualitative analysis revealed that use of smartphones while providing patient care created risks to patient privacy, the patient-physician relationship, and conflicts of interest in medical decision-making (TABLE 2). In contrast, benefits included enhanced ability to perform medication reconciliation and practice medicine at the point-of-care. More than half of respondents that did not use a smartphone reported that it was due to financial reasons. .
S104 ABSTRACTS JGIM
CONCLUSION: A significant proportion of residents are using smart-phones as a tool for providing patient care. These smartphones may play
an important role on improving physician efficiency, patient outcomes and health care quality.

Patient privacy
- New challenges to protecting patient privacy- Lack of standard guidelines for storing patient information or taking pictures- Password protection has not been universally adopted
- Hospital and health institutions should evaluate systematic methods that can be implemented to reduce breaches in patient privacy through wireless and cellular technology such as virtual private networks (VPN), secure sockets layer (SSL), and encryption techniques <p class="Ms
THE DIFFERENTIAL EFFECT OF HOSPITAL SERVICE-LINE PROFITABILITY ON READMISSIONS VERSUS

DEATH Amol S. Navathe 1;
Kevin G. Volpp 1; R. Tamara Konetzka 2; Matthew J. Press 3; Jingsan Zhu 1; Richard C. Lindrooth4. 1University of Pennsylvania, Philadelphia, Pennsylvania ; 2University of Chicago, Chicago, Illinois ; 3Cornell University, New York, New York ; 4University of Colorado Denver, Denver, Colorado . (Tracking ID # 10618)
BACKGROUND: Recent policy reform has emphasized the role of readmission rates as an indicator of quality of care, particularly with linking reduced Medicare payments to excess readmissions in The Patient Protection and Affordable Care Act. Under prospective payment, a reduction in reimbursement rates can potentially lower the quality of care during the hospital stay. We examine two measures that are commonly associated with the quality of hospital care: 30-day read-missions and 30-day mortality. Our objective was to determine whether the profitability of hospital service-lines to which a patient was admitted
was associated with the likelihood of readmission or death within 30 days.
METHODS: We utilized a two-stage Cox proportional hazards competing risks framework, allowing for the simultaneity of readmission and mortality risks in the post-hospitalization period. This analysis was performed on a sample of 15,731,768 Medicare Fee-for-Service (FFS) discharges from 4,815 general acute-care hospitals eligible for prospective payment (PPS) during the fiscal years 1997, 2001, and 2005. Risk adjustment was performed using Elixhauser comorbidities and year fixed-effects controlled for secular trends. Baseline hazards were computed at the hospital service-line level to focus on longitudinal within-hospital variation. Profitability was measured using annual markup, computed by subtracting the cost of stays from the allowed charges and dividing this difference by the cost.
RESULTS: There was no evidence of an association between service line profitability and readmission risk (average effect: 0.16 percentage point decrease in readmission risk per 10 percent increase in markup, p-value

range less than 0.001 to 0.092). This effect was most pronounced for hospitals with high shares of Medicare patients, with an average magnitude of 1.67 percentage points per 10 percent increase in markup (p-value less than 0.001). As the service-line markup approached break-even, sensitivity to changes in markup increased.
CONCLUSION: Service-line profitability impacted readmission and death within 30 days of discharge differentially, with no effect on the rate of readmission and a negative relationship with mortality. This finding highlights the complexity in utilizing readmission rates as quality of care indicators. Thirty day mortality has been implemented by CMS as an indicator of inpatient quality for certain conditions. However, there is still controversy regarding the use of 30-day readmission rates. On the one hand rapid readmissions may reflect poor quality of inpatient care. On the other hand, readmissions may also reflect the post-discharge quality of care, including transitions to the outpatient setting and outpatient care itself. The quality of care post-discharge may be unaffected by the variation in inpatient profitability and, as a result, readmission rates were unaffected. While post-discharge care likely also plays a role in 30-day mortality, our findings suggest that it did not offset the effect of reduced inpatient profitability.
CAN WE MEASURE AGENDA SETTING AND BALANCING PRIORITIES IN ENCOUNTERS AND ARE THESE SKILLS INDEPENDENT? Sondra Zabar 1; Kathleen Hanley 1; Jennifer Adams 1; Mack Lipkin 1; Colleen Gillespie2. 1NYU School of Medicine, New York, New York; 2NYU School of Medicine, NY, New York. (Tracking ID # 10619)
BACKGROUND: Agenda-setting and prioritizing are critical skills for effective and efficient clinical care. Studies have shown that physicians commonly interrupt patients early into the interview and do not fully uncover patients agendas. While some communication skills curricula emphasize surveying problems to elicit concerns, there is less focus on skills related to agenda setting. Little is known about how agenda setting influences the rest of the clinical encounter. To examine these processes we created an Objective Structured Clinical Exam

Station where the learner needs to uncover and manage an urgent, unanticipated agenda. METHODS: 21 PGY1, 2 &3 medicine residents completed an OSCE station as part of an annual 10-station OSCE in which a 63-year-old healthy male presented worried about the flu and receiving the H1N1vaccination. If he was asked if he had other concerns, he showed a mole to the doctor. The mole was a realistic (validated by dermatologists) melanoma tattoo. For each OSCE station including this one, trained Standardized Patients (SPs) rated residents communication, organization and time management, assessment, patient education and counseling, and management and treatment plan performance across cases using a 19-item behaviorally anchored checklist with 3 response options (not done, partly done, well done). Cronbachs alpha ranged from .68 to .90 for items within these skill domains. Scores were calculated as % of items within each category rated as well done. In addition to assessing these general skills, the SP also indicated whether he had a chance to express both H1N1 and mole concerns at the start of the visit and whether the resident prioritized one or the other, balanced both issues, or prioritizing was unclear. Chi Square analyses explored whether this measure of agenda-setting/prioritizing was associated with residents performance in the other cases. Independent samples t-tests were used to assess whether residents ability to set the agenda/prioritize in this case was associated with mean differences in overall OSCE performance in core domains. RESULTS: Overall 86% (18/21) residents recognized the urgency of evaluation of the mole. 17/21 (81%) of residents gave the SP an opportunity to express both concerns at the start of the visit. 2 residents prioritized either H1N1 or the mole (10%), 12 residents achieved a balance between the two (57%), and 7 residents priorities were unclear (33%). Residents who
established balanced priority between the patients two concerns performed better than the other residents in 2 of the 3 assessment items: agenda-setting (p=.06) and history gathering for the skin lesion (p=.01) but not in exploring the patients anxiety (p=.44). These residents did not perform better in the 2 education and counseling items focused on H1N1 but they did in providing recommendations for the skin lesion (p=.07). They also performed better than residents who either didnt set a clear priority or who clearly prioritized one over the other in management and establishing a treatment plan: 100% discussed next steps vs. 71% and 50% respectively (p=.03) and 100% made a specific plan for follow-up vs. 0% and 50% respectively (p<.001). OSCE results from the other 9 stations mirrored those found in this station: residents who had balanced the priority of the patients two concerns received higher assessment and management/treatment plan scores across the ten stations OSCE than those in the other two groups combined (assessment: mean of 55% well done vs. 36%, p=.046; management/treatment plan: mean of 53% well done vs. 42%, p=.027). Residents communication and patient education and counseling scores did not differ. CONCLUSION: An OSCE station using a mole tattoo effectively demonstrated a relationship between agenda setting and balancing priorities. Balancing priorities and setting the agenda appears to be a skill largely independent of communication and patient education skills. However, this skill appears to be associated with effectively assessing patient health concerns and arriving at and effectively recommending an appropriate management/treatment plan. This advanced communication skill set incorporates clinical reasoning and negotiations and may prove to be a key communication skill.

FINANCIAL CONDITION OF TEACHING HOSPITALS AND PATIENT OUTCOMES FOLLOWING 2003 ACGME RESIDENT DUTY HOUR REFORM Amol S. Navathe 1; Jeffrey H. Silber 2; Amy K. Rosen 3; DylanS. Small 1; Yanli Wang 2; Jingsan Zhu 1; Michael Halenar 1; Kevin G. Volpp1. 1University of Pennsylvania, Philadelphia, Pennsylvania ; 2The Childrens Hospital of Philadelphia, Philadelphia, Pennsylvania ; 3Boston University, Boston, Massachusetts . (Tracking ID # 10630)

BACKGROUND: The new Accreditation Council for Graduate Medical Education (ACGME) revised resident duty hour regulations will take effect July 1, 2011. One of the concerns is that these duty hour rules represent a significant unfunded mandate, with estimated costs of several hundred million dollars per year. The differential impact of duty hour reform on patient outcomes by underlying financial health of teaching hospitals is unknown. Hospitals that are more financially stressed may be less able to respond to such mandates and as a

consequence, patient outcomes may be affected. In this study, we examine whether hospital financial health was associated with differential outcomes before and after implementation of the 2003 ACGME duty hour regulations.
METHODS: We used 20002005 Medicare data to evaluate changes in a comprehensive set of patient outcomes in less versus more financially healthy hospitals before and after duty hour reform. Financial health of hospitals was measured as the average ratio of cash flow to total revenue in the year prior to duty reform implementation using Medicare Cost Reports data. Interrupted time series analysis and logistic regression models, adjusting for patient comorbidities, common time trends, and hospital site, were utilized to assess changes over time. Outcome measures included mortality within 30 days of hospital admission, AHRQ Patient Safety Indicators (PSIs), failure-to-rescue (FTR) rates, and prolonged length of stay (PLOS). PSI measures included PSIC reflecting continuity of care in the perioperative setting, PSI-T representing technical skills-based care, and PSI-O, an Other composite, with a mix of surgical and medical PSIs. We studied 3,614,174 unique Medicare patients admitted to 869 short-term acute-care non-federal teaching hospitals with principal diagnoses of acute myocardial infarction (AMI), congestive heart

failure (CHF), gastrointestinal bleeding, or stroke or a DRG classification of general, orthopedic or vascular surgery.
RESULTS: There was no systematic evidence that the degree of change in patient outcomes was associated with hospital financial health in post-reform year 1 (Post 1) or year 2 (Post 2) versus the pre-reform period. All 8 tests measuring the association between mortality and hospital financial health quartile were insignificant: Post 1 OR range 1.001.02 (95% CI range, 0.971.04) and Post 2 OR range 0.991.02 (0.971.05). For PSIs, 6 of 8 tests were insignificant except for minor effects in Post 1 for PSI-O and Post 2 for PSI-T: OR 0.96 (0.940.99) and OR 0.97 (0.940.99) respectively. FTR rate analysis demonstrated no significance for either post-reform year (OR 1.00 for both) and the test on PLOS outcomes resulted in significance only for the combined surgical sample in Post 2: OR 1.03 (1.021.04). CONCLUSION: Hospital financial health was not associated with differential changes in patient outcomes before or after the 2003 ACGME duty hour reform. Our findings offer evidence that despite the significant costs, financially stressed hospitals kept up with the financially healthiest hospitals in quality of care provided. If we had found a deleterious association, then newly anticipated financial stresses from more stringent 2011 duty hour rules would have been cause for very serious concern. As it stands, our results provide some reassurance that teaching hospitals may successfully adapt to these new financial pressures without significant reductions in quality.
ELECTRONIC RISK ALERTS TO IMPROVE PRIMARY CARE MANAGEMENT OF CHEST PAIN: A RANDOMIZED, CONTROLLED TRIAL Thomas Sequist 1; Shane Morong 1; Amy Marston 2; Carol Keohane 1; E. Francis Cook 1; E. John Orav 1; Thomas Lee1. 1Brigham and Womens Hospital, Boston, Massachusetts; 2Harvard Vanguard Medical Associates, Boston, Massachusetts. (Tracking ID # 10631)
BACKGROUND: The primary care evaluation of chest pain represents a significant challenge. Electronic decision support could improve the quality and safety of chest pain evaluations by promoting risk-appropriate care. METHODS: We enrolled 292 primary care clinicians caring for 7,083 adult patients with chest pain and no history of cardiovascular disease across 15 health centers. Clinicians were randomized to receive alerts within the electronic health record recommending risk-appropriate care based on automated calculation of the Framingham Risk Score (FRS) during office visits for chest pain. One alert recommended performance of an electrocardiogram and administration of aspirin for high risk patients (FRS greater than or equal to 10%), and a second alert recommended against performance of cardiac stress testing for low risk patients (FRS <10%). The primary outcomes included performance of an electrocardiogram and administration of aspirin therapy for high risk patients during the office visit; and avoidance of cardiac stress testing within 2 months of the office visit for low risk patients. Hospital outcomes were collected within 1 month of the office visit. We surveyed all 292

clinicians enrolled in the study at the conclusion of the 15 month intervention period, achieving a 76% response rate.
RESULTS: The majority (81%) of patients with chest pain were classified as low risk. The clinical evaluation was generally more aggressive among high risk patients compared to low risk patients, including rates of performing electrocardiograms (50% versus 43%, p<0.001) and cardiac stress tests (17% versus 10%, p<0.001). High risk patients were more likely than low risk patients to be evaluated in the emergency department (11% versus 5%, p<0.001) and to be hospitalized (7% versus 3%, p<0.001). A diagnosis of coronary artery disease was established more commonly among high risk compared to low risk patients (1.1% versus 0.5%, p<0.001). Acute myocardial infarction occurred among 28 (0.4%) patients, also more commonly among high risk compared to low risk patients (1.1% versus0.2%, p<0.001). Among 28 diagnoses of acute myocardial infarction, 10 (36%) represented missed diagnoses in the primary care setting not referred to the emergency department for acute management. Among high risk patients, there was no difference between the intervention and control groups in rates of performing electrocardiograms (51% versus 48%, p=0.33) or administering aspirin (20% versus 18%, p=0.43). Among low risk patients, there was no difference between intervention and control groups in rates of cardiac stress testing (10% versus 9%, p=0.40). A majority of intervention clinicians felt that the electronic alerts for high risk patients were very (9%) or somewhat (49%) effective at improving their management of chest pain. A large majority of clinicians (81%) felt that the cut-off of 10% for the FRS to identify high risk patients was about right. CONCLUSION: Acute myocardial infarction is infrequent among primary care patients with chest pain, though often misdiagnosed. Primary care management of chest pain commonly involves underutilization of interventions in high risk patients and overutilization in low risk patients. Electronic alerts do not increase risk-appropriate care for these patients.
PATIENT-PROVIDER RACE CONCORDANCE AND ADHERENCE TO ANTIHYPERTENSIVE MEDICATIONS: WHAT IS THE ROLE OF PATIENT TRUST? Antoinette Schoenthaler 1; Linda Baier Manwell 2; Mark Linzer 3; Roger Brown 2; Mark Schwartz1. 1NYU School of Medicine, New York, New York ; 2University of Wisconsin, Madison, Wisconsin ; 3Hennepin County Medical Center, Minneapolis, Minnesota . (Tracking ID # 10655)
BACKGROUND: Perceived quality of the patient-provider relationship has emerged as a potential contributing factor to racial disparities in healthcare. Race-discordant patient-provider relationships have been linked to lower perceived quality of care among Black patients receiving care from White providers compared to Black patients in race-concordant relationships. Alternatively, patients in race-concordant relationships have longer medical visits with higher ratings of positive affect, shared-decision making, and satisfaction. Despite mounting evidence that patient-provider race concordance affects processes of care (e.g., patient satisfaction, health service utilization), the impact on intermediate patient outcomes such as medication adherence is unclear. More importantly, no study has examined the mechanisms by which race concordance affects patient outcomes.
METHODS: We analyzed cross-sectional data from surveys of primary care providers and their hypertensive patients participating in the Minimizing Error, Maximizing Outcome (MEMO) Study, a multi-method longitudinal (20012005) study designed to explore the relationships between work conditions, physician outcomes and quality of care. Race concordance was characterized as dyads where both the patient and provider were of the same race; race discordance was characterized as dyads where the patient was Black and the provider was White. Medication adherence was assessed by asking patients to respond to a single question: In a typical week, how close do you come to following your doctors recommendations about medications? Responses were dichotomized as always take all of my medicine vs. usually/ sometimes take all of my medicine. Patient trust was measured with 4-items assessing the patients overall trust in the provider as well as trust in their providers medical decision-making under certain financial/administrative constraints. Responses ranged from not at all to completely on a 5-point Likert-type scale. Multivariate logistic regression models tested the hypothesis that a higher proportion of patients in race-concordant dyads would exhibit better medication adherence than patients in the race-discordant dyads, after adjusting for patient (e.g., gender, age, number of hypertensive medications),

provider (e.g., age, gender, specialty), and clinic-level (e.g., location) characteristics. Using Mackinnons model of mediation analysis, probit regression models were conducted to assess the effect of race concordance on medication adherence and if trust mediated this relationship.
RESULTS: Data from 220 physicians (10% Black, 41% female; mean age 44) and 816 of their hypertensive patients (24% Black, 64% female;

mean age 61) were included. Eighty-seven percent (87%) of patients were in race-concordant relationships: 76% in a White patient-provider dyad and 11% in a Black patient-provider dyad. A total of 55% of Black patients were in race-discordant relationships with White providers compared to only 1% of White patients seen by Black providers; we excluded the latter group due to the small sample size. White patients were older and had more comorbid conditions and lower diastolic blood pressure than Black patients in either race-concordant or discordant relationships (p=0.05 for each) and race-discordant relationships (69%; OR=0.51, 95% CI 0.30, 0.84, p=0.008). Adherence levels were not significantly different among Black patients in race-concordant vs. race-discordant relationships (p >0.05). Trust in the provider did not mediate the effect of race concordance on medication adherence; rather it had an independent effect. For each 1-point increase in the trust scale, all patients were 1.8 times more likely to report always being always adherent to their medications, irrespective of their providers race (OR=1.82, 95% CI: 1.30-2.55, p<0.001). CONCLUSION: White patients with White providers reported the highest levels of adherence. Among Black patients, there were no significant differences in adherence levels by racial composition of the patient-provider relationship. Trust in ones provider was associated with better adherence for all patients, regardless of racial composition of the patient-provider relationship. While these findings do not conform to previous studys results, they convey an important message to the medical field. A patient-provider relationship characterized by high levels of trust is an influential determinant of patient behavior and even transcends the influence of race in certain populations. Future research is needed to understand under what circumstances race-concordance affects intermediate patient outcomes, particularly in Black patients, and the mechanisms driving this relationship.
BIOMARKERS FROM MULTIPLE PATHWAYS ARE NOT ASSOCIATED WITH THE ONSET OF TYPE 2 DIABETES: THE FRAMINGHAM HEART STUDY. Dhayana Dallmeier 1; Martin Larson 2; Na Wang 3; Joao Fontes 2; Emelia Benjamin 2; Caroline Fox2. 1Boston University Medical Center, Boston, Massachusetts; 2Framingham Heart Study, Framingham, Massachusetts; 3Boston University School of Public Health, Boston, Massachusetts . (Tracking ID # 10659)
BACKGROUND: Prior studies report conflicting findings regarding the association of biomarkers in predicting the onset of type 2 diabetes. We evaluated a panel of 12 biomarkers as possible predictors of the new-onset of diabetes in the Framingham Heart Study.
METHODS: We measured levels of circulating biomarkers representing inflammation (C-reactive protein, interleukin-6, monocyte chemoattractant protein-1, tumor necrosis factor receptor 2, osteoprotegerin, fibrinogen), endothelial dysfunction (intercellular adhesion molecule), vascular damage (CD40-ligand, P-selectin, lipoprotein-associated phospholipase A2) and oxidative stress (urinary isoprostanes) in participants free of diabetes who attended the Offspring 7th (n=2499) or multi-ethnic Omni 2nd (n=189) examination of the Framingham Heart Study (19982001). Biomarker concentrations were log-transformed and standardized (mean= 0, standard deviation=1); multivariable logistic regression was used to test each biomarker in association with incident diabetes (defined as: 1) fasting glucose level of 126 mg/dL and over or 2) use of insulin or oral hypoglycemic medications) at 6.6 years mean follow-up (20052008). We adjusted for age, sex, cohort, and additionally for established clinical covariates related to diabetes (body mass index, fasting glucose, systolic blood pressure, HDL cholesterol, triglycerides and smoking).

RESULTS: In a total of 2638 participants (56% women, mean age 59 years), at follow-up, 162 participants (6.1%) developed diabetes. C-reactive protein, fibrinogen, intercellular adhesion molecule, interleukin-6, urinary isoprostanes, monocyte-chemoattractantprotein-1 and tumor necrosis receptor factor 2 were associated with incident diabetes after adjusting for age, sex and cohort (all p-values <0.02). However, none of the inflammatory biomarkers remained significant after multivariable adjustment (all p>0.05). The c-statistic for prediction of diabetes was 0.89 in the multivariable model including only clinical covariates.
CONCLUSION: We demonstrated associations between biomarkers from multiple different pathways in association with incident diabetes, which were absent after additional adjustment of established clinical covariates. Inflammatory biomarker panels may not be an effective resource to adequately predict diabetes onset in community-based samples.
RACIAL AND ETHNIC DISPARITIES IN RECEIPT OF THE HERPES ZOSTER VACCINE: RESULTS OF A NATIONAL POPULATION-BASED SURVEY Deirdre Mooney 1; Janice Weinberg 2; Christine Lloyd-Travaglini 2; Karen Lasser1. 1Boston University School of Medicine, Boston, Massachusetts ; 2Boston University School of Public Health, Boston, Massachusetts . (Tracking ID # 10660)
BACKGROUND: Herpes Zoster (HZ) vaccination decreases illness due to shingles, yet despite national guidelines, the vaccine is underutilized. Racial and ethnic disparities in receipt of other vaccines such as influenza and pneumococcal are well documented, yet few data are available regarding HZ vaccine receipt.
METHODS: We analyzed population-based data on 13,086 adults age 60 and older from the 2008 and 2009 National Health Interview Survey (NHIS), a nationally representative sample of the civilian non-institutionalized population. We used Chi square tests to compare receipt of HZ vaccine according to respondents demographic characteristics, access to care, and receipt of influenza and pneumococcal vaccine. To analyze race as a predictor of HZ vaccine receipt, we used multiple logistic regression controlling for sex, age, immigrant status, education, marital status, insurance type, income, region of the country, and having a usual site of care or care provider (all significant bivariable predictors of HZ vaccine receipt). We accounted for NHIS stratification, clustering and sampling in the multivariable analysis.
RESULTS: Only 8.1% of eligible adults reported receiving the HZ vaccine. There were racial differences in receipt, with blacks (3.7%) and Hispanics(3.5%) receiving the vaccine less often than whites (9.8%; p Whites were2.2 times more likely to receive the HZ vaccine than were blacks and Hispanics, while they were 1.2 times more likely to receive the influenza vaccine and 1.5 times more likely to receive the pneumovax. HZ vaccination was more common among those who received the influenza or pneumococcal vaccine (10.7% and 12.8%) relative to those who had not received these vaccines (4.3% and 3.9 %, respectively; p Foreign-born individuals were also less likely to receive the vaccine (OR 0.62; 95% CI0.43-0.88; p=0.008) as were those without a usual source of care (OR0.53; 95% CI 0.29-0.96; p=0.04). Persons with Medicaid or no insurance were less likely to report vaccination than those with other insurance including Medicare and private insurance (OR 0.37; 95% CI 0.25-0.57; pMidwest versus the West (OR 0.68; 95 CI 0.52-0.90; p=0.008 and OR0.70; 95% CI 0.57-0.88; p=0.002, respectively).
CONCLUSION: Racial and ethnic disparities exist in HZ vaccine receipt, with minorities having lower vaccination rates regardless of income, insurance type or having a usual source of care. Logistical barriers unique to the HZ vaccine (high cost, Medicare part D reimbursement, and need for freezer storage) may pose particular challenges to minority patients and the institutions that serve them. Multilevel interventions that increase patient and provider awareness of the vaccine and develop systems to promote vaccine uptake are needed to eliminate racial and ethnic disparities.

KNOWLEDGE, ATTITUDES AND PRACTICES REGARDING SMOKING AND CESSATION ADVICE: A SURVEY OF PHYSICIANS IN BUENOS AIRES Jonatan Konfino 1; Raul Mejia 1; Adriana Basombrio2. 1Hospital de Clinicas, University of Buenos Aires, Buenos Aires, N/A ; 2Direccion de SIDA, Gobierno de la

Ciudad de Buenos Aires, Buenos Aires, N/A . (Tracking ID # 10661)
BACKGROUND: The efficacy of the Highly Active Antiretroviral Therapy (HAART) has transformed HIV/AIDS into a chronic disease. In Argentina, the infectologist assumes the role of being the patients primary care physician, which might result in scarce use of preventive measures and provision of tobacco cessation assistance.
METHODS: A cross sectional study was conducted in Buenos Aires, Argentina in 2010 to assess physicians knowledge, attitudes and current practices with regard to providing smoking cessation advice to their HIV-positive patients.
RESULTS: 169 infectologists were invited to participate and 128 completed the survey (75%), 61% were women and 66% worked at public hospitals. The median age was 39 years and 19% smoked. 90% indicated that they advise their patients to quit smoking, 17% that they set a quit date with the patient, 23% provide brief advice on tobacco cessation, 35% prescribe any pharmaceutical aid, 8% recommend the use of web sites for quitting, 5% suggest the use of phone quit lines and 17% use behavioral-cognitive treatment. 40% of participants considered that treating tobacco addiction was their responsibility but 92% considered that these patients should be referred to a specialist on cessation. The main barriers they reported to deliver tobacco cessation assistance were not having enough time (84%) and being trained inadequately on tobacco cessation (73%). CONCLUSION: Most of infectologists reported treating tobacco addiction but they do not use evidence based strategies for cessation. Not having enough time and being inadequately trained were the main barriers they found for providing assistance forquitting. The provisionof training in tobacco cessation to the infectologists might reduce tobacco consumption among people living with HIVand would have a significant positive effect on their health.
EVALUATION OF RILONACEPT FOR PREVENTION OF GOUT FLARES DURING INITIATION OF URATE-LOWERING THERAPY: RESULTS OF A PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL Robert R Evans 1; Robert Terkeltaub 2; H Ralph Schumacher 3; Kenneth G Saag 4; James Clower 5; William Jennings 6; Jian Wang 1; Shirletta King-Davis 1; Steven P Weinstsin1. 1Regeneron Pharmaceuticals, Inc., Tarrytown, New York ; 2VA Medical Center, San Diego, California ; 3VA Medical Center and University of Pennsylvania, Philadelphia, Pennsylvania ; 4University of Alabama at Birmingham, Birmingham, Alabama ; 5Westside Center for Clinical Research, Jacksonville, Florida ;
6Radiant Research, San Antonio, Texas . (Tracking ID # 10664)
BACKGROUND: While attaining serum uric acid levels <6.0 mg/dl is critical to the long-term management of gout, gout flares (GFs) are often precipitated as serum uric acid levels fall during the initial months of urate-lowering therapy (ULT). This phase 3 study evaluated the efficacy and safety of rilonacept, an interleukin-1 (IL-1) blocker, for the prevention of GFs during initiation of ULT with allopurinol. METHODS: This multicenter trial included adults with gout (1977 ARA preliminary criteria), uric acid levels >7.5 mg/dL, and self-reported history of 2 or more GFs in the previous year. Eligible patients were initiated on allopurinol 300 mg daily (or lower dose in those with renal dysfunction) with subsequent titration to achieve uric acid <6 mg/dL and randomized to receive treatment (Tx) with weekly subcutaneous (SC) injections of placebo (Pbo; n=80), rilonacept 80 mg (R80; n=80), or rilonacept 160 mg (R160; n=81) (loading dose on Day 1). GFs were reported by the patient via interactive voice response diary; GFs were treated, as appropriate, with NSAIDs or oral glucocorticoids while continuing weekly SC injections and allopurinol Txs. The primary endpoint was the mean number of GFs over the 16 week Tx period. Other endpoints included the percent of patients with 1 or more GFs, and the number of GFs during each 4 week Tx period through week 16. Safety and tolerability were also assessed.
RESULTS: Baseline characteristics were similar among treatment groups;92.9% were male, the mean (SD) age was 52.3 (12.6) years, and the number of flares reported in the prior year was 4.6 (3.3). By week 2 median serum uric acid levels decreased to 6.0 mg/dL in the R groups and 6.2 mg/dL in the Pbo group. Through week 16, the mean number of GFs per patient (primary endpoint) was significantly lower in both R groups relative to

Pbo:1.06 for Pbo; 0.29 for R80 (95% CI, 0.20 to 0.60; p=0.0003 vs Pbo), and 0.21 for R160 (95% CI, 0.14 to 0.41; p<0.0001 vs Pbo). From day 1 to week 16, the proportion of patients who experienced one or more GFs was 46.8% Pbo (95% CI, 35.5 to 58.4) vs 18.8% R80 (95% CI, 10.9 to 29.0) vs 16.3% R160 (95% CI, 8.9 to 26.2; p<0.0001 for both comparisons), resulting in an 60% and 65% reduction in the respective R groups. The number of GFs per Tx period is shown in Table 1.
The overall incidence of adverse events (AE) was similar between Pbo(60.8%) and rilonacept (63.4%). Injection site reactions (generally mild) were the most frequent AE with rilonacept compared with placebo (1.3% Pbo, 8.8% R80, 19.8% R160). Other common AEs included respiratory infections, musculoskeletal system disorders, and headache, and rates were similar among the treatment groups. Three patients in each group experienced serious AEs; no rilonacept-related SAEs, deaths, or serious infectious AEs were reported.
CONCLUSION: This phase 3 trial confirmed that IL-1 blockade with rilonacept markedly reduced the occurrence of gout flares during initiation of urate-lowering therapy. Rilonacept demonstrated an acceptable safety and tolerability profile.

SOCIOECONOMICAL FACTORS, TOBACCO CONSUMPTION AND RELATED ATTITUDES IN YOUTH IN ARGENTINA. A MULTILEVEL ANALYSIS Raul Mejia 1; Bruno Linetzky 2; Daniel Ferrante2. 1Hospital de Clinicas, University of Buenos Aires, Buenos Aires, Argentina ;
2Ministry of Health, Buenos Aires, Argentina . (Tracking ID # 10665)
BACKGROUND: Adolescence is the time in life when tobacco consumption begins. There is no evidence about the relation between socioeconomic factors and tobacco prevalence in youth in Latin America. The objective of this study is to investigate associations of socioeconomic status (SES) with tobacco consumption and related attitudes in adolescents from Argentina.

METHODS: We used the 2007 Global Youth Tobacco Survey (GYTS) which asses tobacco use among 13 to 15 years old youths who go to school. The GYTSs variables used were: current smokers, smokers who want to quit now, never smokers susceptible to start smoking within the next 5 years, second hand smoke exposure outside home, adolescents who by single cigarettes, agreement with prohibition of smoking in public places. Information about the SES of the neighborhood of the school was obtained from national statistics. We used three variables: neighborhood with Convergent Poverty (households with insufficient economic capacity to purchase basic goods and services for subsistence); school public or private and; schools with social assistance (provision of free breakfast and lunch for students).The statistical analysis includes the description of the weighted prevalence of each individual variable for each socioeconomic level and school characteristic. A multilevel analysis was done using random intercept logistic regression model.
RESULTS: We used the 2007 Global Youth Tobacco Survey (GYTS) which asses tobacco use among 13 to 15 years old youths who go to school. The GYTSs variables used were: current smokers, smokers who want to quit now, never smokers susceptible to start smoking within the next 5 years, second hand smoke exposure outside home, adolescents who by single cigarettes, agreement with prohibition of smoking in public places. Information about the SES of the neighborhood of the school was obtained from national statistics. We used three variables: neighborhood with Convergent Poverty (households with insufficient economic capacity to

purchase basic goods and services for subsistence); school public or private and; schools with social assistance (provision of free breakfast and lunch for students).The statistical analysis includes the description of the weighted prevalence of each individual variable for each socioeconomic level and school characteristic. A multilevel analysis was done using random intercept logistic regression model. CONCLUSION: Students from schools located at poor neighborhoods are more susceptible to start smoking, have a higher prevalence of smoking, are exposed more frequently to second hand smoking than those who attend schools from wealthier neighborhoods. These results provide evidence to the implementation of tobacco control policies in schools from low SES neighborhoods.

THE TIMING OF ANTIBIOTIC FILLS RELATIVE TO AMBULATORY VISITS Jeffrey A. Linder 1; Mark W. Friedberg 2; Dana P. Goldman 3; Daniella Meeker4. 1Brigham and Womens Hospital/Harvard Medical School, Boston, Massachusetts ; 2Brigham and Womens Hospital/Harvard Medical School/RAND Corporation, Boston, Massachusetts ; 3RAND Corporation/University of Southern California, Los Angeles, California ; 4RAND Corporation, Santa Monica, California . (Tracking ID # 10666)

BACKGROUND: Most analyses of antibiotic use in the United States have focused on visit-based antibiotic prescribing, with the assumption that antibiotics prescribed for acute infections will be used promptly. However, patients may delay their use of antibiotics longer than clinicians intend and clinicians may prescribe antibiotics without seeing patients face-to-face. We sought to describe the relationship between the timing of antibiotic prescriptions filled by patients and their most recent ambulatory visit.

METHODS: We performed a retrospective analysis of medical and prescription drug insurance claims of employees from a large multinational corporation for patients aged 18 to 64 years old from January 2001 to December 2007. We identified claims for patients filling antibiotic prescriptions plausibly intended to treat acute infections (i.e., antibiotic durations between 4 and 21 days and short-duration azithromycin). We then identified the most recent ambulatory visit preceding each antibiotic claim, identified the visit diagnosis, and calculated the time interval between the visit and the antibiotic claim. In order to isolate single episodes of care, we considered only the first of multiple fills when less than a month elapsed between sequential fills.

RESULTS: During the study period, 125,132 patients (mean age 44 years old [standard deviation, 13 years], 48% male) filled 324,987 antibiotic prescriptions that were plausibly intended to treat acute infections. The most commonly prescribed antibiotic classes were penicillins (36% [standard error for all percentages, <1%]), macrolides (29%), cephalosporins (15%), and tetracyclines (5%). Eight percent of antibiotic prescription fills occurred within 1 day of the preceding ambulatory visit, 14% within 4 days, 48% within 30 days, and 71% within 60 days. The median length of time between patients filling an antibiotic prescription and the most recent visit was 33 days. There was no outpatient visit within the preceding 90 days for 28% of antibiotic prescription fills. The most common diagnoses for the visits immediately prior to antibiotic prescription fills were acute respiratory infections (ARIs; 60%; median days to fill, 28), urinary tract infections (UTIs; 8%; median days to fill, 20), acne (7%;

median days to fill, 28), and cancer screening (5%, median days to fill, 44). Overall, 25% of the most recent ambulatory visits had diagnoses that did not include ARIs, UTIs, acne, or other infections (median days to fill, 51).
CONCLUSION: The majority of antibiotic prescription fills occur more than a month after patients most recent ambulatory visit, indicating a large proportion of antibiotics are either not filled promptly or are prescribed by clinicians in the absence of closely antecedent ambulatory visits.
RANDOMIZED CONTROLLED TRIAL OF MEDICAL HOME FEATURES TO REDUCE CARDIOVASCULAR RISK Barbara J Turner 1;
Christopher Hollenbeak 2; Pandit Kavita 3; Shelly Joseph 3; Mark Weiner4. 1University of Texas Health Science Center San Antonio, San Antonio, Texas ; 2Penn State College of Medicine, Hershey, Pennsylvania ; 3University of Pennsylvania, Philadelphia, Pennsylvania ; 4University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania . (Tracking ID # 10673)
BACKGROUND: The patient-centered medical home offers services and tools that may reduce coronary heart disease (CHD) risk and blood pressure in vulnerable populations. We conducted a randomized, controlled trial in African-American primary care patients with uncontrolled hypertension to evaluate the impact of an intervention using practice-based registry, staff support and community-based peer coaches on predicted CHD risk and systolic blood pressure after 6 months.

METHODS: A single-blind, randomized, controlled trial of behavioral support to reduce CHD risk was conducted in two level 3 NCQA certified, academic general medicine practices in the University of Pennsylvania Health System. A practice-based electronic medical record (EMR) registry was used to identify African-American patients aged 4075 with uncontrolled hypertension, defined as a mean blood pressure above goal over a two-year period with at least one reading >10 mmHg above goal. Peer coaches were recruited and trained from among African-American patients with well controlled hypertension according to the same practicesEMR registry or from local community volunteers. Eligible subjects were recruited from July 2007 to November 2009. The intervention group received telephone-based lifestyle counseling by peer coaches to reduce CHD risk every other month for six months and educational visits to primary care staff on alternate months (two visits). All subjects received brochures about healthy foods and lifestyle. The primary outcome was 6 month change in predicted 4-year risk of a CHD event, based on a model developed by DAgostino, for intervention versus control groups, and the secondary outcome was change in systolic blood pressure. Multiple imputation was used to estimate missing values for intent-to-treat analysis. Sensitivity analyses were conducted to evaluate comparability of completers versus non-completers.
RESULTS: Of 566 eligible patients, the 280 (49%) randomized subjects were characterized by: mean age 62 (SD 8.8); 65% women, 53% diabetes mellitus, and 18% had prior CHD or equivalent. Baseline 4-yr CHD risk did not differ significantly for the 136 intervention and 144 control subjects (5.8% and 6.4%, respectively). In both groups, mean baseline systolic blood pressure was 140.5 mmHg. Follow-up for 4-year CHD risk was competed in 76% of subjects and for systolic blood pressure in 88% of subjects. In an intent-to-treat analyses, the intervention group had greater reductions in both CHD risk (difference 0.8%, P=0.023) and systolic blood pressure (difference 7.1 mmHg, P=0.001). After adjustment, these significant differences persisted as well as for a reduction in diastolic blood pressure (P=0.023). Reduction in systolic blood pressure was similar for completers versus non-completers for the CHD risk analysis. One patient died in each study arm.
CONCLUSION: In this randomized, controlled trial, components of the medical home that included using a registry to identify at-risk hypertensive African-American patients and an intervention combining community- and office-based behavioral support produced clinically significant reductions in predicted 4-yr CHD risk and blood pressure. This trial supports the potential for the medical home to produce improved clinical outcomes in vulnerable populations.

MAMMOGRAPHY KNOWLEDGE, ATTITUDES, AND PHYSICIAN RECOMMENDATION AND EDUCATION: DOES PRIOR SCREENING MATTER? Edson Carias 1; Alfred Rademaker 1; Dachao Liu 1; Connie Lea Arnold 2; Terry Davis4. 1Northwestern University, Chicago, Illinois;
2LSU Health Sciences Center, Shreveport, Louisiana. (Tracking ID # 10676)

BACKGROUND: Although many interventions have successfully increased the rate of initial mammography use, the factors that prevent the consistent use of repeat screenings remain a growing focus in health-services research. Probable barriers to repeat screening may be worse in disadvantaged populations. The purpose of this study is to evaluate potential differences in breast cancer screening knowledge, attitudes, and physician recommendation and education between women who have had prior mammograms but are not up-to-date and those who have never been screened.

METHODS: Eligible participants (females, age 40 years and over) who had never had a mammogram or were not up to date on their mammogram screening (defined as not having had a mammogram for more than two years) were enrolled in six Federally Qualified Health Centers (FQHCs) in Louisiana. Structured surveys with questions about mammogram screening knowledge, attitudes, self-efficacy, and physician recommendation and education were administered to each participant. Literacy was assessed with the Rapid Estimate of Adult Literacy in Medicine (REALM). Chi-square tests were conducted for data analysis. Multivariate logistic regressions adjusted for age, literacy, and race.

RESULTS: Among the 937 female participants enrolled in our study, 65% were African-American, 35% were white, 30% had less than a high school diploma, and 44% read on less than a 9th grade level. Participants ranged in age from 40 to 89, with a median age of 52. Approximately 24% of participants had never received a mammogram (N=227). Participants who never had a mammogram were less likely than previously-screened participants to have heard of any tests that find breast cancer (71% vs. 89%, $p<0.0001$). Similarly, when compared to those who have had a mammogram, women who have never had a mammogram were less likely to know someone with breast cancer (64% vs. 78%, $p=0.0001$). Participants who have never had a mammogram were less likely to report knowing what it was (75% vs. 99%, $p<0.0001$), having had a physician recommendation for a mammogram (66% vs. 87%, $p<0.0001$), or having been given information or education on mammograms (28% vs. 68%, $p<0.0001$). Interestingly, approximately one in three FQHC participants who had previously been screened reported having never been given information or education on mammograms. Both groups reported having seen or heard an advertisement about breast cancer screening (85% vs. 80%, $p=0.13$). Although both groups had positive attitudes towards screening benefits, those who have never had a mammogram were more likely to agree that they were afraid of getting one because they might find out that something is wrong (26% vs. 13%, $p<0.0001$). Women who never had a mammogram were less likely to know where to get a mammogram (77% vs. 83%, $p<0.0001$) or less likely to know how to get a mammogram (69% vs. 85%, $p<0.0001$). The two groups showed no difference in literacy levels ($p=0.76$). Results remained significant after adjusting for age, race, and literacy. CONCLUSION: Participants who had not previously been screened had less knowledge about mammography and were less likely to have received a physician recommendation or education for a mammogram. Women who did not previously have a mammogram were less confident with the logistics of getting a mammogram, as well as dealing with the results of a mammogram. It is important for clinicians to provide counseling about the benefits of regular screening and explicit information about obtaining a mammogram.

PHYSICIANS DIALOGUES WITH TERMINAL LUNG CANCER PATIENTS: TRENDS WITH SHARED DECISION MAKING AND PATIENT FRIENDLY EDUCATION Elizabeth Edwardsen 1; Sally Rousseau 2; Diane Morse 3; Shmuel Reis 4; Mary Gale Gurnsey 2; Adam Taupin 2; Cleveland Shields 5; Jennifer Griggs 6; Susan McDaniel2. 1University of Rochester, Rochester, New York ; 2University of Rochester, Rochester, New York ; 3University of Rochester School of Medicine, Rochester, New York ; 4Rappaport Institute, Haifa, N/A ; 5Purdue University, West Lafayette, Indiana ; 6University or Michigan, Ann Arbor, Michigan . (Tracking ID # 10682)

BACKGROUND: Patient-centered care is respectful of and responsive to individual patient values, preferences and needs. This approach is a foundation of high-quality health care outcomes including safety, effectiveness, efficiency, and equity. Patient-centered care promotes patient autonomy. Shared decision making considers the patients perspective and involves defining problems, providing information and presenting options so patients can participate in care decisions. Patients

with terminal cancer speak with their physicians about treatment options, symptom management, and morbidity and mortality concerns. These health issues can lead to complex dialogues, allowing potential opportunities for insights into the study of patient-physician communication. The objective of this study is to examine physician communication with respect to shared decision making and patient friendly education with terminal cancer patients.
METHODS: Design: Consenting physicians had covert audio recordings of office visits with Sps (standardized patients). Population: Practicing physicians: 23 community oncologists and 23 community family physicians of which SPs successfully audio-recorded 19 oncologists and 20 family physicians. Physicians averaged 48.1 (SD=9.2) years old. Seventy-one percent were male and 29% were female. SPs were all male. Prompted physicians were able to identify the SP correctly in 15% (n=5) of visits which were subsequently removed from the data set, leaving 34 undetected visits for this study. Analysis and text management: We conducted a thematic analysis of the transcripts, using an iterative process to create a coding system, with key words and phrases in areas of interest. Two team researchers, randomly paired, coded each transcript. Coding development continued until saturation; with each revision all previously coded interviews were recoded by a minimum of 2 researchers. We resolved differences in coding in the larger research group by consensus. Team members then reviewed all coded elements in context, using sequence analysis to understand shared decision-making, patient-friendly education and patient-centered approaches to medical care. Dialogue categories included: 1) decision-making, shared or not shared, 2) patient education, patient-friendly or medical jargon and 3) approach to medicine, patient-centered or physician-centered. RESULTS: Thirty-two of 34 (94%) encounters contained dialogue with decision making. Of these utterances, 48 % (n=104) were coded as shared decision-making and 52 % (n=114) were not shared. Word counts for patient encounters were comparable for family physicians and oncologists. Percent word counts for the family physicians ranged from 24-78%, average 56% and median 58%. Respective counts for the oncologists were 31-83%, average 62% and median 66%. The absolute word counts were on average 10% higher for the family physicians. Despite this difference, shared decision making utterances were more prevalent (4:1) for the oncologist group compared with the family physicians. Family physicians, as a subgroup, were coded for non-shared decision making 2:1 to shared decision-making. Both physician groups utilized patient friendly education more commonly than medical jargon (6:1 for family physicians and 4:1 for oncologists). Both physician groups used similar approaches to medicine with patient-centered and physician-centered utterances. However, the oncologists leaned slightly more towards patient-centered encounters. Shared decision-making dialogues included: I think you need to understand your standing and your options, You can even decide now what you want to do, and I will respect your decision. Unshared dialogues included: well I want to check some blood work today we probably need to do a couple of scans too and see how thats done, and We need to get you in to see an oncology doctor. Patent-centered approaches included: Now in terms of symptoms in the lungs and pain what symptoms are you having right now? Patient-friendly education included: Well Ill tell you what, lets look at it and well get youand if nothing looks really serious here today, I mean lets hope nothing acutethen well get you an appointment with the oncologist. CONCLUSION: Elements of shared decision-making and patient-friendly education were identified in the vast majority of patient-physician encounters. In this set of encounters the oncologists exhibited more shared

decision-making (possibly due to greater comfort and exposure to terminal cancer patients). Patient-friendly education abounded in most encounters. Continued medical education and research are indicated to expand and explore this trend toward
patient-centered care and shared decision-making with all patient populations. ACKNOWLEDGEMENT OF FUNDING: This project was supported by NCI grant R21CA124913 for Dr. Shields and NIMH T32 MH18911 PI Eric Caine for Dr. Morse.
DUTY HOURS Kevin Volpp 1; Judy Shea 2; Dylan Small 2; Mathias Basner 2; Jingsan Zhu 2; Laurie Norton 2; Adrian Ecker 2; Cristina Novak 2; Lisa Bellini 2; David Dinges2. 1Philadelphia VA; University of Pennsylvania School of Medicine and Wharton, Philadelphia, Pennsylvania ;
2University of Pennsylvania, Philadelphia, Pennsylvania . (Tracking ID # 10686)
BACKGROUND: The Accreditation Council for Graduate Medical Education (ACGME) recently released new duty hour standards that will restrict interns to working 16-hour shifts. This is a controversial set of new regulations that stemmed from a recent Institute of Medicine Report that suggested curtailing the duration of shifts for interns either by shortening them or through widescale use of mandatory naps for extended duty overnight shifts. Previous research has indicated that naps on extended duty shifts for interns have low adherence rates and do not succeed in significantly increasing amount slept while on call, suggesting this is not a viable policy solution. We undertook this study to determine whether a system of mandatory naps for interns was feasible and could result in significant increases in the amount slept while on extended duty overnight shifts.
METHODS: 98 intern months at the Philadelphia VA Medical Center (PVAMC) and 75 intern months on the oncology unit of the Hospital of the University of Pennsylvania (HUP) were randomly assigned to either receive a standard intern schedule, which involved extended duty overnight shifts of up to 30 hours, or a mandatory nap month, in which interns were given protected time from 1230530 am in which they were expected to sign out their cell phones to a covering resident. The schedule was a residency programmatic initiative; study participants were asked to wear wrist watch actiwatches and complete sleep diaries. The primary outcome was mean hours slept during extended duty overnight shifts as measured by Actiwatch Spectrum wrist activity monitors. Secondary outcomes included percentage of call nights with no sleep and mean hours slept during other nights of the call cycle. The analyses were done using an unadjusted intent-to-treat analyses testing for differences between the intervention and control groups at each of the two sites, analyzing each site as a separate trial. To account for the correlation among a participants multiple observations, all of the analyses used Huber-White robust standard errors with individual participants as the clusters.
RESULTS: Interns on mandatory nap rotations at both PVAMC and HUP had significantly higher amounts of mean sleep during the protected periods (PVAMC: 2.6 vs. 1.6 hours, p-value<0.0001; HUP: 2.8 vs. 1.9 hours, p-value<0.0001). Nap month participants were also significantly less likely to have call nights with no sleep (PVAMC: 12.5% vs. 26.9%, p-value<0.0001; HUP: 11.1% vs. 17.1%, p-value 0.04). However, mean amount slept over the full call cycle was no different in the control and intervention groups (PVAMC 6.7 vs. 6.8 hours, p-value 0.50; HUP: 6.7 vs. 6.5 hours, p-value 0.19).
CONCLUSION: A mandatory nap intervention significantly increased mean amount slept during overnight call nights, which in the context of new ACGME regulations restricting duty hours could provide a useful alternative for programs seeking to comply with ACGME guidance on fatigue management for residents. However, overall mean sleep within each call cycle was unchanged, suggesting that while this approach could help with acute sleep deprivation, it would be unlikely to address problems with chronic sleep deprivation among residents.

EFFECTS OFA PATIENTACTIVATION INTERVENTION TO OVERCOME CLINICAL INERTIA TO CONTROL BLOOD PRESSURE Christopher N Sciamanna 1; Jeffrey Thiboutot1. 1Penn State Milton S. Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 10687)

BACKGROUND: Hypertension is a common chronic disease known to have many adverse health effects. Unfortunately, physicians have a tendency not to intensify their treatment of hypertension in response to uncontrolled blood pressure values; this tendency has been labeled clinical inertia. This trial was aimed at determining the impact of providing patients with tailored, web-based feedback to help them know when to ask questions aimed at intensifying their hypertension care. METHODS: Diagnosed hypertensive patients (n=500) were enrolled in this RCTand randomized to one of two study groups: (1) Intervention condition Web-based hypertension feedback, based on the individual patients self-report of health variables and previous BP measurements, to prompt them to ask questions during their next physicians visit about hypertension care (e.g., What can you do help me lower my blood pressure); (2) Control conditionWeb-based preventive health feedback, based on the individuals self-report of receiving preventive care (e.g., pap testing). The feedback gave participants questions to ask which they could discuss with their primary care provider (PCP) at their next visit. The primary outcome of the study is change in blood pressure and change in the percentage of patients in each group with controlled blood pressure (RESULTS: Of 500 patients enrolled at baseline, 418 (83.6%) completed the 1-year follow up visit. Most (82.2%) participants utilized the intervention during at least 6 of 12 months, though this did not differ between groups. In addition, most (61.2%) participants reported asking questions directly from the web-site with no difference between study groups. As an example of the control condition (preventative maintenance), if participants had not received a recent tetanus shot they were prompted to ask their PCP if they might benefit from receiving one. Significantly more patients in the control group reported discussing this with their PCP (30.9% control, 13.9% intervention; p<0.001). This led to significantly more subjects in the control group (20.7% control, 8.7% intervention, p=0.005) reporting receiving a tetanus shot in the past year at follow-up. As a similar example of the intervention condition (hypertension care), if participants had not received a creatinine test or urine protein in the past year, they were prompted to ask their PCP if they might benefit from such tests. Significantly more participants from the intervention condition reported discussing creatinine testing (45.8% intervention, 30.2% control; p=0.009) and urine protein testing (40.3% intervention, 30.2% control; pCONCLUSION: The use of a patient activation intervention designed to overcome clinical inertia for hypertension care did not lead to more changes in hypertension medication use or blood pressure control. This was despite high levels of adherence, which led to positive changes in the use of preventive care services (e.g., tetanus immunization) as well as hypertension care services (e.g. creatinine testing, urine protein testing). By providing patients with individually tailored questions to ask during their PCP visits, this study demonstrated that participants were likely to discuss the questions with their PCP. These discussions led to changes in care, demonstrating that the feedback led to a positive change in the health management process.

THE RELATIONSHIP BETWEEN PREGNANCY INTENTION AND PRECONCEPTION HEALTH BEHAVIORS IN A NATIONAL SAMPLE OF REPRODUCTIVE-AGE WOMEN Cynthia H. Chuang 1; Marianne M. Hillemeier 2; Anne-Marie Dyer 1; Carol S. Weisman1. 1Penn State College of Medicine, Hershey, Pennsylvania ; 2Penn State University, State College, Pennsylvania . (Tracking ID # 10695)

BACKGROUND: While the causes of adverse pregnancy outcomes are only partially understood, it is known that predictors include unintended pregnancy and suboptimal preconception health behaviors. Moreover, the nonpregnant phases of a womans reproductive life have important implications for her own health as well as for future pregnancy outcomes. However, it is not well understood whether women recognize these risks, and how intention for future pregnancy impacts health behaviors. The objective of this study was to describe smoking, alcohol use, and folic acid supplementation in preconception women and determine if the likelihood of healthy preconception behaviors differs by whether and when women intend future pregnancy. METHODS: Analysis was based on 36,949 nonpregnant women in the 2004 Behavioral Risk Factor Surveillance System (BRFSS) who were of reproductive age (1844 years), sexually active, and capable of future pregnancy. The association between future pregnancy intention (intending pregnancy in less than 12 months from now, between 12 months

to less than 2 years from now, in 2 or more years from now, not wanting to have a child in the future, or not sure/ambivalent) and preconception behaviors (any smoking, more than 7 alcohol drinks/week, and daily folic acid supplementation) was determined. Multivariable logistic regression models adjusted for diabetes, weight category, race/ethnicity, marital status, education, income, and any children under 18 living in the household (a proxy for prior pregnancy). RESULTS: Women intending pregnancy in less than 12 months had lower rates of smoking (18.5%), lower rates of at-risk alcohol use (4.4%), and higher rates of folic acid supplementation (54.3%) than other women. However, in adjusted analysis, only the odds of folic acid supplementation remained higher in women intending pregnancy in the next 12 months (adjusted OR 1.49, 95% CI 1.15-1.92) compared with women not intending future pregnancy. Women intending pregnancy later or ambivalent about future pregnancy were no more likely to be engaging in healthy preconception behaviors than women not intending future pregnancy. CONCLUSION: In this large, nationally representative population-based study, women intending pregnancy within 12 months were more likely to use folic acid, but pregnancy intention was not associated with preconception smoking or at-risk alcohol use in adjusted analysis. These findings support growing evidence that other than folic acid supplementation, women do little to change their health behaviors before pregnancy. Future research to understand determinants of preconception health behaviors is needed to inform future interventions aimed at reducing preventable adverse pregnancy outcomes.

EMERGENCY DEPARTMENT UTILIZATION BY PRIMARY CARE PATIENTS ATAN URBAN SAFETY-NET HOSPITAL Karen Lasser 1; Jeffrey Samet 1; Howard Cabral 2; Andrea Kronman1. 1Boston University School of Medicine, Boston, Massachusetts; 2Boston University School of Public Health, Boston, Massachusetts. (Tracking ID # 10696)

BACKGROUND: Patient Centered Medical Homes seek to reduce emergency department (ED) utilization by primary care patients. Few data are available on such utilization at safety-net hospitals. METHODS: We analyzed data on patients who had 1 primary care visit in the past year (July 1, 2009-July 1, 2010) to Boston Medical Center. Using ICD-9 codes for the principal ED visit diagnosis, we defined ED utilization according to a modified version of the NYU ED algorithm, categorizing ED visits as high, intermediate, and low severity. Such classification has a strong association with future hospitalization or death. We defined a frequent ED utilization group with 4 ED visits in the past year, and an occasional ED utilization group with 13 ED visits in the past year. Medical and psychiatric diagnoses were obtained from the EMR problem list and billing data. We used t-tests and chi-square tests to compare demographic characteristics of patients with and without any ED use. Controlling for age, gender, language, insurance, and the presence of medical and

psychiatric diagnoses, we used multiple logistic regression to analyze predictors of frequent vs. occasional ED utilization.

RESULTS: Among 39,593 patients who had seen their primary care provider in the past year, 65.4% had no ED visits over that period. The 34.6% (13,710/39,593) with 1 ED visit made 30,048 ED visits, with a mean of 2.2 visits (IQR 12). Frequent utilizers, accounting for 14.1% of all primary care patients with any ED use, made 41% of all ED visits by primary care patients. Most ED visits made by high utilizers were categorized as low severity (72.2%); 8.8% were high severity, and the remaining 19% were indeterminate severity. Patients with and without any ED use did not differ by language (79% spoke English) or gender (57% female). Patients with ED use were older (mean age 46.9) than persons without ED use (mean age45.8; t <0.0001). A higher proportion of blacks (43.2%) and Hispanics(42.9%) used the ED, relative to Asians (17.7%) and whites (20.1%; p<0.0001). ED utilization by privately insured patients (21.3%) was less than that by patients with Medicaid and Free Care (44.9% and 46.0%, respectively; p<0.0001). Among patients with any ED use, frequent ED utilizers were of similar age (mean 47) yet had a higher burden of medical and psychiatric comorbidity compared to occasional

utilizers. In multivariable analyses, frequent (vs. occasional) ED utilizers were more likely to be under age 50 (odds ratio [OR] 1.2; 95% confidence interval [CI], 1.1-1.3), to have COPD (OR 1.8; 95% CI, 1.6-2.0), diabetes (OR 1.3; 95% CI, 1.1-1.4), CHF (OR 2.1; 95% CI, 1.8-2.5), bipolar disorder (OR 1.6; 95% CI, 1.3-2.0), anxiety (OR 1.3; 95% CI, 1.1-1.5), schizophrenia (OR 1.6; 95% CI, 1.2-2.1), depression (OR 1.7; 95% CI, 1.5-1.8) and PTSD (OR 1.6; 95% CI, 1.3-1.8). CONCLUSION: ED utilization by primary care patients at an urban safety-net hospital was high, though most visits were low-severity. A medical home model which provides adequate access to psychiatric as well as primary care, and chronic disease management, has the potential to decrease non-emergent ED utilization.

BLOOD PRESSURE MEASUREMENT BIASES IN CLINICAL SETTINGS Jewell Halanych 1; Susan Andreae 1; Andrea Cherrington 1; Michelle Martin 1; Maria Pisu 1; Louise Russell 2; Monika Safford1. 1University of Alabama at Birmingham, Birmingham, Alabama; 2Rutgers, New Brunswick, New Jersey. (Tracking ID # 10698)

BACKGROUND: An article in JAMA(2008;299:28422844) reported that blood pressure (BP) measurement in clinical care settings seldom follows the protocol recommended by the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC). This may lead to over- or underestimates of the number of patients with controlled BP. We evaluated BP measurement modality as a source of bias in determining BP control.

METHODS: We evaluated BP measurement biases in the context of a community-based randomized trial in underserved, rural diabetic patients. Clinical BP was measured by community clinical staff instructed to take the participants BP like you do in your own clinic. Research BP was measured by personnel trained and certified according to an established research protocol in compliance with JNC recommendations. Each participant had both types of BP assessment during study enrollment on the same day over the course of 2 hours, with the clinical BP assessed first, most closely simulating clinical settings. Both BP assessments were conducted using an automated LifeSource Blood Pressure Monitor (Model UA 789). RESULTS: The study sample included 227 diabetic participants (mean age 59 years, 86% African-American, and 75% female). As shown in the Table, mean clinical BP was higher than mean research BP by 5 mmHg for systolic BP (SBP, $p<0.001$) and 2 mmHg for diastolic BP (DBP, $p<0.001$), with greater differences for participants >65 years old. As shown in the Figure, using SBP >130 or DBP >80, the proportion of participants who were uncontrolled was 8% higher when using clinical versus research BP measurement ($p<0.001$). Using higher cut-offs

TABLE. Mean BP for 227 diabetic patients measured using a typical
clinical protocol and research protocol.

(SBP >140 or DBP >90), the proportion of participants uncontrolled was 10% higher when using clinical versus research BP measurement ($p<0.001$). The difference was 14% in participants >65 years old. CONCLUSION: Measurement biases in clinical settings may be an important component of observed low BP control rates in real-world settings. Per a 2002 NIH report, measuring blood pressure 5 mmHg too high would falsely classify 27 million persons as having HTN. At the cost of $1,000 per year to treat a patient, thiswould add $27 billionto the Nations healthcare billto treat a nondisease. Efforts to reduce this measurement bias may have a beneficial impact on treatment burden, medication costs, and quality of care measures.

CONTRACEPTIVE CARE IN THE VA HEALTHCARE SYSTEM Sonya Borrero 1; Maria Mor 2; Xinhua Zhao 2; Melissa McNeil 1; Said Ibrahim 3; Patricia hayes4. 1University of Pittsburgh, Pittsburgh, Pennsylvania ; 2VA PittsburghHealthcare System, Pittsburgh, Pennsylvania ; 3VA Medical Center, Philadelphia, Pennsylvania ; 4Women Veterans Health Strategic Health Care Group, Washington D.C., District of Columbia . (Tracking ID # 10702)

BACKGROUND: High quality, equitable contraceptive care is a growing priority in the Department of Veterans Affairs (VA) as the number of women veterans using the VA health care system continues to rise. The objective of this study was to examine contraceptive use within the VA by race/ethnicity and to determine whether

receiving primary care in a VA womens health clinic enhances contraceptive provision.
METHODS: We used national VA administrative databases to describe use of contraceptive methods among female veterans aged 1845 who made at least 1 visit to either a VA womens health clinic (WHC) or a traditional VA primary care clinic (PCC) in fiscal year (FY) 2008. The outcome variable for this study was a prescription or procedure indicating contraceptive use during FY 2008. The primary predictor variables of interest were patient race/ethnicity (Hispanic, non-Hispanic black, and non-Hispanic white) and receipt of care in a WHC. Covariates included socio-demographic information, medical diagnoses that may impact choice of contraceptive method, number of visits, whether the subject had a VA gynecology visit, geographic location, and whether the site was a hospital- or community-based clinic. Chi-square tests were used to compare variables by race/ethnicity. We examined the bivariate relationships between each covariate and contraceptive use and computed the unadjusted odds ratios for each pair. We then used multivariable regression models to examine the associations between race/ethnicity and receipt of care in a WHC with contraceptive use while controlling for potential patient-level and facility-level confounders. RESULTS: A total of 103,950 women veterans were included in the study cohort: 6% were Hispanic, 39% white, and 24% black. Approximately 45% of women had been seen in a WHC. Nearly 70% of women did not have any other insurance. Only 22% of women had documented use of any contraception. After adjusting for potential confounders, Hispanic and black women had significantly lower contraceptive use compared to white women (OR: 0.82; 95% CI: 0.76-0.88 and OR: 0.85; 95% CI: 0.82-0.89, respectively). Women who had received care in a WHC were significantly more likely to have contraception compared to those who received care in a PCC (OR: 2.05; 95% CI: 1.97-2.14), and this trend was seen across all race/ethnicity categories. Other factors significantly associated with higher rates of contraception in the adjusted analysis included younger age, not being married, increasing frequency of clinic visits, having seen gynecology, presence of non-VA insurance, being seen in a hospital-based clinic, and a diagnosis of migraines with aura. A diagnosis of breast cancer, tobacco use and age >35, stroke, coronary artery disease, and diabetes were all associated with a significantly less likelihood of having any contraceptive method.
CONCLUSION: We found that overall contraceptive use in the VA is low, especially among minority women. We also found that receipt of primary
care in a VA womens health clinic is associated with significantly higher rates of documented contraception.
HIGH CONCORDANCE BETWEEN DERMATOLOGISTS AND GENERAL INTERNISTS IN IDENTIFYING DERMATOLOGIC CONDITIONS INTERNISTS SHOULD BE ABLE TO MANAGE Oluwatumininu Johnson 1; Carrie Mahowald 2; Miguel Sanchez2. 1NYU School of Medicine, Brooklyn, New York; 2New York University School of Medicine, New York, New York. (Tracking ID # 10705)
BACKGROUND: Studies reveal that a low percentage of Generalists accurately diagnose dermatologic cases, and that a significant amount of referrals from Generalists are ultimately deemed unnecessary. In our setting, a large urban ambulatory care center and Primary Care Internal Medicine Residency training site serving a medically indigent, racially, ethnically and linguistically diverse community, dermatologic conditions are common, and specialty services are limited. We therefore set out to identify dermatologic conditions that both Dermatologists and General Internists believe Internists should be able to diagnose and manage, with the overall goal of building a targeted teaching tool for Internists, to aid in improved patient care and prevention of unnecessary referrals.
METHODS: After a thorough review of the relevant literature and records of referrals at our practice site, we conducted five facilitated focus groups using a purposive sampling method to assess the self perceived needs of generalists and the perspective of dermatological consultants on that need: 3 groups of General Internists (n of 15, 2, 10) and 1group of Dermatology Residents (10) and 1 group of Attendings (2). Near identical questions were posed and each group was asked to generate a list of dermatologic conditions that Internists should be able to diagnose and treat. The Dermatologists focus groups also had to generate conditions that were often

misdiagnosed or unnecessarily referred from the Internist to the Specialist. All focus groups were audio recorded, transcribed and analyzed independently by each investigator using the Atlas TI software and then themes identified were compared, discussed and a consensus on findings was reached. This project was approved by our institutional IRB.
RESULTS: There was a high level of agreement on both dermatologic conditions General Internists should feel comfortable diagnosing and treating, and on the perceived weaknesses of the Generalist in diagnosis and treatment. The top ten most common and/or pertinent of these areas were then selected as the focus for our curriculum. These areas are: general skin care, the skin exam and common dermatologic nomenclature, drug eruptions, suspicious moles, dermatitis, alopecia, acne, lower extremity lesions (stasis dermatitis, cellulitis and vasculitis), common dermatologic outpatient procedures, and fungal infections. In addition, we have collected a rich data set on barriers to and preferences for learning this material which informed the development of a multi-component curriculum that includes on-line multi-media (text, pictures, algorithms and animations), and expert precepted live patient practice components.
CONCLUSION: By improving the acumen and confidence of General Internists in these needs-based areas of Dermatology, it would in turn enhance quality and efficiency of patient care in our under-served, urban community.
INTERNET BASED DEPRESSION PREVENTION FOR ADOLESCENTS: 2.5 YEAR FOLLOW-UP Benjamin N/A Van Voorhees 1; Monika Marko-Holguin1. 1The University of Chicago, Chicago, Illinois. (Tracking ID # 10711)
JGIM
ABSTRACTS
S115
BACKGROUND: We conducted a long-term follow-up study of a primary care/Internet-based depression prevention intervention for adolescents (CATCH-IT), Competent Adulthood Transition with Cognitive-Behavioral Humanistic and Interpersonal Training).
METHODS: We elected to examine Internet site related outcomes for the entire cohort: 1) the number of times and the types of coping strategies used in the previous two weeks; 2) depressed mood, automatic negative thoughts, perceived social support and perceived school impairment at2.5 year follow-up compared to baseline.
RESULTS: N=44, 53% of available sample, N=83 consented to participate. A majority of participants in follow-up study (54%, N=20) reported using 1 to 2 coping strategies favoring behavioral activation approaches in the last 2 weeks (M=1.8, SD=1.9). The most commonly used coping strategies were Changing negative thoughts (CBT, 29.7%, N=11) and Changing my activities to be more active with people or fun things (BA, 16.2%, N=6). Less utilized strategies included avoiding procrastination (2.7%, N=1) and relationship problem solving (5.4%, N=2). Significant declines at 2.5 years were found for Center for Epidemiologic Studies Depression (CES-D, M=22.2 versus M=13.5, p-value=0.001) scores, automatic negative thoughts (M=36.09 versus M=16.98, p-value=0.001) and educational impairment (M=9.00 versus M=5.31, p-value=0.03) when compared to the scores at baseline and 68 weeks (active period of intervention) post intervention. Scores of perceived social support from friends or family were stable and/or improved from baseline to 2.5-year follow-up. CONCLUSION: Half of those who participated in the long-term outcome study reported ongoing and recent use of CATCH-IT coping strategies. Moreover, their depressed mood, automatic negative thoughts and educational impairment levels remained significantly below those measured at enrollment.
GAPS IN MEDICAL STUDENTS KNOWLEDGE OF THE LINK BETWEEN OBESITY, LIFESTYLE, AND CANCER David P. Miller 1;
Mara Z. Vitolins 1; Stephen W. Davis 1; Sonia J. Crandall 1; Edward H. Ip 1; Karen S. Vaden 1; John G. Spangler1. 1Wake Forest University School of Medicine, Winston-Salem, North Carolina. (Tracking ID # 10714)

BACKGROUND: Over two-thirds of Americans are overweight or obese. This obesity epidemic has generated much attention in mainstream media, including concern over obesitys link with heart disease and diabetes mellitus. However, entering medical students may be less aware of the increased risk of cancer associated with excessive weight, poor diet, and lack of exercise. To help guide the development of medical school obesity curricula, we conducted a needs assessment to determine first year medical students baseline knowledge of the link between cancer risk, obesity, and lifestyle factors.
METHODS: The study was conducted at a single medical school in the southeast. For two consecutive years, first year students participated in a new obesity curriculum developed by members of the research team and delivered via web-based modules. Each module began with a 5 item multiple choice pretest to prime the learner. Pretest questions were randomly drawn from a pool of 10 questions for each module. We examined the pretest results to determine specific gaps in students baseline knowledge of the link between cancer with obesity, diet, and exercise. Prior to analysis, a group of 3 multidisciplinary team members coded each pretest item as cancer related or non-cancer related. Coding discrepancies were resolved by group consensus.
RESULTS: Of 242 students, 175 (72.3%) completed two of the modules and were included in the analysis. Ten pretest questions were cancer related (4 obesity items, 4 dietary items, and 2 physical activity items). The remaining 10 pretest items were non-cancer related. Overall, students scored worse on the cancer-related items than the non-cancer related items
(mean correct score 47% vs. 55%, $p<0.001$). A minority of students knew that obesity caused the greatest increased risk for uterine cancer (6%), properly identified foods associated with increased cancer risk (27%), or understood the relationship between exercise and cancer risk (31%). Similarly, a minority of students knew that 1020% of cancer deaths worldwide can be attributed to obesity, but approximately two-thirds (62%) overestimated the magnitude of risk. Only 2 items were answered correctly by at least two-thirds of students: knowing that obesity is associated with gastrointestinal cancers and knowing that whole grains and fiber can lower colorectal cancer risk. CONCLUSION: Students enter medical school with significant gaps in their awareness of how cancer risk is affected by obesity, diet, and exercise. Given that weight and lifestyle are modifiable risk factors, medical school obesity curricula should include information on cancer risk.
ETHICS EDUCATION ACROSS THE CURRICULUM: HOW DO MEDICAL STUDENTS RELATE PRE-CLINICAL LEARNING TO CLINICAL EXPERIENCE? Lauris C. Kaldjian 1; Laura Shinkunas 1; Valerie Forman-Hoffman 1; Marcy Rosenbaum 1; Jerold Woodhead 1; Lisa Antes 1; Jane Rowat1. 1University of Iowa Carver College of Medicine, Iowa City, Iowa. (Tracking ID # 10715)
BACKGROUND: Ethics education in medical school occurs predominantly during the pre-clinical years. Little is known about how the cognitive content of this education is remembered, perceived, and applied after students enter the clinical environment.
METHODS: We gathered data from third-year medical students during Internal Medicine and Pediatrics clerkships at the University of Iowa in 200708 through (1) a voluntary written survey and (2) content analysis of required written reflections about ethical and professional issues encountered during these clerkships. The survey queried: attitudes toward the clinical relevance of their second-year ethics course; knowledge about four ethical principles, other sources of ethical value, and a systematic approach to ethical reasoning taught and practiced in their second-year ethics course (using: A Clinicians Approach to Clinical Ethical Reasoning. JGIM 2005;20:306311); and perceptions about ethics in the clinical environment. Three investigators used content analysis to identify ethical principles, other sources of ethical value, and goals of care in students written reflections. NVivo qualitative software and SAS were employed to calculate frequency and chi-square statistics. Students prior performance data from the second year (from a paper and a multiple choice exam during the ethics course) were also examined.
RESULTS: From a class of 141 third-year students, 109 (77.3%) were included for analysis based on completion of study components. The four ethical principles were recalled by most students (beneficence95.4%,

nonmaleficence 95.4%, autonomy 71.6%, justice 82.6%), but other sources of ethical value were recalled less frequently (rights11.9%, consequences 10.1%, comparative cases 16.5%, professional guidelines 18.4%, conscientious practice 21.1%). Out of 15 possible items within the systematic approach to clinical ethical reasoning taught in the second year, 34.9% of students cited 03 items, 50.5% cited 46, and 14.7% cited 79. Content analysis of reflections showed that no one of the four ethical principles was mentioned in more than 16% of reflections, and goals of care were mentioned in only 14.7%; by contrast, consequences were mentioned in 51.4%. Students who scored 90-100% on the multiple choice exam in the second-year ethics course were able to recall more sources of ethical value (P=0.02) and were more likely to refer to goals of care in their reflections (P=0.02). Most students believed the content of the second-year ethics course was relevant to medical practice (71.6%) and helped prepare them for the challenges they faced in the clinical environment (58.7%), that ethics and medicine are inseparable (93.6%), that they are able to recognize key ethical

obligations and challenges (96.3%), and apply a systematic approach to clinical ethical reasoning (65.1%). Students were more likely to believe that ethical and professional values in the clinical environment are practiced (71.6%) than discussed (44.0%).
CONCLUSION: Most third-year medical students in this study appear to recognize the clinical relevance of ethics and be satisfied with their pre-clinical ethics education. Though most can recall the names of four ethical principles, few are able to recall the names of other sources of ethical value or describe most of the components of a systematic approach to clinical ethical reasoning.

HOUSING INSTABILITY AND INCIDENT HYPERTENSION IN THE CARDIA COHORT Maya Vijayaraghavan 1; Margot Kushel 1; Eric Vittinghoff 2; Stephan Kertesz 3; David Jacobs 4; Cora Lewis 4; Steve Sidney 5; Kirsten Bibbins-Domingo1. 1Division of General Internal Medicine/SFGH, University of California, San Francisco, San Francisco, California ; 2Department of Epidemiology/Biostatistics, University of California, San Francisco, San Francisco, California ; 3Division of Preventative Medicine, University of Alabama at Birmingham, Birmingham, Alabama ; 4Division of Epidemiology, University of Minnesota, School of Public Health, Minneapolis, Minnesota ; 5Kaiser Permanente, Northern California Division of Research, Oakland, California . (Tracking ID # 10716)
BACKGROUND: Housing instability, a precursor to homelessness, may be an independent social and environmental risk factor for hypertension, but limited prospective data exist. We sought to determine if housing instability in early adulthood was associated with incident hypertension over 15 years of follow-up in the Coronary Artery Risk Development in Young Adults (CARDIA) study. Because causes of housing instability vary by race and sex, we hypothesized that housing instability would exert a differential effect on incident hypertension by race and sex.
METHODS: CARDIA is a study of 5,115 young adults, recruited from four sites in 19856 when they were 1830 years of age. The cohort is balanced by race (black/white), sex, age and education, and has been followed with periodic exams over 20 years. At Year 5, when participants were 2335 years of age, all available CARDIA participants were asked about housing; of these, 4342 did not have hypertension and were analyzed. We defined housing instability as living in overcrowded conditions (> 2 people per bedroom), moving 8 or more times in 2 years, or occupying a place without paying rent or money. We defined incident hypertension as systolic blood pressure >140 or diastolic blood pressure >90 or being on anti-hypertensive medications. We used pooled logistic regression to estimate the independent association between housing instability and incident hypertension at years 7, 10, 15 and 20 adjusting for age, sex, race, income, education, smoking, alcohol, cocaine, amphetamine use, marital or relationship status, marital or relationship problems, children, and body mass index (BMI). Because the effect of housing instability varied by race and sex, we report stratified results.
RESULTS: Of the 4342 participants without hypertension at Year 5, 370(8.5%) were living in unstable housing

with prevalence 5.0% (59/1179) among white women, 6.6% (69/1052) among white men, 11.7% (142/ 1212) among black women and 11.1% (100/899) among black men. Within the entire cohort housing instability was not associated with incident hypertension after adjusting for demographics, socioeconomic status, behavioral risk factors, social factors, and BMI (Adjusted Odds Ratio (AOR) 1.2, 95% CI 0.9-1.7). However, this association varied by race and sex (p-value for interaction <0.001). Incident hypertension between years 5 and 20 occurred in 10.8% (121/1120) of stably housed white women vs. 28.8% (17/59) of unstably housed white women. Unstably housed white women had greater odds of incident hypertension (AOR 6.7, 95% CI 3.2-13.7) compared to stably-housed white women. There was no association with incident hypertension for unstably housed white men (AOR 0.8, 95% CI 0.4-1.8), black women (AOR 0.9, 95% CI 0.6-1.6), or black men (AOR 1.0, 95% CI 0.6-1.8) compared to stably housed adults in each race-sex subgroup. CONCLUSION: In a biracial cohort of young adults, housing instability was associated with incident hypertension in white women, but not in white men, black women, or black men. Given the discordance in our findings by race and sex, housing instability may represent different phenomenon for black and white men and women. Some literature suggests that early-life psychosocial risk factors known to be associated with homelessness may be different for women and whites, compared to men and blacks. On this basis, we speculate that psychosocial stressors associated with housing instability may contribute to the development of incident hypertension in unstably housed white women.

IMPACT OF PRICE DISCOUNTS WITH AND WITHOUT MESSAGING ON SUGARY BEVERAGE CONSUMPTION: RESULTS FROM A MULTI-SITE INTERVENTION Matthew Press 1; Jane Jue 2; Daniel McDonald 3; Kevin Volpp 2; Jingsan Zhu 2; Nandita Mitra 2; David Asch 2; George Loewenstein3. 1Weill Cornell Medical College, New York, New York;
2University of Pennsylvania, Philadelphia, Pennsylvania; 3Carnegie Mellon University, Pittsburgh, Pennsylvania. (Tracking ID # 10722)

BACKGROUND: Some policymakers interested in curbing increases in obesity and diabetes have advocated taxing the purchase of sugary beverages. The objective of our study was to determine if an alternative financial incentivea price discount for zero calorie beverageswould affect consumers beverage choice. In addition, we sought to assess whether messaging about the discount would augment its effectiveness. METHODS: This was a nonrandomized, prospective trial of two interventions carried out at the cafeterias and stores of three different hospitals. The first intervention was a 10% discount on all zero calorie bottled beverages, including water, diet soda, and diet iced tea. The second intervention was a 10% discount on all zero calorie bottled beverages plus messaging to consumers about the discount. Messaging was in the form of marketing posters, which were displayed prominently and conveyed a connection between the discount and a healthier beverage choice. Each intervention lasted three weeks, and prices reverted to baseline between the interventions. Sales of sugary beverages and zero calorie beverages during the interventions were compared to pre- and post-intervention periods using overdispersed Poisson regression. Covariates in the regression model included day of the week and total number of transactions (to adjust for customer volume), and the regression coefficients were converted to percent change in sales. RESULTS: During the discount intervention, sales of sugary beverages at the three sites increased 6.5% (p=.276), decreased 10.8% (p=.004), and increased 5.6% (p=.000); sales of zero calorie beverages increased 4.7% (p =.383), increased 15.2% (p=.001), and increased 3.0% (p=.098), respectively, relative to baseline. During the discount plus messaging intervention, sales of sugary beverages increased 5.0% (p=.277), decreased 10.3% (p=.008), and increased 1.4% (p=.313); sales of zero calorie beverages increased 11.7% (p=.007), increased 23.9% (p=.000), and increased 1.0% (p=.577), respectively, relative to baseline.

CONCLUSION: In response to the price discount intervention, sugary beverage purchases decreased, and zero calorie beverage purchases increased, at one of the three sites. At that site, messaging appeared to augment the effect of the discount. However, at the other sites, the interventions had no or modest effects at increasing

zero calorie beverage purchases, and, in these cases, the effects were at least partially offset by increases in purchases of sugary beverages. The impact of financial incentives, such as price discounts, on consumer consumption of sugary beverages may vary in different settings. Policies based on these interventions require further evaluation before widespread implementation.

FACTORS ASSOCIATED WITH ADDRESSING BARRIERS TO ACCESSING CANCER CARE IN A PATIENT NAVIGATION PROGRAM

Azadeh Nasseh 1; Karen M Freund 1; Sharon Bak 1; Kristine Beaver 1; Timothy Heeren 2; Tracy A Battaglia1. 1Womens Health Unit, Section of General Internal Medicine, Evans Department of Medicine, Boston Medical Center and Boston University School of Medicine, Boston, Massachusetts ; 2Boston University School of Public Health, Boston, Massachusetts. (Tracking ID # 10729)

BACKGROUND: Patient navigation, which aims to reduce barriers to care, is increasingly being adopted as a model to reduce cancer health disparities in underserved communities across the country. Although studies are ongoing to assess the full benefit of this model on cancer care outcomes, there is little understanding of the process of navigation to achieve these outcomes. In this study, we examine documented barriers to care and corresponding navigation activities to address them.

METHODS: Data from the intervention arm of a multi-site quasi-experimental patient navigation study included eligible women with abnormal Mammogram or Pap tests from 5 urban community health centers, during January 2007 to December 2008. Navigators were trained to identify, document and address 20 pre-defined barriers to care at each patient encounter. The goal of navigation was to engage in activities to ameliorate these barriers in order to facilitate timely diagnostic resolution of the abnormality. In each patient encounter, navigators documented unique barriers and corresponding actions taken to address that barrier. Based on literature review and consensus of the research committee, access barriers were grouped into 3 types: Logistic (e.g. Transportation), Cultural (e.g. Fear) and Financial (e.g. Employment). A barrier is considered addressed when there is a corresponding documented action (e.g. Arrangement for Transportation). Our analyses used the barrier as the unit of analysis and examined associations between patient characteristics and types of barrier with whether or not a barrier was addressed. Patients can contribute multiple barriers from multiple visits, and we used Generalized Estimation Equation (GEE) multiple logistic regression to examine these associations, accounting for correlation between multiple observations per subject.

RESULTS: Among 1118 female intervention subjects, mean age was 42 years; 67% were non white; 71% had either public or no insurance. Overall, 602 (54%) subjects had 1 or more unique barriers identified across all encounters. This resulted in 1691 unique barriers to care of which 620 (37%) were Logistic, 167 (10%) were Cultural and 71 (4%) were Financial; almost half 833 (49%) of documented barriers did not fit into one of the predefined categories and were documented as Other. Overall 72% of the identified barriers were addressed. The Other barrier category had the lowest percentage of addressed barriers (59%), followed by Financial (79%), Logistic (84%) and Cultural barriers (92%). In bivariate analysis, using GEE model, Other barriers were less likely (OR:0.29, CI: 0.21, 0.4) and Cultural barriers were more likely (OR: 2.4, CI:1.2, 4.6) to be addressed compared to Logistic barriers. In bivariate analyses, African American women compared to White women had a lower odds of having an addressed barrier (OR: 0.64, CI: 0.42, 0.97) as did those from two community health centers (OR: 0.2, CI: 0.1, 0.4 and OR: 0.25, CI: 0.13, 0.48). In Multivariate GEE model, using type of barriers and adjusting for race, age, marital status, language, type of insurance and site of care to assess whether or not a barrier was addressed; type of barrier (Other barriers vs. Logistic barriers, OR: 0.32, CI: 0.23, 0.46, and Cultural barriers vs. Logistic barriers, OR: 2.67, CI:1.34, 5.35) and belonging to one of the community health centers (OR:0.33, CI: 0.15, 0.77) were the only significant predictors of the outcome. CONCLUSION: In this community health center-based navigation program, navigators addressed most identified barriers when they

were able to clearly categorize the barrier. After adjusting for site of care and barrier type, no individual patient characteristic was found to be associated with the ability of a navigator to address an identified barrier. This suggests that navigator training, which targeted 20 known barriers to care, provided navigators with the skills necessary to address those known barriers yet highlights unmet navigator training needs that are specific to the population served across each site of care.

PHARMACISTS PERSPECTIVES ON A PHARMACIST-LED CARE TRANSITIONS INTERVENTION: WHAT CAN WE LEARN FROM PILL-CVD? Sunil Kripalani 1; Katherine Taylor-Haynes 1; Alison Oberne 2; Courtney Cawthon 1; Jeffrey L Schnipper3. 1Vanderbilt University, Nashville, Tennessee ; 2University of South Florida, Tampa, Florida ; 3Brigham and Womens Hospital, Boston, Massachusetts. (Tracking ID # 10735)

BACKGROUND: Increasingly, institutions are implementing multi-faceted programs which seek to improve hospital discharge transitions. However, little is known about which aspects of these complex interventions are most beneficial. The Pharmacist Intervention for Low Literacy in Cardiovascular Disease (PILL-CVD) study was a two-site randomized trial designed to reduce serious medication errors after hospitalization through a tailored educational intervention and telephone follow-up. The current qualitative study sought to determine the most important aspects of the intervention from the perspectives of the pharmacists who delivered it.

METHODS: Semi-structured interviews were conducted with the 11 study pharmacists to examine their perspectives on pharmacist involvement in the different aspects of the PILL-CVD intervention, including medication reconciliation, two in-hospital patient counseling sessions, and provision of simple medication adherence aids. Also, while telephone follow-up was conducted initially by non-clinical personnel, pharmacists followed up when problems were identified. Interview data were coded systematically using an a priori analytic framework, RE-AIM+, that expands upon Glasgows (1999) evaluation framework of Reach, Efficacy, Adoption, Implementation, and Maintenance.

RESULTS: Pharmacists considered medication reconciliation the most important facet of the intervention. They frequently identified errors in

the Pre-Admission Medication List (PAML) as documented by treating physicians. A careful medication review by the pharmacist identified patients with poor understanding of their pre-admission medication regimens, pinpointed errors in patients medical records, and enabled creation of a complete, accurate medication list, but this process was considered time-consuming and likely imperfect. Adherence aids (e.g., pill box, illustrated daily medication schedule) were felt to be highly valuable for patients with low health literacy, though pharmacists found them less useful for higher health literacy patients. Having non-clinical staff conduct the initial post-discharge follow-up calls effectively leveraged pharmacists time and hospital resources.

CONCLUSION: Medication reconciliation and use of simple adherence aids were felt to be the most beneficial aspects of this multi-faceted care transition intervention. This experience supports greater pharmacist involvement in medication reconciliation, either to verify the work of other health care providers or to construct the PAML from the outset. Additional refinements to the patient education tools may be needed to increase their utility for patients with adequate health literacy, though another solution would be to provide such tools only to patients with low health literacy. A protocol for post-discharge telephone follow-up by non-clinical personnel leveraged pharmacists time and could reduce the cost of similar interventions.

PATIENT AND PHYSICIAN DISCUSSIONS AFTER DECISION SUPPORT FOR COLORECTAL CANCER SCREENING IN THE ELDERLY Carmen Lewis 1; Christopher P DeLeon 1; Michael P Pignone 1; Carol Golin1. 1University of North Carolina - Chapel Hill, Chapel Hill, North Carolina. (Tracking ID # 10736)

BACKGROUND: The potential benefit of colorectal cancer screening decreases with increasing age and co-morbidity. Individualized decision making between elderly patients and their providers has been recommended to encourage screening in those most likely to benefit from screening and to avoid harm in those most likely to experience net harm. This study has 2 purposes: 1) To assess the feasibility of providing targeted decision

support intervention for both physicians and elderly patients prior to an office visit and audio-taping visits and 2) to examine individualized decision making during the visit through an analysis audiotapes of the visits.
METHODS: We recruited a convenience sample of 6 physicians and their patients who were age 70 and older, not up to date with CRC screening, and were scheduled for an upcoming appointment Prior to the visit we provided patients with a decision support booklet targeted to elderly patients. Physicians were given a bar graph showing life expectancy estimates divided by quartiles of health state and targeted to the patients age and gender. Visits were audio-taped, transcribed and coded for elements of individualized decision making.
RESULTS: Among 71 eligible patients, 20 (28%) agreed to participate with the majority declining because of the audiotaping. Twelve of the 20 encounters (60%) had discussions of CRC screening, defined as 3 verbal exchanges between physician and patient. The average discussion time was 6 minutes (range 1 to 22). Two of the 12 discussions were initiated by the patient. The patients health status was discussed in 7 encounters and in 3 of these encounters screening was discussed in the context of the patients other health issues. In 4 encounters, the USPSTF recommendations that screening is not routinely recommended for older adults were discussed. Decisions in favor of screening were made in 7 encounters (6 for FOBT; 1 colonoscopy); no decisions were made explicitly to discontinue screening permanently, but 3 patients preferred not to get screening at the current visit and for 2 the decision about screening was deferred. In 6 encounters, the physicians assessed patient understanding, 2 physicians discussed the potential benefits of screening, 2 physicians discussed the potential harms, and 2 physicians discussed uncertainty in the decision.
CONCLUSION: Our decision support tool triggered discussions in over half of participants who agreed to be audiotaped. Discussion was initiated primarily by physicians. Most discussions included considerations of limited life expectancy and an assessment of patient understanding, but fewer discussed benefits, harms, and uncertainty in the decision.
IMPLICATIONS OF DECLINING CABG RATES ON RACIAL DIFFERENCES IN CABG HOSPITALVOLUME
Peter W Groeneveld 1; Feifei Yang 1; Gina Pugliano 1; Lin Yang1. 1University of Pennsylvania, Philadelphia, Pennsylvania. (Tracking ID # 10737)
BACKGROUND: Coronary artery bypass grafting (CABG) has declined in frequency in the United States during the past decade. It is uncertain if this decline has been similar among white and black patients. Because hospitals may be unlikely to abandon their cardiac surgery programs despite declining surgical volumes, it is also unclear if declining CABG volumes have increased the proportion of whites and blacks receiving CABG at low-volume hospitals. Prior research indicates patients at hospitals with low CABG volumes (i.e., less than 150 cases/ year) have worse surgical outcomes than patients at high-volume centers.
METHODS: Medicare claims from 2001 to 2008 for patients age 65 and older were analyzed to determine the number of white and black patients undergoing CABG in each year. Hospital identifiers on these claims were used to determine the annual number of U.S. hospitals providing CABG services. The total Medicare CABG volume at each hospital was calculated for both 2001 and 2008, and hospitals with fewer than 75 Medicare-reimbursed CABGs were designated as low-volume centers (Medicare CABGs constitute approximately 50% of all CABGs, thus hospitals with fewer than 75 Medicare CABGs were likely to be low-volume centers). The percentages of black and white patients undergoing CABG in low-volume hospitals in 2001 were compared to the corresponding percentages of black and white patients undergoing CABG at low-volume hospitals in 2008.
RESULTS: There was a 27% decrease in the annual volume of CABGs among white Medicare patients from 2001 (152,000 cases/year) to 2008 (111,400 cases/year), but the decline among black Medicare patients was only 14% between 2001 (7,242 cases/year) and 2008 (6,248 cases/ year) ($p<0.001$ for the difference in slopes). The number of U.S. hospitals offering CABG increased by 11% from n=1,039 in 2001 to n=1,154 in 2008 ($p<0.001$). The percentage of white CABG patients undergoing surgery at hospitals with low CABG volumes increased from 8% in 2001 to 16% in 2008 ($p<0.001$). The percentage of black CABG patients undergoing surgery at low-CABG-volume hospitals increased from 13% in 2001 to 21% in 2008 ($p<0.001$).

CONCLUSION: The decline in CABG volume during 20012008 was more pronounced among white patients than among black patients, suggesting that over time, whites were more likely than blacks to receive alternative treatment for severe coronary artery disease. Despite the national decline in CABG volume, we observed a paradoxical increase in the number of U.S. hospitals performing CABG surgery. Hence, there was a substantial increase in the fraction of all CABGs performed at low-volume centers, but the proportion of black CABG patients at low-volume centers was substantially greater than the proportion of white CABG patients at low-volume centers. If low-volume hospitals persistently have worse CABG

outcomes than high-volume centers, these findings portend increasing racial disparity in CABG outcomes over time.

NEIGHBORHOOD CHARACTERISTICS ASSOCIATED WITH ACCESS TO PATIENT-CENTERED MEDICAL HOMES Jaya Aysola 1; John Z. Ayanian2. 1Harvard Medical School, Boston, Massachusetts ; 2Dept. of Health Care Policy, Harvard Medical School, Boston, Massachusetts. (Tracking ID # 10738)

BACKGROUND: Patient-centered medical homes have gained prominence as models to promote high quality, cost-effective primary care. Evidence for significant racial/ethnic and geographic disparities in access to medical homes exist, however, the factors contributing to these disparities are not well established. Our study examined whether community characteristics, such as social cohesion, built environment, and perceived neighborhood safety are associated with access to patient-centered medical homes and are potential contributors to this disparity in access for children.

METHODS: We analyzed the 2007/2008 National Survey of Childrens Health (NSCH), a nationally representative cross-sectional survey of parents/guardians of children, ages 017, that assessed neighborhood characteristics and access to a medical home (n=84,474). Our main outcome was access to a patient-centered medical home, measured by a composite score constructed from a total of 19 NSCH survey questions based upon the American Academy of Pediatrics medical home definition. Our primary predictors were neighborhood cohesion, perceived community safety, the built environment measured by the number of neighborhood amenities (e.g. parks, sidewalks), and the number of neighborhood detractors (e.g. vandalism). For the predictors determined to be significantly associated with medical home access in unadjusted analyses, a multivariable logistic regression model including all predictors assessed access to a medical home, adjusting for age, gender, race, insurance type and status, poverty level, parental education level, primary language, family structure, household employment status, geographic region, and children with special health care needs. Analyses were conducted with SUDAAN software to account for the complex survey design.

RESULTS: Over 93% of all children had access to a personal provider and usual source of care. Access to medical homes was reported for 62% of all children and was more common among children who were Non-Hispanic white, privately insured, in higher income households, and without special health care needs. Adjusted analysis revealed three of our four predictors were independently associated with access to a medical home. Children living in communities perceived as unsafe were less likely to have access to a medical home as compared to children living in communities perceived as safe (adjusted OR 0.70; 95% CI: 0.69,0.79). Children living in neighborhoods with one amenity as compared to those with four amenities, were also less likely to have access to a medical home (OR 0.72; 95% CI: 0.62, 0.84). Similarly, children living in less cohesive neighborhoods were less likely to have access to a medical home than those living in very cohesive neighborhoods (not cohesive: OR 0.54; 95% CI 0.48, 0.61; somewhat cohesive: OR 0.72; 95% CI 0.65,0.80; cohesive: OR 0.81; 95% CI 0.74, 0.89).

CONCLUSION: Our study suggests that several neighborhood characteristics are independently associated with access to a patient-centered medical home. Understanding the social and environmental factors that

impede access to new models of health care delivery is essential to informing policies that reduce disparities in access to such models. Efforts to increase patient-centered medical homes in such at risk, disadvantaged communities should be a priority to improve primary care for children.

ASSOCIATION OF PRE-TREATMENT NUTRITIONAL STATUS WITH CHANGE IN CD4 COUNT AFTER INITIATION OF ANTIRETROVIRAL THERAPY AT 6, 12, AND 24 MONTHS IN RWANDAN WOMEN

Elizabeth Kiefer 1; Donald Hoover 2; Qiuhu Shi 3; Jean-Claude Dusingize 1; Mardge Cohen 4; Eugene Mutimura 5; Kathryn Anastos1.

1Montefiore Medical Center, Bronx, New York ; 2Rutgers University, Piscataway, New York ; 3New York Medical College, Valhalla, New York ;

4Rush University, Chicago, New York ; 5Kigali Health Institute, Kigali, New York. (Tracking ID # 10739)

BACKGROUND: HIV infection and malnutrition are prevalent in Africa. Rwandan women share a greater burden of HIV than men, and malnutrition (using World Health Organization definition of body mass index (BMI) <18.5 kg/m2) is common (approximately 19%) in our preliminary studies of HIV-positive Rwandan women. Low serum albumin and BMI have been shown to independently predict increased mortality in several African studies. However, macro-and micro-nutrient supplementation have failed to consistently show reductions in HIV mortality. It is thus unclear whether these malnutrition measures simply mark more advanced HIV disease, and there are scant data on the effect of nutritional status on response to antiretroviral therapy (ART). As ART becomes more available in the low income countries, it is crucial to understand the association between poor nutrition and response to ART. We hypothesized that poorer nutritional status would be associated with poorer gains in CD4 count after ART initiation. METHODS: This analysis was done on 537 Rwandan Womens Interassociation Study and Assessment (RWISA) participants who initiated ART after study entry and had at least six subsequent months of follow up. RWISA is a population-based observational cohort study of 710 ART-naive HIV + and 226 HIV-negative women who enrolled in 2005 and seen at six-month visits. At these visits, health and health behavior data were collected, including whether women initiated ART (exact dates of ART initiation and medication regimen were determined), physical exams performed, and biologic specimens collected and stored. Medical care was provided by non-governmental and national health organizations, separately from the RWISA study. Following World Health Organization (WHO) and Rwandan guidelines, women were eligible for ART if they had; WHO Stage IV disease, irrespective of the CD4 cell count; WHO Stage III disease with CD4 cell counts <350 cells/L, or CD4 <200/L regardless of clinical stage. The study outcomes were changes in CD4 count at follow up visits 63, 123, and 243 months after ART initiation. Indicators of nutritional status collected from the study visit prior to ART initiation that were used in these analyses included BMI, albumin, fat adjusted for (height)2, fat free mass (FFM) adjusted for (height)2, and sum of skinfold measurements at the thigh, triceps and subscapular muscles. Resistance and reactance obtained from bioelectric impedance measurements were used in standard formulae to calculate FFM and fat. Other covariates used included age, income in Rwandan Francs (FRW), education, pre-ART CD4 count (per 100 cells/ L) and history of AIDS defining illness (ADI) prior to ART initiation. Nutritional variables were examined in univariate linear regression models of CD4 change. Multivariate linear regression models of change for each nutritional variable were fit using backwards selection.

RESULTS: 537 women initiated ART at a mean age of 35 years. Mean (within 6 months) preART CD4 count was 216 cells/ L. Prior to ART, the mean BMI was 21.6 kg/m2 (18.3% of the women classified as malnourished), mean albumin 3.4 g/dL; mean adjusted fat 4.70 kg/m2,
mean adjusted FFM 17.1 kg/m2; and mean sum of skinfold measurements 0.495 cm. The mean change in CD4 count from pre-ART to 63, 123, and 243 months was 71, 89 and 153 cells/ L, respectively. In univariate analysis, higher albumin was associated with a smaller increase in CD4 count from pre-ART to 6 months post-ART (estimate

17.8 cells/ L per g/dL, p=0.03), but not at 12 or 24 months post-ART. Thus for example, those with 4.0 g/dL albumin gained on average 17.8 fewer CD4 cells/uL compared to those with 3.0 g/dL of albumin. FFM was also inversely associated with change in CD4 count at 6 months (6.7 cells/ L per kg/m2, p=0.03, respectively), but not at 12 or 24 months. For example, those with an adjusted FFM of 18.1 kg/ m2 gained 6.7 fewer CD4 cells/uL from pre-ART to 6 months post-ART compared to those with 17.1 kg/ m2 FFM. BMI, fat, and skinfold measurements were not associated with change in CD4 count at any follow up time.
In multivariate analysis after adjustment for covariates, no nutritional variables were associated with a change in CD4 cent count from pre-ART to 6, 12, or 24 months post-ART. Reflecting in part the regression to the mean phenomenon, higher CD4 count prior to initiation of ART was a consistent predictor of lower increase in CD4 count from pre-ART to each post-ART follow up time (estimate 20.52, -23.30, and 29.05 cells/ L, per 100 cells/l higher CD4 preART, respectively for 6, 12, 24 months, p<0.0001 for each).
CONCLUSION: In univariate analysis, higher FFM and albumin were associated with a smaller increase in CD4 count from pre-ART to 6 months, but not 12 or 24 months post-ART. However, these results did not persist in multivariate analysis at 6 months after adjustment for traditional predictors of response to ART. No marker of nutritional status predicted change in CD4 count from pre-ART to 6, 12, or 24 post-ART months in multivariate analysis.
These results show that poor pre-ART nutritional status, measured by BMI, adjusted fat, adjusted FFM, albumin, and skinfolds does not preclude a good response to ART. The associations, of higher FFM and albumin with a smaller post-ART CD4 increase seen in univariate analysis, likely reflect that these were markers of severe illness, and thus these were not significant in multivariate analysis. Low BMI, fat, FFM, albumin, and skinfolds can be associated with severe illness, and these markers should be fully investigated and interpreted with caution in further nutritional analyses.
ASSESSING PROVIDER KNOWLEDGE OF A HERNIATED LUMBAR DISC: ARE SPECIALISTS BETTER INFORMED THAN PRIMARY CARE PHYSICIANS? Sandra Feibelmann 1; Steven J. Atlas 1; KarenR. Sepucha1. 1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 10740)
BACKGROUND: Health care providers engaging in shared decision making with their patients need to be well-informed about the relevant condition and available treatment options and outcomes. Primary care physicians (PCPs) see patients with a variety of conditions that are often initially managed by the PCP but may eventually require specialty referral. We sought to compare PCP and specialist knowledge about a herniated lumbar disc (HD).
METHODS: Providers were identified through the American Medical Association physician master file. The HD survey was mailed to 100 primary care or internal medicine providers and 100 specialists in neurological surgery, orthopedic spine surgery, physical medicine and rehabilitation, and pain medicine. Mailed surveys included 21 knowledge items covering the benefits and risks of surgery and non-surgical treatment options for HD. We determined what proportion correctly answered each item and compared results of PCPs and specialists. RESULTS: Among 182 eligible participants, 97 providers completed the survey (53% response rate), 22 (23%) PCPs and 74 (77%) specialists. Their average age was 51 (SD 9.3), 83% were White, and they were practicing on average for 20 years (SD 9.8). PCPs had more years of practice than specialists (23 [SD 10.4] versus 18.5 [SD 9.4], p=.04).
Specialists saw more patients with HD, median annual volume of 200 (quartiles 97.5, 400) for specialists compared to 20 (quartiles 7.75, 52.5) for PCPs. Overall, respondents correctly answered 71% of survey items with specialists more likely to correctly answer items than PCPs (73% vs. 63%, p=.008). More specialists knew that pain caused by a herniated disc usually gets better without surgery (93% specialists vs. 73% PCPs, p=.02). More specialists also understood that surgery provides faster relief from pain (81% specialists vs. 54.5% PCPs, p=.02) and that after five years both surgery and non-surgical treatments provide similar pain relief (76% specialists vs. 41% PCPs, p=.003). Specialists were more likely to know the rate of a serious complication (82%

vs. 59%, p=.03). A majority of PCPs and specialists understood that exercise or staying active (91% vs. 90.5%, p=.62)), physical therapy (91% vs. 95%, p=.42), over-the-counter pain medicine (91% vs. 99%, p=.13), and cortisone shots into the back (91% vs. 97%, p=.22) help some patients relieve their HD pain. Less than half of providers knew how many patients would have the same or more back or leg pain after surgery (41% PCPs vs. 26% specialists, p=.13).
CONCLUSION: In this sample, specialists who treat herniated disc patients were more informed about the benefits and risks of HD treatments compared to PCPs. It is challenging for PCPs to remain knowledgeable about all relevant information, especially when patient volume for a particular condition is low. Decision aids and other materials may be useful to support PCPs in educating patients about treatment options for a HD.
DECISION SUPPORT AND INDIVIDUALIZED DECISION MAKING FOR COLORECTAL CANCER SCREENING IN THE ELDERLY CarmenL. Lewis 1; Christopher P. DeLeon 1; Michael P. Pignone 1; Carol E. Golin1. 1University of North Carolina - Chapel Hill, Chapel Hill, North Carolina. (Tracking ID # 10741)
BACKGROUND: Individualized decision making with providers about colorectal cancer (CRC) screening is recommended for adults age 75 and older because the potential net benefit of screening decreases with increasing age and co-morbidity. However, little is known about older patients preferences about CRC screening or the individualized decision making process. The purpose of this study was to provide decision support then examine physicians and patients perceptions of CRC screening and assess visit outcomes regarding CRC screening. METHODS: We recruited a convenience sample of 6 physicians and their patients who were age 70 and older, not up to date with CRC screening, and were scheduled for an upcoming appointment. Prior to the visit, we provided patients with a decision support booklet targeted to elderly patients. Physicians were given a bar graph showing life expectancy estimates divided by quartiles of health state and targeted to the patients age and gender. Patients responded to questions about their screening preference (prefer screening, prefer not to get screening or unsure) prior to decision support and after decision support but prior to their visit. After the visit, patients responded to 5 point Likert scale about their perceptions of decisional balance between the risks and benefits of screening. After the visit, physicians also responded to 5 point Likert scale about their perceptions of decisional balance in this patient and whether it was likely that screening would prolong the patients life. We analyzed audiotapes of the visit to determine visit outcome, specifically whether CRC screening was discussed and if a decision about screening was made.
RESULTS: Prior to decision support, 8 of the 20 patients preferred to undergo screening, 3 preferred no screening and 9 were unsure. Post decision support, 10 patients changed their screening preferences resulting in 6 who preferred screening, 9 preferred no screening, and 5

were unsure. After the visit, 12 patients thought the benefits outweighed the risks, 5 thought they were about the same, and 2 thought risks outweighed the benefits, while physicians responded that for 11 patients benefits were greater than risks, for 7 they were about the same, and 2 the risks were greater than the benefits. 11 physicians thought that screening would likely prolong the patients life, 3 reported it unlikely, and 6 assessments were neutral. Audiotapes revealed 8 visits with no discussion, 7 visits in favor of screening, 5 visits where screening was discussed but the decision was deferred, and no decisions were made to discontinue screening. The patients post decision support preference was not associated with the visit outcome (p=0.443) or the patients perception of decisional balance (p=0.135). However, the visit outcome was associated with the physicians perception of benefit (0.015), but not with physician decisional balance (p=0.62).
CONCLUSION: Patient decision support changed patient CRC preferences but these preferences do not appear to influence visit outcomes in this small sample. Perceived decisional balance was in favor of screening for both physicians and patients. Physicians perceptions of benefit may influence the individualized decision

making for older patients, although additional research is needed to confirm these findings and determine screening outcomes.

IMPACT OF STUDENT-RUN CLINICS ON PRECLINICAL STUDENTS SOCIOCULTURAL AWARENESS AND INTERPROFESSIONAL ATTITUDES: A PROSPECTIVE COHORT ANALYSIS Leslie C. Sheu 1; CindyJ. Lai 2; Anabelle D. Coelho 2; Lisa Lin 2; Patricia Zheng 2; Patricia Hom 2; Vanessa Diaz 2; Patricia S. OSullivan2.
1UCSF, San Francisco, California;
2University of California, San Francisco, San Francisco, California. (Tracking ID # 10742)

BACKGROUND: Descriptive studies have suggested that student-run clinics (SRCs) may positively impact preclinical students sociocultural and interprofessional attitudes which relate to how they may provide care in the future. However, rarely have studies included students from multiple professions, previously validated instruments, or a control group. At our health professions campus, first-year students from the Schools of Medicine, Nursing, and Pharmacy can elect to participate in one of three SRC electives, each focusing on a specific underserved population: Latino/Latina community, Asian/Pacific Islander immigrants, and the urban homeless population. In this study, we used validated measures to explore the impact of these SRCs on preclinical students sociocultural and interprofessional attitudes as compared to those who did not participate in SRCs.

METHODS: Using a pre-post control group design at the beginning and end of the academic year, we conducted a prospective cohort study involving first-year health professional students who did or did not participate in SRCs. We used two validated measures both using 5-point Likert scale for item ratings: 1) Sociocultural Attitudes in Medicine Inventory (SAMI), consisting of a 26-item questionnaire evaluating exposure to sociocultural attitudes and perceptions of influence of sociocultural background in physician/patient/health issues; and 2) Readiness for Interprofessional Learning Survey (RIPLS), a 19-item questionnaire measuring teamwork and collaboration, professional identity, and roles and responsibilities. The survey also included basic demographic information and open-ended questions for clinic participants to reflect on their experiences working with underserved populations and with other health professional students. All matching surveys were included in the statistical analysis. Descriptive statistics for all scales were generated in the two measures, and we conducted an analysis of covariance, using the pre-scores as the covariate, with two main effects, participation in SRCs and health professional school. The analysis was repeated for each dependent variable, which were the subscales for SAMI and RIPLS. The level of significance was set at 0.05. Qualitative analysis of open-ended responses was performed and consensus reached through discussion.

RESULTS: Of all students, 77% (274 of 358) completed the post-survey, with 68% (n=182) having matching pre-post surveys. First-year students held positive attitudes in both sociocultural and interprofessional domains at baseline and at the end of the year. There were no significant differences in context awareness based on SRC participation (p=0.53) or school (p=0.09), and no significant difference in sociocultural awareness (p=0.32 for SRC participation, p=0.06 for school). Students interprofessional attitudes were not different based on SRC involvement for any scale (p=0.385 for Team subscale, p=0.975 for Identity subscale, 0.285 for Role subscale). When analyzed by professional school, nursing students held more favorable interprofessional attitudes, regardless of SRC participation (p=0.006 for Team subscale, p=0.015 for Identity subscale, p=0.225 for Role subscale). No interaction effects were significant. In the qualitative analysis, 99% reported reinforced or increased commitment to working with the underserved, noting improved insight into health disparities and career choices. Forty percent reported that their experiences made a positive impact on their interprofessional attitudes.

CONCLUSION: In this study designed to rigorously evaluate the effect of SRC participation on two critical variables, we found no differences in sociocultural or interprofessional attitudes after adjusting for students baseline attitudes. However, given the highly positive scores on the SAMI and RIPLS at baseline, lack of further improvement in scores was not surprising; students still perceived benefits in their sociocultural and

interprofessional attitudes, suggesting that learning about these issues may be more tacit. Such positive experiences in SRCs may have other effects not examined in this study.

PHARMACIST INTERVENTION FOR LOW LITERACY IN CARDIOVASCULAR DISEASE (PILL-CVD): A RANDOMIZED CONTROLLED TRIAL Sunil Kripalani 1; Christianne L Roumie 2; Anuj K Dalal 3; Courtney Cawthon 1; Alexandra Businger 3; Svetlana Eden 1; Ayumi Shintani 1; Ileko Mugalla 1; Terry A Jacobson 4; Kimberly J Rask 9; Viola Vaccarino 9; Tejal K Gandhi 3; David W Bates 3; Mark V Williams 5; Jeffrey L Schnipper3. 1Vanderbilt University, Nashville, Tennessee ; 2VA Tennessee Valley Geriatric Research Education Clinical Center, Nashville, Tennessee ; 3Brigham and Womens Hospital, Boston, Massachusetts ; 4Emory University, Atlanta, Georgia ; 5Northwestern University, Chicago, Illinois . (Tracking ID # 10745)

BACKGROUND: Serious medication errors (SMEs) are common after hospital discharge and include preventable or ameliorable adverse drug events (ADEs), as well as potential adverse drug events (pADEs) due to medication discrepancies or non-adherence. The Pharmacist Intervention for Low Literacy in Cardiovascular Disease (PILL-CVD) study was a randomized controlled trial to determine the effect of an educational and behavioral intervention on the incidence of SMEs after discharge. METHODS: Patients hospitalized with acute coronary syndromes or acute decompensated heart failure were enrolled in the trial. The intervention consisted of pharmacist-assisted medication reconciliation, inpatient pharmacist counseling, low-literacy adherence aids, and tailored telephone follow-up beginning 14 days after discharge. The primary outcome was the incidence of SMEs during the first 30 days after hospital discharge. Secondary outcomes included the incidence of preventable or ameliorable ADEs, as well as pADEs. We computed the risk ratio (RR) and 95% confidence interval (CI) of events in the

intervention group vs. the control group using negative binomial regression.

RESULTS: Among 851 participants, 426 (50.1%) experienced >=1 SME, 256 (30.1%) had >=1 ADE, and 253 (29.7%) had >=1 pADE. The intervention did not significantly alter the number of SMEs (RR=0.92, 95% CI 0.77 to 1.10) or ADEs (RR=1.09, 95% CI 0.86 to 1.39). Intervention patients tended to have fewer pADEs (RR=0.80, 95% CI0.61 to 1.04), p=0.09. Post-hoc analyses stratified by site showed that at the site without information technology-assisted medication reconciliation previously in place, the intervention significantly reduced pADEs (RR=0.69, 95% CI 0.50 to 0.96).

CONCLUSION: A health-literacy sensitive, pharmacist-delivered intervention did not significantly reduce SMEs after hospital discharge. This type of intervention may reduce pADEs at hospitals without robust medication reconciliation programs.

TRENDS IN U.S. CORONARY REVASCULARIZATION PROCEDURES: 20012008 Peter W. Groeneveld 1; Daniel Polsky 1; Feifei Yang 1; Lin Yang 1; Gina Pugliano 1; Andrew J. Epstein1. 1University of Pennsylvania, Philadelphia, Pennsylvania. (Tracking ID # 10746)

BACKGROUND: Coronary revascularization is among the most common and most costly hospital-based major interventional procedures performed in the United States. It is uncertain how new revascularization technologies, new published evidence from clinical trials, and updated clinical guidelines during the past decade have influenced the national volume of all coronary revascularizations as well as the proportion of revascularizations that are coronary artery bypass grafting (CABG) surgeries. The objective of this study was therefore to examine national time trends in the volume and type of coronary revascularization procedures during 20012008.

METHODS: We used the Agency for Healthcare Research and Qualitys Healthcare Cost and Utilization Project/Nationwide Inpatient Sample (NIS), a complete set of hospital discharge claims from a stratified random selection of approximately 20% of U.S. hospitals, to estimate the total number of CABG surgeries and percutaneous coronary interventions (PCI) performed annually from 2001 to 2008, as indicated by procedure codes recorded on these claims. We then used Medicare claims to estimate the annual volume of outpatient

PCI procedures by calculating the annual ratio of outpatient to inpatient PCI procedures recorded on Medicare outpatient and inpatient facility claims, and applying this ratio to the inpatient PCI counts reported in the NIS. We tested time trends in proportions (e.g., CABG as a percentage of all revascularizations) with the Cochran-Armitage test, and we tested time trends in count data with negative binomial regression models. RESULTS: The annual volume of coronary revascularizations in the U.S. decreased from 1.18 million procedures per year in 2001 to 1.11 million procedures per year in 2008, a 6% decrease (p=0.02). The annual national CABG volume decreased steadily by 34%, from 371,700 procedures per year (32% of all revascularizations) in 200102 to 246,800 procedures per year (22% of all revascularizations) in 200708 (p<0.001), but PCI volume increased during the same interval from 808,000 procedures per year in 200102 to 864,800 procedures per year in 200708, a 7% increase (p=0.04). The estimated number of non-federal hospitals providing CABG increased from n=1,060 in 2001 to n= 1,200 in 2008 (p=0.002). The average CABG caseload per hospital declined by 39% (p<0.001), and the estimated number of hospitals providing fewer than 100 CABGs per year increased from n=140 in 2001 to n=320 in 2008 (p<0.001).
CONCLUSION: There was a 34% decline in CABG and a concurrent 7% increase in PCI for the treatment of coronary artery disease in the United
States during the past decade. This shift in revascularization practice patterns may indicate increasing preference by physicians and/or patients for PCI rather than CABG for the interventional treatment of coronary artery disease. It is uncertain whether this marked reduction in CABG utilization reflects increasing adherence to evidence-based guidelines for the use of CABG, or alternatively indicates increasing underuse of CABG for the treatment of those coronary artery disease patients (i.e., triple-vessel disease or left main disease patients) for whom CABG has demonstrably better outcomes than PCI.
CROSSING QUALITY CHASM: PRIMARY CARE FROM THE PERSPECTIVE OF HOMELESS PATIENTS AND THEIR CAREGIVERS Stefan Kertesz 1; David Pollio 2; Kay Johnson-Roe 3; Jocelyn Steward 3; Allison Borden 3; Theresa Kim 4; Erin Stringfellow 5; John Andrew Young 3; Cheryl Holt6. 1Birmingham VA Medical Center, Birmingham, Alabama ; 2University of Alabama, Tuscaloosa, Maryland ; 3Birmingham VAMC, Birmingham, Alabama ; 4Boston Medical Center, Boston, Alabama ; 5Boston Health Care for the Homeless, Boston, Alabama ;
6University of Maryland, Baltimore, Alabama. (Tracking ID # 10749)
BACKGROUND: A patient-centered medical home should address the priorities of the patients it seeks to help. For patients who have been homeless, these priorities may not be captured by standard primary care quality measures. We interviewed homeless patients and expert providers to better understand aspects of quality relevant to homeless primary care, as part of a project to develop a future patient-reported survey. METHODS: Thirty-six homeless patients from 2 cities were interviewed (28 male, 8 female; 22 veterans, 21 >1 year homeless). Interviews also included 22 nationally-selected expert providers (8 MDs, 7 nurses, 7 other). A semistructured interview queried 8 quality-related constructs drawn from Institute of Medicine (IoM) reports on primary care and quality. Interviews were audiotaped and transcribed. Two parallel analyses were used, a thematic analysis within existing IoM constructs, and an open-coded analysis for potential new constructs. Multiple coders were used, and acceptable inter-rater reliability achieved. Three new constructs emerged on preliminary review: Substance Abuse/Mental Illness, Homeless-Specific Needs, and Trust/Respect. A multidisciplinary team reviewed transcripts to identify 5 to 15 themes per construct.
RESULTS: Among 11 constructs, several themes distinctive to homeless care emerged. Examples:Under Patient Control, patients embraced some aspects of control (e.g. choice of provider) but also asserted limits on control (Im an addict!.. See if I had total control of what my doctor didI [would go out] and relapse and it would be ugly).
Under Shared Knowledge, potential misuse of the electronic record was referenced, as was the need for candid, dialogic communication (For you to sit with a doctor that dont even wanna speak to you, or dialogue

with you in no type of way, he just wanna look at youThats sad, thats pitiful.)
Under Homeless-Specific Needs, providers addressed competing priorities (shelter, food, etc), and the need to counteract stigma (Theyre so invisible anyway and feel such low self-esteem thatIts not even the straw that broke the camels back, its just, its F Y.).
Under Trust/Respect, patients and providers spoke about interpersonal comfort between patient and provider, and the importance of confidentiality (Trust means to me that I have no fear that what I say to him is going to get back to me through a third source, without me okaying it with him).
CONCLUSION: Patients and providers familiar with homelessness offer a nuanced understanding of IoM priorities such as patient control and shared knowledge while highlighting concerns regarding stigma, trust

and respect. Design and measurement of the patient-centered medical home requires specialized consideration if it is to effectively serve vulnerable subpopulations like the homeless.
PRIMARY CARE PROVIDERS ATTITUDES AND EXPERIENCES WITH ONLINE WEIGHT CONTROL PROGRAMS Kevin O Hwang 1;
Heather Stuckey 2; Monica Chen 1; Jennifer Poger 2; Samuel Forjuoh 3; Christopher Sciamanna2. 1The University of Texas Medical School at Houston, Houston, Texas ; 2Penn State College of Medicine, Hershey, Pennsylvania ; 3Texas A&M HSC College of Medicine, Scott &White Healthcare, Temple, Texas . (Tracking ID # 10766)
BACKGROUND: Online weight control programs (OWPs) help overweight and obese individuals lose weight. Partnerships between OWPs and primary care providers (PCPs) could yield substantial public health benefits, in which each party provides services according to its own strengths. PCPs note that they lack competence in helping their patients lose weight and that their patients lack access to programs with low out of pocket costs. Despite their potential to address needs of PCPs and patients, OWPs have not been integrated into the primary care setting. This study sought to learn about PCPs attitudes and experiences with OWPs. Such knowledge is critical if OWPs are to be successfully integrated into primary care.
METHODS: We conducted 6 focus groups with 3 to 8 internal medicine and family medicine PCPs at 3 centers (n=32). Discussions were recorded and transcribed verbatim. Transcripts were reviewed iteratively for recurring themes. Open-ended questions addressed topics such as: referring patients to specialists, other professionals, community resources, and OWPs; characteristics of effective OWPs; and barriers to referring patients to OWPs.

RESULTS: When considering weight loss resources for their patients, the PCPs valued affordability, structure, familiarity, practicality, and educational content. PCPs personal and professional experience with OWPs was limited. Some PCPs referred patients to websites which provided basic information and aid in counting calories. PCPs perceived difficulty in identifying effective, evidence-based OWPs from among an extensive array of weight-related websites. They believed that effective OWPs would offer the following: structured behavioral program; accountability from other users and/or other staff; practical tips on how to initiate and maintain beneficial behaviors; and aid with decisions. They regarded information alone as inadequate to help patients lose weight. The PCPs felt that online discussions among users of OWPs should be monitored by experts for content and tone. Additionally, they welcomed the idea of receiving feedback from administrators of OWPs about their patients progress, especially if they could specify the amount and frequency of such feedback. The PCPs anticipated using the feedback as a framework for talking with patients about their weight loss efforts and for praising patients when weight loss was successful.
CONCLUSION: The features which PCPs desire can be found in existing OWPs or are technically feasible to implement. Researchers and OWP administrators need to collaborate to design and identify effective OWPs in

prospective studies. Reducing or eliminating costs to patients will likely encourage PCPs to refer patients to OWPs. Lastly, OWPs should work closely with PCPs to design flexible systems for sending feedback to the PCPs about their patients.

THE PREVALENCE OF CONFLICTS OF INTEREST AMONG GUIDELINE PANEL MEMBERS Jennifer Neuman 1; Deborah Korenstein 1; Joseph S Ross 2; Salomeh Keyhani1. 1Mount Sinai School of Medicine, New York, New York; 2Yale University School of Medicine, New Haven, Connecticut. (Tracking ID # 10767)

BACKGROUND: Conflict of interest (COI) among authors of clinical practice guidelines may adversely impact the objectivity of the recommendations issued. Over the past decade, scant research has examined this topic in the field of Internal Medicine. We sought to determine the frequency of COI among authors of clinical practice guidelines between the years 20002010.

METHODS: We conducted a retrospective study of authors of hyperlipidemia and diabetes guidelines, published between the years 2000 and 2010 in the US and Canada. We chose hyperlipidemia and diabetes as representative disease categories because of the high prevalence of both diseases in the population. Guidelines were identified through The National Guideline Clearinghouse, MDConsult, UpToDate, and the websites of organizations with a potential interest in these diseases. COI were defined in two ways: 1) as the direct compensation of a guideline author by a pharmaceutical company in the form of grants (including research), speakers fees, honoraria, etc., or 2) primary authorship (1st author) of a clinical trial funded by the a manufacturer of a drug used to treat the disease of interest in the guideline, in the two years prior to and the year of guideline publication. Direct compensation was determined by examining declarations of COI that were published within the guideline. Authors that declared no COI were further investigated through examination of publications via MEDLINE and through an internet search. Guidelines were categorized as government-sponsored versus other, year developed (before and after 2007), disease (hyperlipidemia versus diabetes) and country of origin (U.S. and Canada). We used descriptive statistics to characterize the prevalence of COI among authors and panel Chairs and used two-sampled tests of proportion to examine differences by guideline characteristics.

RESULTS: We identified 14 guidelines meeting our search criteria. These guidelines included 288 authors, representing 246 separate individuals. All guideline panels had at least one author with a COI. Overall, 55% (158/288) of authors were found to have COI. Among authors not reporting COI, 13% (20/150) had undeclared COI. Among Chaired guidelines, 60% (6/10) of Chairs had COI. Government-sponsored guideline panels had significantly fewer authors with COI than non-government-sponsored panels (71% vs. 20% P less than0.001), and COI was more prevalent among Canadian specialty organizations than U.S. specialty organizations (84% vs. 62%, p less than 0.01). We found an increased presence of COI in guidelines published after 2007 compared to those published prior (66% vs. 28%, p less than 0.001).

CONCLUSION: We found a high prevalence of COI, under-reporting of COI by guideline authors, and significant differences in the prevalence of COI between government and non-government-sponsored guidelines. Our finding that the majority of guideline authors and Chairs have COI, and that one out of eight authors did not report their COI raises concerns about the objectivity of these guidelines and the effectiveness of current disclosure practices. The guideline development process must be reformed to minimize conflicts of interest among authors to ensure the credibility and evidence-based nature of the clinical practice guidelines issued in the U.S. and Canada.

WILLINGNESS TO PAY (WTP) FOR WEIGHT LOSS COACHING: RESULTS FROM THE POWER TRIAL Reza Alavi 1; Lawrence Appel 1; Frederick Brancati 2; Jeanne Clark 1; Penny Mohr 3; Gail Daumit4. 1Johns Hopkins University, Baltimore, Maryland ; 2Johns Hopkins School of Medicine, Baltimore, Maryland ; 3Center for Medical Technology Policy, Baltimore, Maryland ; 4Johns Hopkins University, Rockville, Maryland . (Tracking ID # 10768)

BACKGROUND: With two thirds of American adults currently over-weight or obese, there is a pressing need for affordable evidence based weight-loss interventions. Efficacious medical or behavioral weight-loss programs are not routinely covered by insurance. Commercially-available programs do not have rigorous evidence supporting their efficacy and effectiveness, and insurance companies have been reluctant to cover such interventions. Improving the evidentiary base for weight loss interventions and understanding how patients value weight loss interventions by assessing their willingness to pay (WTP) is a critical step in translating findings from effectiveness trials into practice. Upon completion of a randomized controlled trial comparing an in-person behavioral intervention to a phone/email/web-based intervention for weight-loss, we studied participants WTP and the characteristics associated with WTP for continuing their weight loss interventions.
METHODS: POWER Hopkins is an on-going NHLBI-funded 24-month randomized clinical trial of weight loss with a self directed control arm, and two active intervention groups: 1) an in-person directed (IPD) group with individual and group in-person interventions plus web-based education and tracking support; 2) a call-center directed (CCD) group with similar interventions delivered by telephone, web, and email. At the end-of-study visit, we conducted in-person interviews of the IPD and CCD participants to assess their valuation of services received, double bound dichotomous-choice WTP, and likelihood to actually purchase these products. We used linear regression to examine the baseline characteristics (age, sex, income, race, education, and BMI) associated with WTP. RESULTS: Of the 234 adults who completed the trial to date, 206 (88%) completed the end of study WTP survey. Mean age was 57 years, 61% were women and 56.3% were White, mean BMI at baseline (2 years earlier) was 36.4 kg/m2, 33% had graduate or professional degrees, and 61% had annual family income >$75,000. 69.4% of participants were interested in continuing the intervention, and 46.6% were ready to actually sign up for the services they received in the next two months (Table). Participants thought their intervention was worth $70.9 (CI60.3-81.4), and they were willing to pay $49.6/month (CI 44.8-54.3). Multivariate analysis identified race as the only predictor of WTP: White participants reported mean WTP that was $18.2 (CI 8.0-28.3) less than African American participants.
CONCLUSION: After completing a two-year trial, the majority of participants in both groups were interested in continuing their multifaceted weight-loss interventions, and were willing to pay similar rates to other commercially available products. The surprising racial differences in WTP seen in this high SES group needs to be further examined when trial weight results are available. After a free or fully subsidized period, it might be reasonable to implement a direct to consumer or cost sharing mechanism to better translate effective evidence-based weight loss interventions into practice.

DO FINANCIAL INCENTIVES FOR GUIDELINE ADHERENCE IMPROVE CARE OF HYPERTENSION IN THE PRIMARY CARE SETTING? A MULTI-SITE RCT

Laura A. Petersen 1; Kate Simpson 1; Le Chauncy Woodard 1; Kenneth Pietz 1; Tracy Urech 1; Meghan Z. Lutschg 1; Sylvia J. Hysong 1; Douglas Conrad 2; Jochen Profit 1; R. Adams Dudley3.
1VA HSR&D Center of Excellence Health Policy and Quality Program and Baylor College of Medicine, Houston, Texas ; 2Departments of Health Services and Finance and Business Economics, University of Washington, Seattle, Seattle, Washington ; 3Department of Medicine and Institute for Health Policy Studies, University of California, San Francisco, San Francisco, California . (Tracking ID # 10771)

BACKGROUND: Few data exist regarding the effectiveness of pay-for-performance programs as a tool to change provider behavior and improve quality of care, and some claim that financial incentives for quality are unnecessary and/or ineffective in motivating physicians to improve care. Using a cluster randomized controlled trial (RCT), we evaluated whether participants who receive financial incentives in addition to audit and feedback for their performance in delivering guideline-recommended hypertension (HTN) care improved the quality of HTN care in the primary care setting.
METHODS: Eighty-three primary care physicians and 45 non-physician health care staff members from 12 VA primary care clinics in 11 states enrolled in a 20-month cluster RCT designed to assess the effectiveness of

financial incentives in improving adherence to guideline-recommended HTN care as outlined in the Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 7). Participants at each hospital were cluster-randomized to one of four study arms: (1) physician-level incentives; (2) practice group-level incentives; (3) combined physician- and group-level incentives; or (4) control. Participants received an educational session about HTN management. At the end of each of five 4-month study periods, all participants received audit and feedback on their performance. Intervention-arm participants received monetary rewards based on their use of guideline-recommended antihypertensive medications and the proportion of their patients who achieved JNC 7 blood pressure (BP) goals or received appropriate treatment in response to an elevated BP reading. Appropriate treatment included prescribing a new or increasing the dose of a current medication, prescribing a lifestyle modification for patients with Stage 1 HTN, or a follow-up visit with a controlled BP reading. We included data from the 77 physicians who participated for at least two performance periods in a repeated measures model with covariates for arm, performance period, an arm*performance period interaction, and an indicator of whether or not the provider had reached the ceiling value for that measure. We also performed backwards elimination on a maximal model including the above covariates as well as those with a scientific or statistical

Table 1:

association with the outcome. We evaluated the arm*performance period interaction to assess the effectiveness of the intervention.

RESULTS: Average total payment over the 20 month study period for a physician in the individual arm was $2,570. The rate of improvement in proportion of patients achieving BP control or receiving appropriate clinical response to uncontrolled BP from one performance period to the next was 1.5 percentage points greater for physicians in intervention arms than for physicians in the control arm ($p<0.01$). This means that, on average, for two study physicians with panel sizes of 1,000 patients each, the physician in the intervention arm would have 45 more patients achieving BP control or appropriate response to uncontrolled BP after one year of exposure to the intervention, whereas the control arm physician would have only three more patients meeting this measure after the same period. After controlling for the gender and average age of a physicians patients and whether a physician practiced at a teaching hospital, this relationship remained significant ($p<0.01$). When the four study arms were compared, participants in group incentive arms showed no statistically significant differences from control arms.

CONCLUSION: Patients of physicians who received modest financial incentives in addition to audit and feedback for delivering guideline-recommended HTN care had greater rates of improvement in BP control or receiving an appropriate clinical response to uncontrolled BP than patients of physicians who received audit and feedback only. However, incentives targeted at individuals appear to be more effective than incentives targeted at groups. These results suggest that, if properly designed, performance-based health care payment models could improve the quality of health care. Our ongoing work is assessing whether incentives have unintended effects on patients or the health care delivery system.

READMISSION RISK MODELING: A SYSTEMATIC REVIEW Devan Kansagara 1; Honora Englander 2; Amanda Salanitro 3; David Kagen 4; Cecelia Theobald 3; Sunil Kripalani3. 1Portland VA Medical Center, Oregon Health and Science University, Portland, Oregon ; 2Oregon Health and Science University, Portland, Oregon ; 3Vanderbilt University, Nashville, Tennessee ; 4Portland VA Medical Center, Portland, Oregon.
(Tracking ID # 10779)

BACKGROUND: Easily deployed risk models able to accurately identify those at high-risk for hospital readmission could help target transitional care interventions to the most appropriate patients. In addition, the

utility of readmission rates as a quality metric depends on accurate prediction of the readmission rate expected in a given population. We performed a systematic review of risk prediction models for hospital readmission. METHODS: We searched Ovid MEDLINE, CINAHL, and the Cochrane Library (Central Trial Registry, Systematic Reviews, and Abstracts of Reviews of Effectiveness) from database inception through June 2010 for English-language studies of readmission risk prediction models for adult medical patients. We had searched reference lists of reviews and relevant articles. Each full-text article was independently assessed by two reviewers for inclusion. We only included models tested in both a derivation and validation cohort. RESULTS: From 6089 abstracts, we reviewed 141 full-text articles. Thirty-two articles examining twenty risk models met inclusion criteria. Most of these modeled the risk of all-cause readmissions ranging from 30 days to one year post-discharge. Only one study specifically distinguished potentially preventable readmissions. Most models relied on readily available administrative data, though 8 of 20 models did incorporate primary data from surveys or chart review. The ability of
most models to accurately distinguish high from low readmission risk was poor to fair (11/13 models with available data reported a c-statistic of <0.70; range 0.600.83). Almost all models (19/20) included comorbidity variables and most (17/20) included utilization variables such as prior hospitalization. Most models examined basic socio-demographic factors such as age, sex, and race, but only seven examined other patient characteristics such as social support, behavioral risks, and depression. Prior hospitalization was consistently among the factors most predictive of readmission. However, given the differences in populations and risk factors examined, it is unclear which other risk factors are consistently associated with readmission risk. CONCLUSION: Many statistical models predicting readmission risk have been evaluated, but their predictive ability is modest. This may reflect the very complexity of factors that contribute to readmission risk. Many models use administrative data and could be readily deployed at a health system level, but limited accuracy may temper their utility as quality metric tools. Moreover, potentially important clinical and socio-demographic variables are often overlooked. Future studies should assess the value of modeling patient characteristics that could be targeted by interventions such as health literacy, depression, and medication adherence.
SERVICES AVAILABLE TO LATINO PATIENTS WITH DIABETES AT HEALTH CENTERS ACROSS THE MIDWEST Arshiya A. Baig 1; Cara Locklin 1; Amanda Campbell 2; Cynthia T. Schaefer 3; Loretta Heuer 4; Marla C. Solomon 1; Quinn T. Michael 1; Martin Vargas 5; Deborah L. Burnet 1; Marshall H. Chin1. 1University of Chicago, Chicago, Illinois ;
2MidWest Clinicians Network, Inc., Lansing, Michigan ; 3University of Evansville, Evansville, Indiana ; 4North Dakota State University, Fargo, North Dakota ; 5Community Action Partnership of Western Nebraska, Gering, Nebraska. (Tracking ID # 10782)
BACKGROUND: Type 2 diabetes disproportionately affects the growing Latino population and causes a high burden of disease. Many Latino patients with diabetes have limited socioeconomic resources, and thus health centers play a crucial role in caring for them. In this study, we assess the availability of services provided to Latino patients with diabetes at health centers across the Midwest and whether services vary by proportion of Latinos with diabetes seen at the centers. METHODS: We conducted a survey of providers that treat patients with diabetes at Federally Qualified Health Centers affiliated with the MidWest Clinicians Network (MWCN). A survey was mailed to 1475 providers at 99 health center sites across 10 Midwestern states. Providers included certified diabetes educators, certified medical assistants, dietitians, health educators, licensed practical nurses, physicians, physician assistants, registered nurses, advanced practice nurses, and social workers. Providers were asked about the access to: 1) different types of providers; 2) language services; 3) culturally-tailored diabetes services; 4) expanded clinic hours; and 4) community outreach services at their sites. Health center sites were categorized as low density (LD) if <25% of their diabetes patient population was Latino or high density (HD) if >25% their diabetes patient population was Latino. RESULTS: We received responses from 622 providers (47% adjusted response rate) at 87 sites (88%) from all 10 states with an average of 6 respondents

per site. Of all respondents, 247 (39%) were physicians, 131 (17%) were advanced practice nurses, and 60 (10%) were physician assistants. 266 (43%) providers stated they worked in HD sites. Table 1 describes results by high density and low density site providers. Cluster analyses by site did not show any difference in the outcomes listed. CONCLUSION: Health center sites serving a high density Latino patient population with diabetes offered many specialized services such as Spanish-

speaking providers, on-site interpreters, culturally tailored diabetes programs and community outreach for their patients. However, there are many opportunities for improvement related to subspecialty access, language services, and culturally tailored programs at both HD and LD sites.

Table 1. Services to patients by site density

THE ASSOCIATION OF VARYING LEVELS OF ENGLISH ABILITY WITH GLUCOSE CONTROL AMONG LATINOS WITH DIABETES Arshiya A. Baig 1; Cara Locklin 1; Edward Foley 2; Bernard Ewigman 1; David O Meltzer 1; Elbert S Huang1. 1University of Chicago, Chicago, Illinois; 2Macneal Hospital, Berwyn, Illinois. (Tracking ID # 10785)

BACKGROUND: English speaking ability may impact receipt of diabetes care and glucose control among Latinos. Most diabetes studies have treated ability to speak English as a dichotomous variable despite the fact that there are many levels of English speaking ability. As a result, it is unclear how varying levels may be associated with glucose control

among Latinos. Our main objective was to assess the association of English speaking ability with glucose control among Latinos with diabetes.

METHODS: We analyzed a subset of 167 Latino adults with diabetes from a cross sectional survey of 676 adults with type 2 diabetes recruited at clinics in the Chicago area from May 2004 to May 2006. The main outcome of interest was inadequate glucose control, defined as a glycosylated hemoglobin (HbA1c) >=7.0%. The main exposure of interest was English speaking ability, which was categorized as a series of indicator variables self-reported as speaking English very well (referent), well, not very well, or not at all. Adjusted analyses accounted

for age, gender, educational attainment, annual income, health insurance status, duration of diabetes in years, being born in the U.S. and number of years in the U.S.

RESULTS: In the sample, 38% reported speaking English very well, 21% reported speaking well, 26% reported speaking not very well and 14% said they did not speak English at all. Latinos who reported speaking English very well were more likely than the other groups to be younger, have graduated high school, and to have been born in the U.S. (all ps <0.01). Mean A1c was 8.01.9% for Latinos who spoke English very well,6.01.1% for those who spoke well, 7.41.5% for those who spoke not very well, and 8.61.9% for those who spoke no English. In adjusted analyses, Latinos who spoke English well were less likely to have an HbA1c <7.0% (OR=0.31, 95% CI 0.10-0.96) compared to those who spoke English very well. The odds of having inadequate glycemic control did not differ statistically for those who reported speaking English not very well (OR=0.69, 95% CI 0.19-2.44) or not at all (OR=1.55, 95% CI0.34-7.07) compared to those who spoke English very well. CONCLUSION: English speaking ability has a variable association with glycemic control in Latino patients with diabetes. High English fluency may reflect acculturation and adoption of poor lifestyle habits while inability to speak English may reflect increased barriers to care and lack of access to resources for diabetes. Further studies are needed to elucidate the mechanisms by which language affects glucose control.

WEBSITE FOR AT-RISK ALCOHOL USE: HOW TO MAKE IT VISIBLE AND FOR WHOM? Nicolas Bertholet 1; Myriam Rege Walther 2; Bernard Burnand 2; Jean-Bernard Daeppen1. 1Alcohol Treatment Center, Lausanne

University Hospital, Lausanne, N/A; 2Health Care Evaluation Unit, University Institute of Social and Preventive Medicine, Lausanne, N/A. (Tracking ID # 10794)

BACKGROUND: Websites providing information and tailored feedback for at-risk alcohol use are increasingly used to reach a large population that does not necessarily access primary care practices. Such websites need to target individuals with at-risk alcohol use and to be visited. METHODS: We developed a website offering general information on alcohol use and its consequences, screening, and brief intervention with tailored feedback. The website is in French. To increase its visibility, we conducted a media campaign in the French part of Switzerland. We assessed the characteristics and satisfaction of the users. To qualify the impact of the media campaign, we recorded the geographical provenance of the users.

RESULTS: Between July 15 and November 14 2010, 14938 visitors accessed the website and 86% completed the screening and received tailored feedback. General information pages represented 23% of all the visited pages. Most users were male (67%), mean age (SD) was 36.5(13.6); 34% of men and 38% of women reported weekly risky use (>14 drinks for men, >7 for women), 54% of men and 30% of women reported binge drinking (>6 drinks/occasion) at least once a month. Of the 56% people with risky use (either weekly risky use, binge drinking once a month or both), 67% envisioned change after receiving the feedback. Among those (n=976) who completed the satisfaction survey, 88% said the website provided useful information, and 79% that they could recommend it to a friend. Most visits (84%) came from Switzerland. CONCLUSION: People may visit websites providing information and personalized feedback on alcohol use on their own, but a media campaign appear to increase largely the number of visitors. Our website seems to target the appropriate users since at-risk alcohol use was overrepresented among users compared to the general population, and satisfaction was high. Most at-risk drinkers envisioned change after their visit.

ACTIVATING PATIENTS TO IMPROVE GLYCEMIC CONTROL: THE REDUCING RACIAL/ETHNIC DISPARITIES IN DIABETES WITH COACHED CARE (R2D2C2) PROJECT Sherrie H. Kaplan 1; Dara H. Sorkin 1; John Billimek 1; Quyen Ngo-Metzger 1; Sheldon Greenfield1.

1University of California, Irvine, Irvine, California. (Tracking ID # 10795)

BACKGROUND: The Coached Care intervention, aimed at increasing patient involvement in treatment decisions, has been shown to improve the health outcomes of patients with chronic diseases. In order to assess its effectiveness in reducing disparities in diabetes care among diverse patient groups, we modified the intervention to use community-based coaches with diabetes drawn from outpatient clinics of a university teaching hospital. METHODS: We conducted a stratified, randomized controlled cluster trial at all 6 outpatient clinics of a university teaching hospital. We stratified by clinic and three ethnic groups: Non-Hispanic white, Mexican-American, and Vietnamese. Patients are randomized to enroll in either the Coached Care intervention or the control group and are followed for two years. Patients enrolled in the Coached Care intervention are each paired with an ethnically and linguistically matched coach, who meets with the patient for 20 minutes before every diabetes-related medical visit during the study period. The coaches, who themselves also have diabetes, were recruited from the community and trained to teach patients skills to negotiate treatment decisions with their providers. Patients randomized to the control group complete 20-minute standardized diabetes education sessions with a research assistant before each visit.

To date, 677 patients have been enrolled in the study. All study patients completed baseline and follow-up surveys. Other key study variables were collected from medical records, laboratory and administrative databases. The primary outcome was change in hemoglobin A1c from baseline to one-year follow-up. Multiple regression was used to test intervention effects on glycemic control over the observation period. RESULTS: To date, 288 patients (79% Mexican American, 8% Vietnamese, 13% Non-Hispanic white) have completed the one-year observation point. The majority of patients (53%) had a median annual household income below $20,000; 66% had limited proficiency in English. There were no significant differences between the Coached Care group (mean [SD]=9.1% [1.4%]) and control group (9.2% [1.6] %; p=.52) in baseline HbA1c values. At one

year, patients in the Coached Care intervention group had a significantly lower HbA1c (8.6% [1.8%]) compared to controls (9.2% [1.9%]; p<.05). This difference persisted after adjustment for baseline HbA1c, age, gender, race/ ethnicity, duration of diabetes and regimen intensity (adjusted mean difference [95%CI]=0.38[0.75,-0.02]; p<.05).
CONCLUSION: Coached Care appears to improve glycemic control in a socioeconomically and ethnically diverse patient sample. Further research will address whether for similar access to care, Coached Care is effective in reducing racial disparities.
CLINICAL MESSAGING &PRACTICE VARIATION: A 10 YEAR EXPERIENCE Bradley H. Crotty 1; Yonas S. Tamrat 1; Arash Mostaghimi 1; Charles Safran 1; Bruce Landon1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 10798)
BACKGROUND: Patient Portals, which offer secure electronic communication between patients and their providers, were first introduced in 2000. Despite patient interest, clinicians have been slow to adopt clinical messaging into their practices. Although the usefulness to patients of clinical messaging in terms of convenience is clear, large numbers of messages have the potential to burden busy physicians, who must triage and respond to each inquiry directly without additional compensation. The long-term trends of clinical messaging have not been

described. In this study, we report on the usage patterns of clinical messaging within a large health system that was among the first nationally to adopt this technology. In addition, we also examine whether use within primary care differs by practice setting. METHODS: We analyzed patient portal use over a ten-year period within a single academic health system. Clinical messages were defined as patient-initiated clinical correspondence sent to a physician or nurse practitioner, excluding appointment and prescription refill requests. We restricted the analysis to actively enrolled patients, defined as registered patients who had accessed the web portal within the preceding two years. We assessed trends in the number of actively enrolled patients, and message frequency per 100 actively enrolled patients as well as per provider. Analyses examining differences in clinical messaging by demographic and clinical characteristics using multivariate Poisson regression are currently underway. In preliminary analyses looking at usage patterns by practice setting, we analyzed 2010 data from three primary care practices with heterogeneous patient populations: an urban hospital-based practice, a satellite practice located in an underserved area, and a community health center serving primarily underserved patients. We analyzed the average number of messages/100 actively enrolled patients/month using the Kruskal-Wallis test. Analyses were performed using SAS 9.2 (Cary, NC). RESULTS: At the close of 2010, approximately 50,000 patients were active users of the patient portal across all participating practices within the health system. The number of clinical messages grew steadily along with total number of patients. (Figure 1) Over the ten-year period, providers saw a near doubling of messages, from 15.9 (SD 2.1) to 31.2 (SD 3.8) messages per month. (Figure 2) The average number of messages per 100 actively enrolled patients per month decreased initially over the first two years from37.2 (SD 3.0) in 2001 to 20.6 (SD 2.2) in 2003, and then stabilized at an average of 22.0 (SD 2.6) from 20042010. Among the subset of primary care practices, patient use of clinical messaging differed by the practice setting. The median number of clinical messages per 100 actively enrolled patient per month in 2010 was 21.5 (IQR 3.5) for the hospital-based practice, 17.4 (IQR 3.6) for the satellite practice in an underserved area, and5.9 (IQR 4.0) for the community health center (p<0.001). CONCLUSION: Patient portal registration and clinical messaging has steadily increased over the past decade. After starting at a relatively high level and decreasing over the first three years, the average number of clinical messages per user per month has remained relatively constant over the last seven years. The initial high volume may reflect an early-adopter effect for patients who were among the first to sign up for the patient-portal. Over the ten-year study period, the average number of messages per provider has nearly doubled as more patients per provider have become users of the portal. Within primary care, use of clinical messaging varied

widely by practice setting among actively enrolled patients.

A MOBILE HEALTH APPLICATIONS NEEDS ASSESSMENT AT A LARGE ACADEMIC INSTITUTION Ida Sim 1; Raymund Dantes1.
1University of California, San Francisco, San Francisco, California. (Tracking ID # 10803)
BACKGROUND: Mobile communication devices present opportunities to improve health and disease management by expanding interventions beyond the reach of traditional, practitioner visit-based care. Already, 17% of cell phone users have used their phone to access health or medical information, and 9% of cell phone users have an application that helps them track or manage their health. The vast majority of mobile health applications operate independently in closed silos that do not communicate with other applications or electronic health records.
At the University of California, San Francisco, a large, research-intensive health sciences public university and medical center, there is growing interest to establish a centralized infrastructure to support and encourage creation of mobile health applications for research projects as well as for clinical care. In this study, we sought to summarize the current experience of UCSF mobile health developers; and second, to assess the specific needs of future mobile health developers at UCSF, so that future campus-wide efforts can better support faculty, staff, and trainees in the development of new applications.
METHODS: We conducted a cross-sectional, mixed quantitative and qualitative web-based survey from August 29 to September 24, 2010 of all faculty, staff, trainees, and students of the University of California, San Francisco.
Survey questions were formulated and piloted with the input of key stakeholders, including current mobile health developers and campus administration.
Participants were solicited using a single email invitation jointly sent by the university provost and the chief information officer to all UCSF faculty, students, and staff. This includes approximately 24,000 people. Only email recipients with interest or experience in developing mobile health applications were asked to complete the survey. Participants received no financial or other material compensation. Participants were not required to answer every question. The survey began by asking whether the participant had current or prior experience developing mobile applications. Participants without prior experience were asked a total of 12 questions. Participants with prior mobile application experience were asked 9 additional questions about their experiences, for a total of 23 survey questions.
RESULTS: We received responses from 770 people, for an overall response rate of approximately 3%.165 respondents indicated that they were currently or had been previously involved with developing a mobile application for use with patients, research participants, trainees, or colleagues. 22 respondents had applications that had already been deployed, 21 had project prototypes, and 34 had projects under design. Common barriers encountered by developers included high initial costs, procuring funding, data security, and technical development.
Enthusiasm for mobile health development services was very high among hundreds of survey respondents. 515 (95%) respondents would consider or definitelyuse campus-based mobile health development services if they were available.
The intended functions of mobile health applications were diverse. The majority of respondents said their applications would be used for research (66%), patient care (62%), and health education (58%). Nearly half would use mobile applications for health monitoring (49%), and 42% would use applications for clinical teaching.

Respondents were also more interested in building applications for low socioeconomic status (SES) populations compared to middle or high SES populations (37% vs.
31% and 25%). Nearly one-third of respondents wanted to develop applications for low English or low health literacy populations. Respondents indicated they would like additional support in all steps of mobile application development, but more requested support in technical development (65%), building a user interface (59%), programming/coding (54%), and application testing/refinement (53%).
CONCLUSION: We discovered there are already at least 165 mobile health development projects at UCSF, with dozens of projects already deployed or in prototype stages.
We also discovered there are 515 UCSF community members who have mobile health ideas they would consider or definitely develop if support services were available. There was high enthusiasm for using mobile health applications for patient care, research, and health education. There was also significant enthusiasm for building applications for low SES, low English, and low health literacy populations.
To our knowledge, there is no other publically available survey of mobile health technologies at a similar academic institution.
This needs assessment survey of potential mobile health developers was designed to guide the development of mobile health development services at our institution. Based on our quantitative and qualitative results, we recommend that such services prioritize technical services, including programming and secure data management. These services should be flexible enough to assist in the creation of education, research, and patient care applications. The emergence of mobile health technologies is an unprecedented new technology that will have significant but still unpredictable effects on the future of patient care, medical research, and education. Academic institutions should consider which technical, consultative, and infrastructure services are needed to enable faculty, staff, and trainees to most effectively advance the use and science of mobile health.
IMPACT OF WORKLOAD ON PATIENT SAFETY AND QUALITY OF CARE: A SURVEY OF AN ONLINE COMMUNITY OF HOSPITALISTS Henry Michtalik 1; Peter J Pronovost 1; Brian Driscoll 2; Michael Paskavitz 3; Daniel Brotman1. 1Johns Hopkins University, Baltimore, Maryland; 2Quantia Communications, Waltham, Massachusetts. (Tracking ID # 10808)
BACKGROUND: Studies of the impact of provider workload on patient safety and quality of care have primarily focused on nurses and resident physicians, but not attending physicians. We examined the relationship between workload and patient safety and quality via a survey of an online community of Hospitalists.
METHODS: We electronically surveyed 890 self-identified Hospitalists enrolled in QuantiaMD.com, an online physician community which provides continuing medical education and a national discussion forum. Participants received a secure e-mail link to the online survey and were awarded $10 at completion. The survey queried physician and practice characteristics, workload, frequency of an unsafe census, and what a safe workload would be in his/her setting. Safe was defined as with minimal potential for error or harm. Physicians also rated the impact of average census on process and outcome measures using a Likert scale ranging from 1 (Never/Definitely Not) to 5 (Very Often/ Definitely).
RESULTS: Of the 890 physicians contacted, 506 (57%) responded. Five (1%) were excluded for not completing the survey. Physicians had an average age of 38.3 years (SD: 8.4) and were in practice for a median of 6 years [IQR: 3, 10]. The majority identified their primary practice area as adult (78%), pediatric (1%), or combined med/peds (2%) hospital medicine. Physicians practiced in an urban (46%),

suburban (43%), and rural (11%) setting and primarily as part of a community hospital (54%), academic teaching hospital (28%), or private group (12%). Forty percent of physicians reported that their typical inpatient census exceeded safe levels at least monthly and 36% of these reported a frequency greater than once per week. When the average actual workload was compared to the perceived safe workload, 40% of physicians exceeded their own reported safe level. Physicians reported that their patient load often (>4/5) led to incomplete

patient/family discussions (25%), ordering potentially unnecessary tests or procedures (22%), delaying admitting or discharging patients until the next shift or day (22%), cross-covering (20%) or caring (17%) for too many patients, worsened patient satisfaction (19%), poorer handoffs (18%), increased 30 day read-mission (14%), worsened overall quality of care (12%), failure to promptly act on critical findings (10%), and treatment errors (7%). With respect to adverse events, physicians reported that workload has likely (>4/5) caused transfers to higher levels of care (10%), morbidity/complications (7%), mortality (5%), and incident reports (6%).
CONCLUSION: Hospitalists currently report unsafe workloads that expose patients to poorer quality of care and adverse events. Forty percent of Hospitalists reported an unsafe workload at least monthly. Over 20% of Hospitalists reported workload has often caused incomplete patient discussions, unnecessary tests and procedures, admission/discharge delays, and excessive cross-coverage. Over 20% of Hospitalists also reported that workload has likely caused patient transfers, morbidity, or mortality. Hospitalist workload may be adversely affecting patient safety and quality of care and should be further explored.

INAPPROPRIATE TESTING FOR URINARY TRACT INFECTION IN HOSPITALIZED PATIENTS: AN OPPORTUNITY FOR IMPROVEMENT Sarah Hartley 1; Staci Valley 1; Latoya Kuhn 2; Laraine Washer 1; Tejal Gandhi 1; Anurag Malani 3; Carol Chenoweth 1; Sanjay Saint 3; Scott Flanders1. 1University of Michigan, Ann Arbor, Michigan ; 2Ann Arbor VAMC and University of Michigan, Ann Arbor, Michigan ; 3St Joseph Mercy Hospital and University of Michigan, Ann Arbor, Michigan. (Tracking ID # 10810)

BACKGROUND: Urinary tract infection (UTI) is the second most common bacterial infection leading to hospitalization, accounting for 40% of nosocomial infections. Despite the high prevalence of UTI, variability in diagnostic testing and treatment of UTI among hospitalized patients is common and can lead to inappropriate antibiotic use and subsequent antibiotic resistance. We therefore sought to determine the appropriateness of urine culture for UTI and its impact on antimicrobial prescribing.

METHODS: We randomly selected patients admitted to a large academic center between Feb 2008 and Feb 2009 who had urine cultures obtained during the hospital stay. Patients were excluded if they were admitted to intensive care, had a major urinary procedure (e.g., renal transplant, diversion, or stents), were actively being treated for a UTI at the time of admission, started on treatment >48 hours prior to urine collection while admitted, or were an obstetrics patient. Retrospective chart review was independently performed by two physicians to determine the presence of signs or symptoms of a UTI, presence of a urinary catheter, antibiotic administration and urine culture results. Determination of appropriateness for sending urine cultures was compiled from national and professional society guidelines (i.e., from the Centers of Disease Control and Prevention and the Infectious Disease Society of America).

RESULTS: Of the 210 patients included, 97 (46%) patients had an appropriate reason documented to obtain a urine culture. The majority of these (72%) had fever. Urinary symptoms were infrequent, occurring in 22%. In 113 (53.8%) patients no guideline-accepted criterion for obtaining a urine culture was found. Of these 113 patients, 41% had no documented indication for culture while 67 patients (59%) had documented reasons that were not consistent with guidelines, including orthopedic procedures (21%) and altered mental status without a urinary catheter (14%). Of all 210 patients 84% had negative urine cultures. Culture negativity was similar regardless of the presence or absence of indications supported by the guidelines (84% vs. 84%). Of the culture-negative patients, 45% were on antibiotics within 48 hours prior to urine collection. More than 10% of culture-negative patients were started on antibiotics for UTI within 72 hours after culture. The kappa statistic on indications for culture was 0.89, indicating excellent inter-rater agreement.

CONCLUSION: In over one half of hospitalized patients, urine cultures are obtained outside of accepted criteria, often being sent for reasons other than urinary symptoms. In these scenarios, complicating factors included insufficient supporting data (orthopedic procedures) or nonspecific symptoms (altered mental status), which might include UTI in the differential diagnosis. Urine cultures infrequently generated new antibiotic use, perhaps due to high rates of preexisting antimicrobial use. Guidelines relevant to the hospitalized patient are urgently

needed.

VALIDATION STUDY OF HEMOGLOBIN A1C THRESHOLD FOR DIAGNOSING DIABETES: THE ASSOCIATION BETWEEN HEMOGLOBIN A1C LEVELS AND 3-YEAR INCIDENCE OF RETINOPATHY

Yusuke Tsugawa 1; Osamu Takahashi 2; William Taylor 1; Tsuguya Fukui 2; Christina Wee1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts; 2St. Lukes International Hospital, Tokyo, N/A. (Tracking ID # 10814)

BACKGROUND: In 2010, the American Diabetes Association for the first time incorporated hemoglobin A1C (Hgb A1C) level of 6.5% as the diagnostic threshold for diabetes. Experts have historically used the outcomes of retinopathy as the benchmark for defining the diagnosis of diabetes. Due to scarce data on the relationship between Hgb A1C and the incidence of retinopathy, the expert panel relied primarily on several cross-sectional studies examining the association between Hgb A1C levels and the prevalence of retinopathy. In addition, these previous studies were methodologically limited by the lack of adjustment for participants who were pharmacologically treated for diabetes, and by residual confounding from other independent risk factors of retinopathy such as hypertension. To test the validity of the current Hgb A1C thresholds for the diagnosis of diabetes, we conducted the largest longitudinal study to date, and examined the association between Hgb A1C levels and 3-year incidence of retinopathy.

METHODS: We analyzed data from a cohort of 21,137 unselected Japanese adults aged 21 and older who underwent a preventive health check-up between January 1st and December 31st 2006, and returned for follow-up health check-up 3 years later at a medical center in Tokyo, Japan. Fundoscopic digital photos were systematically taken for both eyes for all participants at these check-ups and evaluated by clinical ophthalmologists. Retinopathy was defined as the presence of hard exudates, soft exudates, or retinal hemorrhages. We excluded those with retinopathy at baseline (n=237), with missing information on baseline Hgb A1C (n=24), baseline fundoscopic exams (n=523), or follow-up fundoscopic data (n=371). We conducted a series of logistic regression

models to examine the relationship between baseline Hgb A1C levels and the incidence of retinopathy at 3 years adjusting for baseline demographic factors, those with diabetes receiving treatment, and confounding risk factors for retinopathy.

RESULTS: Of the 19,982 participants in our analytic sample, approximately 49% were male. The mean age (SD) was 50.8 (11.5) years old, the mean body-mass index was 22.5 (3.3) kg/m2, the mean Hgb A1C was5.6 (0.6) %, and the mean fasting blood glucose was 100.3 (14.6) mg/dL;4.5% had diabetes at baseline using Hgb A1C threshold of 6.5%. At 3 years, the cumulative incidence of retinopathy was 0.86% (172/ 19,982). Compared to those with an Hgb A1C level of 5.0-5.4 % (the reference category), adults with Hgb A1C of 6.5-6.9% were associated with a significantly higher risk of developing retinopathy [odds ratio (OR): 3.83, 95% confidence interval (CI): 1.88-7.81, p<0.001] (see Table). This risk remained statistically different after the adjustment for blood pressure, hypertension treatment, low-density lipoprotein, high-density lipoprotein, and diabetes treatment [OR: 2.19, 95% CI: 1.03-4.66, p=0.041]. Those with Hgb A1C between 5.5 and 6.4% did not exhibit higher risk of retinopathy relative to the reference group. CONCLUSION: Our results support current American Diabetes Association guidelines recommending using Hgb A1Clevel of 6.5% or higher as the threshold for the diagnosis of diabetes.

Table. Odd ratios (OR) for developing new retinopathy across different baseline Hgb A1c

` 1: Adjusted for age, sex, systolic and diatolic blood pressure, hypertension treatment, LDL and HDL.

THE BURDEN OF CHRONIC DISEASE AMONG THE BHUTANESE REFUGEE POPULATION AT A US URBAN CLINIC Gayathri Suresh Kumar 1; Michael Saenger 1; Selina Varma 1; Molly Burleson 1; Brandon Kohrt 1; Paul Cantey2. 1Emory University, Atlanta, Georgia; 2Center for Disease Control and Prevention, Atlanta, Georgia. (Tracking ID # 10815)

BACKGROUND: Since the 1980 s, the government of Bhutan, a small impoverished country in Asia, enacted several policies that discriminate against minority ethnic groups living in Bhutan. Facing discrimination and prosecution, an estimated 80,000 people have fled to U.N. refugee camps in Nepal. To date, thousands of refugees have been resettled in countries across the globe including the US. From March 2008 to April 2009, an estimated 1,600 Bhutanese resettled in Atlanta. The Grady Refugee Clinic (GRC) cares for the Bhutanese refugee population in and around metro Atlanta.

In addition to the myriad of struggles facing these patients, many must also cope with the burden of chronic disease. While an increasing prevalence of chronic diseases has been noted among other refugee groups in the United States, it is unclear the magnitude of this burden in this Bhutanese refugee population.

The main objective of this study was to determine the prevalence of certain chronic diseases among the Bhutanese refugee population within this US urban clinic and compare these rates to selected populations.

METHODS: A retrospective cross-sectional study was performed using 66 patient charts of Bhutanese refugees seen in the refuge clinic at GMH. Inclusion in the study required meeting the following eligibility criteria: 1) resettled Bhutanese refugee, 2) 18 years of age or older, and3) seen in the clinic from September 2009 and August 2010. Data were abstracted on selected patient characteristics and certain chronic disease conditions, specifically overweight, obesity, diabetes, and hypertension using a standard data collection form. Diagnoses of these conditions were made using expert national clinical guidelines for each of the conditions (e.g., JNC 7 report for hypertension).

RESULTS: In the clinic population, hypertension was present in 23% (n=15), diabetes in 14% (n=9), overweight in 42% (BMI cut-off of 2529.9 kg/ m2; n=28), and obesity in 9% (BMI cut-off of >30 kg/m2; n=6).

The prevalence of diabetes is significantly higher among the refugee patients seen in our clinic than the Nepali population (13.5% vs 3.9%, respectively; pp=0.099). The prevalence of overweight and/or obesity is higher among the GRC patients than the Nepali population (51.5% vs.8.9%; p=0.229) and the Bhutanese general population (52%; p=0.192). There is no significant difference in prevalence of HTN between the GRC patients (22.7%) and the US (24.2%), Nepali (18.7%), and Bhutanese(22.1%) general populations.

CONCLUSION: This study demonstrates that the Bhutanese refugee population in our urban clinic faces a significant chronic disease burden. It is unclear why such a significant burden exists in this population. Possible explanations include exposures in refugee camps, poor access to care, decreased activity level, stress and depression, acculturation, and adopting unhealthy western behaviors. Exploring the determinants of chronic disease is needed as it

may drive future public health interventions for this vulnerable population.

IMPLEMENTING FACULTY OVERSIGHT OF INTERN WRITTEN SIGN-OUT Jerry Jacob 1; Gregory Bump 2; Saddam Abisse 1; James E Bost 1; Michael Elnicki1. 1University of Pittsburgh, Pittsburgh, Pennsylvania; 2University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania. (Tracking ID # 10820)

BACKGROUND: Recently the Accreditation Council for Graduate Medical Education mandated residency training programs to monitor and teach safe hand-off practices. Resident trainees manage hand-offs with written, verbal or combined methods of sign-out communication. Although poor sign-out contributes to medical errors, there are limited resources available for faculty to assess the content of sign-out, and teach sign-out skills.

METHODS: Based on observed deficiencies in sign-out at our institution we developed a curriculum incorporating the SIGNOUT mnemonic. The curriculum was paired with weekly faculty evaluation and feedback

using a novel structured sign-out evaluation tool. We compared the inclusion of sign-out content, organization and readability in 177 written sign-outs during implementation of the paired curriculum and faculty feedback with 128 written sign-outs prior to implementation. RESULTS: The pairing of a one-page curriculum with weekly faculty evaluation of written sign-out improved the inclusion of advanced directives from 38% to 67% ($p<0.001$) and anticipatory guidance from a mean score of 1.8 [SD 1.2] to 2.3 [SD 1.5] on a 5 point Likert scale ($p<0.001$) by blinded review of sign-out by two independent senior residents. Readability and organization of written sign-out was unchanged. CONCLUSION: A simple curriculum on sign-out content and organization paired with faculty evaluation and feedback can improve some parameters of sign-out. Prompting faculty with a structured evaluation tool of sign-out may be a useful way to improve and teach sign-out skills, as well as satisfy regulatory requirements to monitor and teach safe hand-off practices.

USE OF CLINICAL VIGNETTES TO MEASURE ADHERENCE TO A POINT-BASED VTE RISK ASSESSMENT TOOL: A COMPARISON BETWEEN INTERNAL MEDICINE RESIDENTS AND HOSPITALIST ATTENDINGS.

Michael Sasso 1; Michael Beck2. 1Penn State Hershey Medical Center, Harrisburg, Pennsylvania; 2Penn State Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 10821)

BACKGROUND: Venous thromboembolism (VTE) remains a major cause of morbidity and mortality in hospitalized patients. Evolving guidelines for appropriate VTE prophylaxis have been endorsed by the American College of Chest Physicians (ACCP) for decades; however, appropriate prophylaxis remains underutilized. One possible explanation is that a commonly used point-based VTE risk assessment is too complex to use reliably, and might lead to inaccurate VTE risk stratification and inappropriate prophylaxis. To evaluate this possibility, we constructed clinical vignettes to measure and compare adherence to VTE guidelines between internal medicine residents and attendings.

METHODS: Fifteen clinical vignettes of de-identified cases admitted to a general medical service through our emergency department were reviewed by internal medicine residents and attendings. Prior to completing the vignettes, all physicians received written and oral instructions. Each session lasted 60 minutes and was proctored by the author MJB. After reading each vignette, all physicians was
asked to stratify each vignette as low, medium, or high VTE risk; indentify contraindications to pharmacologic prophylaxis with low molecular weight heparin; and formulate a VTE prophylaxis plan. Responses were evaluated for appropriateness by MJB. The vignettes were scored as appropriate, over-prophylaxis, or under-prophylaxis based on the initial risk assessment and consideration of documented contraindications.

RESULTS: Fifteen vignettes were reviewed by 36 residents and thirteen attendings. As an aggregate, the residents stratified 21%, 37%, and 43% of the vignettes as low, moderate, or high VTE risk, respectively. The attendings stratified 18%, 31%, and 51% as low, moderate, or high VTE risk, respectively. Resident guideline adherence was 65% compared to 78% by attendings. Over-prophylaxis occurred in 28% of resident responses, and in 14% of attendings responses. Under-prophylaxis occurred in 7% of resident responses, and in 8% of attendings responses.

CONCLUSION: Using clinical vignettes, our study demonstrates that, when using a point-based VTE risk assessment tool, attending physicians adhere to the guidelines by prescribing risk appropriate VTE prophylaxis more often than residents. Additionally, residents appear to underestimate VTE risk and over-prophylax more often than attending physicians. Under-prophylaxis was similar between the two groups. This suggests that appropriate VTE prophylaxis may be a teachable skill, and reinforces the ACCP statement that an educational approach should be part of any institutions VTE prevention strategy. This is especially true when an institution is using a point-based VTE risk assessment tool and/or has medical residents performing this task.

TO REFER OR NOT TO REFER OBESITY: ARE PRIMARY CARE PHYSICIANS ADDRESSING THE QUESTION?

Juliette Slomka 1;
Kathleen McTigue 2; Rachel Hess 2; Hemal Shah2. 1University of Michigan/Ann Arbor VA, Ann Arbor, Michigan; 2University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania. (Tracking ID # 10831)

BACKGROUND: The prevalence of obesity, along with patients who are overweight, now encompasses that of over half of the United States adult population. The potential impact obesity has on quality of life, including mortality, is now a prominent focus of current health policy. One goal of the Healthy People 2020 objectives is to increase the proportion of primary care physicians who regularly measure Body Mass Index (BMI). Additionally, obesity has been linked to diverse illnesses including type 2 diabetes mellitus, metabolic syndrome, hypertension, hyperlipidemia and cardiovascular disease (CVD) and carries a large economic burden on our nations health care expenditures. Previous studies demonstrate that patients are actually receiving less guidance from physicians in the primary care setting. METHODS: As part of routine clinical care at the University of Pittsburgh Medical Centers Oakland Practice, patients complete routine screening questions on the Divisions computerized questionnaire, The Functional Assessment Screening Tablet (FAST). Utilizing cross-sectional data, a random sample of 350 patients were selected with self-reported high or low CVD risk factors including those with weight-related comorbidities. We examined the frequency distribution of measured body status according to self-perceived weight status, as well as physician documentation of weight status assessment abstracted from the medical record during a 12-month timeframe. The primary outcomes of interests are whether physicians offered patients with obesity a weight intervention (either a referral to a weight loss program, in-office weight counseling or pharmacotherapy). T tests, chi-square analyses and logistic regression were performed using a significance level of <0.05.

RESULTS: The overall sample was primarily female (62.8%) and the characteristics of the patients in each of the two cardiovascular strata included 72.% female in the low-risk group with a mean BMI of 26.3(SD 5.52) and 53.4% female with a mean BMI of 30.4(SD 7.1) in the high-risk cardiovascular group (p<0.001). In the low and high-risk groups, 16.5% and 40.6% of the patients were obese while32.9% and 37.4% were overweight based on BMI (p<0.001). The majority of patients in the low-risk strata appeared to accurately self-report a healthy perceived weight (53.6%) compared to an overestimation of self-reported healthy weight 35.9% in the high-risk strata (p=0.003). Using SAS software, multivariable logistic regression using backward selection demonstrated that BMI was significant with an adjusted odds ratio of 1.13 (95% CI 1.08-1.2) for physicians offering weight loss interventions.

CONCLUSION: Patients who are not afflicted with comorbid health conditions associated with obesity tend to have a more accurate self-perception of their individual body weight status. BMI predicted whether a physician offers a weight intervention. This information provides insight into how physicians may tailor their assessments, likely due to the time constraints of practicing in an outpatient setting.

PATIENT-CENTERED MEDICAL HOMES AND QUALITY OF PRIMARY CARE FOR CHILDREN: RESULTS FROM A NATIONAL SURVEY Jaya Aysola 1; Asaf Bitton 2; John Z. Ayanian2. 1Harvard Medical School, Boston, Massachusetts ; 2Dept. of Health Care Policy, Harvard Medical School, Boston, Massachusetts. (Tracking ID # 10834)

BACKGROUND: Patient-centered medical homes (PCMH) have gained prominence as models for more coordinated and cost-effective primary care. However, the impact of these models on quality of care merits further evaluation. We examined a large national survey to assess the association of medical homes with several indicators of quality of primary care for children.

METHODS: We analyzed the 2007/2008 National Survey of Childrens Health (NSCH), a nationally representative cross-sectional survey of parents/guardians of children, ages 017 (n=91,642). The primary predictor was access to a patient/family centered medical home (PCMH), measured by a composite score constructed from 19 NSCH survey questions related to the American Academy of Pediatrics definition of PCMH. We analyzed nine measures of quality of care, including number of preventive medical and dental care visits,

receipt of appropriate immunizations and developmental screenings, and the absence of unmet health care needs. In the subset of children with specified chronic conditions, including asthma and mental health disorders, we examined the association of the medical homes with the number of missed school days and receipt of needed mental health services, respectively. In multivariable regression models we assessed the association of medical homes with each quality measure, adjusting for age, gender, race, insurance, poverty, parental education level, primary language, family structure, household employment, geographic region and special health care needs. Analyses were conducted with SUDAAN software to account for the complex survey design.
RESULTS: Access to medical homes was reported for 62% of all children and was more common among children who were Non-Hispanic white, privately insured, in higher income households, and without special health care needs. In adjusted analyses, children with a medical home were more likely than those without a medical home to have one or more preventive medical visits (adjusted OR (aOR) 1.25; 95% CI: 1.11, 1.41) and to receive developmental screenings (aOR 1.25; 95% CI: 1.04, 1.51), and much less likely to have any unmet medical needs (aOR 0.27; 95% CI: 0.23, 0.32). Parents/guardians of children with medical homes as compared to those without reported that they were more likely to have medical providers ask about their childs development (aOR 1.54; 95% CI:1.34, 1.78). In contrast, among children with behavioral or developmental disorders, those with medical homes were less likely to receive needed mental health services than those without (aOR 0.65; 95% CI: 0.49, 0.85). Among children with asthma (n=7518), the mean adjusted number of missed school days due to illness were days lower among those with a medical home than those without a medical home (5.00.3 vs. 6.70.5, $p<0.001$).
CONCLUSION: Patient-centered medical homes were associated with improved quality of care on some but not all pediatric measures. Our results underscore the benefits of the medical home model in primary care while highlighting areas for improvement. As plans for broad implementation of the patient-centered medical home proceed, evaluations of medical homes should assess the need for improved care coordination for mental health services.

BRIEF VERSUS EXTENDED COUNSELING FOR HIV CLINIC BASED BUPRENORPHINE TREATMENT OF OPIOID DEPENDENCE Jeanette Tetrault 1; Brent Moore 1; Declan Barry 1; Patrick OConnor 1; Richard Schottenfeld 1; David Fiellin 1; Lynn Sullivan1. 1Yale University School of Medicine, New Haven, Connecticut. (Tracking ID # 10835)

BACKGROUND: Untreated opioid dependence adversely affects HIV outcomes. Integrating buprenorphineinto HIV treatment settings is feasible. However, the optimal level of counseling to augment pharmacotherapy for opioid dependent, HIV-infected patients has not been established. METHODS: We conducted a 12-week randomized clinical trial of physician management (PM) versus PM plus enhanced medical management (EMM). All subjects received buprenorphine treatment. PM was a brief, manual guided counseling strategy and EMM was an expanded nurse administered drug counseling strategy that included antiretroviral (ARV) and buprenorphine adherence. The primary outcomes were percentage of opioid negative urine toxicologies, maximum duration of continuous abstinence from illicit opioids, buprenorphine treatment retention, CD4 count and percentage of subjects with non-detectable HIV viral load. Study group differences on treatment retention were evaluated using the Mantel Cox log rank test; differences on other outcome variables were examined using chi-square tests for categorical data and t-tests for continuous data. General estimating equations (GEE) were used for categorical repeated measure outcomes, and mixed-model ANOVAs for continuous repeated measures.
RESULTS: 47 subjects were enrolled and randomized. There were no differences in baseline characteristics between the two groups with the exception of duration of HIV disease (15.4 years in the PM group vs.8.7 years in the PM + EMM group, p=0.001). At 12 weeks, there were no differences between the two groups in percentage of opioid negative urines (61.6% PM vs. 69.0% PM + EMM, p=0.5) or maximum duration of continuous abstinence (4.9 weeks PM vs. 5.2 weeks PM + EMM, p=0.8). There was a trend toward increased

retention in the PM group compared with the PM + EMM group (80% vs. 59%, p=0.1). CD4 counts increased from 312 at baseline to 338 cells/mm3 at 12 weeks in the PM group and from 295 to 308 cells/mm3 in the PM + EMM group (p=0.9). The percentage of subjects with non-detectable HIV viral loads decreased from 69% at baseline to 35% at 12 weeks in the PM group and from 65% to 52% in the PM + EMM group (p=.01).
CONCLUSION: Patients receiving buprenorphine along with PM and PM + EMM in a HIV clinical setting demonstrated a high degree of opioid abstinence, treatment retention, and a decrease in HIV viral load.

However, we were unable to detect a difference in efficacy between PM and PM + EMM, though there was a trend toward increased retention and greater decrease in viral load with PM only. Strategies to optimize counseling approaches and impact both opioid dependence and HIV outcomes for this specialized population are needed.

PAYMENT SOURCE AS AN ADJUSTMENT FOR HOSPITAL READ-MISSION RATES John S. Hughes 1; Richard Fuller 2; Elizabeth McCullough 2; James Vertrees2. 1Yale School of Medicine, New Haven, Connecticut; 23M Health Information Systems, Silver Spring, Maryland. (Tracking ID # 10844)

BACKGROUND: Preventable readmissions are among the measures increasingly used to evaluate the quality of hospital care. Current risk-adjustment methods may not be sufficient to account for the susceptibility of low-income individuals to more frequent hospitalizations, which can result in disproportionately higher than expected readmission rates for safety-net hospitals. We therefore examined the residual effect of payment source, a surrogate for socio-economic status and age, on predicted readmission rates after adjustment for case-mix and severity of illness.

METHODS: We used administrative data from January 2005 through April 2007 from 165 Florida hospitals with at least 2,000 eligible admissions, comprising 4,626,909 hospitalizations. Each admission was linked at the patient level so that readmissions to any hospital could be identified. We identified 30-day preventable readmissions to any hospital using Potentially Preventable Readmissions (PPR), a method that determines preventability of repeat hospitalizations based on whether there is a plausible causative relationship between the reason for the initial admission (IA) and the readmission (RA). We used All Patient Refined Diagnosis Related Groups (APR DRGs) to categorize reasons for hospitalization, and to adjust for severity of illness (SOI). Each eligible admission was assigned to a base APR DRG and to one of 4 SOI levels within the APR DRG. We calculated an expected readmission rate for each hospital using indirect standardization of statewide average rates within each APR DRG and severity level. We then examined overall expected and actual PPR rates within categories of patient age, the presence of a major mental health or substance abuse diagnosis, and categories of payer source. We used regression analysis to examine the influence of each of these factors on the accuracy of the PPR rate, and to generate modifications to the APR DRG risk adjustment.

RESULTS: Actual PPR rates for individual hospitals ranged from2.27% to 20.79%, and ranged from 2.42% below to 8.18% above the expected rates derived from statewide averages. In the examination of payer source, the PPR model underestimated the statewide rate for Medicare patients (10.3% predicted versus 11.2% actual) and Medicaid patients (7.7% predicted versus 9.0 actual), while it overestimated the PPR rate for commercial insurance (6.7% predictedv. 5.1% actual). We used coefficients derived from regression analysis to create adjustment factors for payment source and applied them to the standard APR DRG model, yielding predicted overall PPR rates much closer to the actual values for Medicare (11.16% v. 11.24% actual), Medicaid (8.88% v. 8.98% actual), and Commercial insurance(5.08% v. 5.10%).

CONCLUSION: There appear to be additional risks for preventable readmissions associated with payment source that are not measured in the PPR risk adjustment mechanism using APR DRGs. This study shows that adjustments for payment source, and likely for other socio-demographic variables (education, income), when available, can be readily incorporated into a risk-adjustment model. Not adjusting
for payment source, and implicitly for the effects of poverty (Medicaid) and age (Medicare) could unfairly

penalize hospitals that care for disproportionate shares of Medicare and Medicaid patients, while simultaneously favoring hospitals with larger numbers of privately insured patients.

TRANSLATING MEDICAL STUDENT KNOWLEDGE OF QUALITY IMPROVEMENT: A QUALITY IMPROVEMENT PILOT CURRICULUM DEMONSTRATION Jason Fish 1; Carl Stevens 1; LuAnn Wilkerson1. 1UCLA, Los Angeles, California. (Tracking ID # 10846)

BACKGROUND: With a persistent gap between evidence-based best practices and actual medical care in the US, healthcare systems are investing deeply in the integration of quality improvement (QI) methods but are lacking a physician workforce committed to and trained in project-based QI methodology. To address this, we developed and piloted a QI curriculum, embedding QI didactic and practical elements in the core third year internal medicine clerkship.

METHODS: The curriculum includes didactics on basic principles of QI methodology and health services research. In 20092010, 23 students were exposed, and assessment of all third year medical students ability to develop any structured QI strategy was determined using the Objective Structured Clinical Examination. The grading of the exam focused on broad QI categories.

RESULTS: The mean score on the exam was 43%. Those students exposed to the curriculum scored 20.9% higher than those students not exposed (p less than 0.001). We also found that those students participating in the QI pilot curriculum scored 21.1% higher than those students not participating in the curriculum (P less than 0.001), controlling for all students reporting exposure to some other QI didactics or QI projects (neither of which were significant in the multivariate model). Using t-tests, we identified that students in the pilot curriculum were more likely to recognize the importance of identifying key stakeholders, current institutional processes, and the need for continuous evaluation.

CONCLUSION: Out data indicates that our pilot demonstration of a QI curriculum using QI and health services methodology, coupled with practical business modeling tools, improved our students ability to recognize opportunities for QI and develop key strategies for improving quality. Yet, our data also indicates that students still have difficulty applying QI to clinical practice. More research is needed to identify how best to teach QI to medical students in a way that translates into appropriate application.

HOW DO RESIDENTS LEARN TO PERFORM HIGH-QUALITY DISCHARGE CARE? A STUDY OF PROFESSIONALIZATION AND CORE COMPETENCY DEVELOPMENT S. Ryan Greysen 1; Danise Schiliro 2; Leora Horwitz 3; Leslie Curry 4; Martha Radford 2; Elizabeth Bradley4.

1Yale University, RWJ Clinical Scholars Program, New Haven, Connecticut ;

2New York University Medical Center, New York, New York ; 3Yale University School of Medicine, New Haven, Connecticut ; 4Yale University School of Public Health, New Haven, Connecticut . (Tracking ID # 10850)

BACKGROUND: The Accrediting Council for Graduate Medical Education requires residents to develop competency in Systems Based Practice (SBP) and Practice-Based Learning Improvement (PBLI), however, we have limited understanding about how and when residents develop these competencies as they progress through training. Discharge care, an intrinsically systems-based practice, is

an ideal setting to explore opportunities and challenges for competency development in SBP and PBLI during post-graduate medical education.

METHODS: We employed a qualitative approach using in-depth, in-person interviews to describe the discharge process from the perspective of residents and to generate hypotheses about how residents learn to perform high-quality discharge care. We developed a purposeful sample of participants with attention to post-graduate year, gender, and experience in two internal medicine training programs, Yale and New York University (NYU), to ensure a wide breadth of experiences. We have completed 17 interviews with Yale residents and have begun

enrollment of residents at NYU. Interviews were professionally transcribed and independently coded by two investigators using the constant comparative method and discrepancies were resolved by consensus. Additionally, three senior team members with diverse backgrounds and experiences provided layered input for coded transcripts. Thematic analysis was performed by the entire research team.
RESULTS: We analyzed transcripts from 17 residents: Ten (59%) were seniors (PGY-2 or PGY-3), seven (41%) were interns (PGY-1), and ten (59%) were female. Interns and seniors differed in their understanding of four aspects of discharge care: teamwork, uncertainty, safety, and continuity. Regarding teamwork, interns focused on collaborating with other physicians, while seniors recognized the interdisciplinary nature of discharge planning and engaged nurses, social workers, and case managers as part of the discharge team. While all participants described challenges with the inherent uncertainty of discharge timing, seniors differed from interns in their use of advanced planning strategies to anticipate challenges, often starting discharge planning at the time of admission. Concerning patient safety, interns tended to focus on avoiding medication errors whereas seniors took a more comprehensive view of a safe discharge to include patients home environment and social support system. Similarly, once patients were discharged, interns described difficulty with continuity and learning post-discharge outcomes whereas seniors typically developed methods to follow up with patients after discharge. When asked explicitly how they learned to perform high-quality discharge care, both interns and residents indicated there was no formal training or structure for learning about the discharge process, only peer-to-peer instruction and learning by doing on the wards.
CONCLUSION: Discharge care may be an overlooked opportunity in post-graduate medical education to teach concepts of SBP and PBLI competencies explicitly. Although our findings suggest residents are acquiring aspects of these competencies, learning about discharge care is unstructured and individual experiences may vary considerably. Educational interventions to standardize learning about discharge care and further emphasize teamwork, patient safety, and post-discharge outcomes of care may improve the development of SBP and PBLI during residency training. Such interventions may also help shape discharge practices at teaching hospitals to improve the overall quality of discharge care.
RETROSPECTIVE ANALYSIS OF HPV VACCINATION STATUS IN FEMALE PATIENTS: DOES THE VACCINATION PROCESS MATTER? Alina Katsman 1; Jason Fish2. 1University of California, Los Angeles, Los Angeles, California; 2UCLA, Los Angeles, California. (Tracking ID # 10854)
BACKGROUND: Clinical trials have shown that vaccines against HPV types 16 and 18, such as Gardasil, are almost 100% effective in preventing high-grade pre-cancer. According to a November 2010 report from the Centers for Disease Control and Prevention (CDC), only 17 percent of adult women aged 19 to 26 have received at least one shot of the HPV vaccine. It is unclear why the national rate is so low; we hypothesize that the current rate of vaccination for all eligible women attending two busy primary care practices at an academic healthcare center will be similar to the national rates and that by understanding the current vaccination process employed in the clinics may explain the low rates.
METHODS: We performed a retrospective analysis of all eligible female patients aged 18 to 26 from June 1, 2009 to May 31, 2010 at both primary care practices. We first used billing data to identify all eligible patients that came into the clinics during the inclusive time period. The inclusion criteria included female patients age 18 to 26 during the time period June 1, 2009 to May 31, 2010 and the exclusion criterion was female patients who never saw a medical doctor. For all patients identified, we performed a chart audit to determine whether these eligible patients received the HPV vaccine, had documentation that the vaccine was discussed, or had documentation that the patient declined that vaccine. Using quality improvement techniques, we also identified process flow diagrams to understand better the vaccination processes employed in both clinics.
RESULTS: From the original billing data, there were 1251 eligible females aged 1826 who were seen at both primary care practices over the course of one year (6/1/09-5/31/10). Excluding 2 patients who did not see a medical doctor, the final cohort for our analyses consisted of 1249 patients. We found that each patient visited a

physician an average of 1.8 times during this time period, and that 65% of the patients had an identified primary care physician at the center. After reviewing both billing data and chart audits, we found that 38.8% of eligible females had documentation of receiving the Gardasil vaccine at some point; 2.4% had declined the vaccine; and 8% were still undecided but had the discussion with their physician. Overall, 50.8% of the cohort was found to have an unknown status of the HPV vaccine. We looked at whether having a primary care physician affected these rates. Of those that had a PMD, 57.4% have a known vaccination status (either got the vaccine, declined, or discussed) while 42.5% of patients had an unknown status. Of those that did not have a PMD assigned, 33.7% have a known vaccination status and 66% did not. Using quality improvement techniques, we identified process flow diagrams indicating a lack of infrastructure for ordering and tracking the HPV vaccinations.
CONCLUSION: Since 2006, the HPV vaccine, specifically Gardasil, has been approved for the prevention of cervical, vulvar, and vaginal cancer associated with HPV types 16 and 18 and for the prevention of genital warts caused by HPV types 6 and 11 in female patients ages 9 through 26. Although our data indicate that these two primary care practices in an academic healthcare center are vaccinating more patients against HPV than the national average, the HPV vaccination status of 50% of the patients that come into the clinics remains unknown. In addition, for those patients engaging the healthcare system with no identified PMD, the rates are even lower which also could be seen as missed opportunities for preventive care. In examining the processes of administering the vaccine, the lack of infrastructure may be accounting for the significant variability found, given that the current process of vaccination rests solely on the physician to ask about vaccination status, order the vaccine and document accordingly. While the overall percentage of vaccination is higher than that of the national data, we feel that an infrastructure with reminders and proper tracking could improve upon the centers current rate. Further research should be done to identify strategies for improving the vaccination rates in the context of the complex structures of the academic healthcare center.

A WEB-BASED EBM EDUCATIONAL PRESCRIPTION TO EVALUATE RESIDENT EBM COMPETENCY

David Feldstein 1; Matthew Maenner 1; Elizabeth Allen 2; Lisa M Baumann Kreuziger 3; Scott Kaatz 4; Laura J Nicholson 5; M. E. Beth Smith 3; Mark Albanese1. 1University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin ;
2Oregon Health Sciences University, Portland, Oregon ; 3University of Minnesota Medical School, Minneapolis, Minnesota ; 4Henry Ford Hospital, Detroit, Michigan ; 5Scripps Clinic Medical Group, San Diego, California .
(Tracking ID # 10858)

BACKGROUND: The expanding volume of medical research makes it critical for physicians to learn how to incorporate evidence into clinical care. The ACGME requires that residents are competent at practicing evidence-based medicine (EBM) as part of the practice based learning and improvement competency. Currently there are no validated tools to measure resident EBM competency. The objective of this study is to evaluate the feasibility and reliability of a novel EBM educational prescription (EP) in evaluating internal medicine residents EBM competency. The study also evaluated the effect of EP use on patient care decisions.
METHODS: The study was performed over a 6 month period at five internal medicine residency programs throughout the US. Residents completed EPs in various clinical settings including continuity clinic, inpatient ward rotations and outpatient block rotations. The web-based EP was developed to guide residents through the steps of EBM to answer patient care questions. Residents used the EP to describe a clinical question, document a search strategy, analyze the quality of evidence found, report the results of the evidence and describe how to apply the evidence to their individual patients. EP results were presented to attending physicians who graded the EP using a web-based form. EPs were graded on: 1) question formation; 2) searching;3) evaluation of evidence; 4) application to patient; 5) ability to teach the team; 6) overall competence. Each area was scored on a scale of 1 (not yet competent) to 9 (superior) using an integrated grading rubric to provide anchors. The website includes attending training in EP grading. Time to complete and

grade EPs, satisfaction with the EP and whether the EP changed patient care were recorded with each EP. Residents and attendings completed end of study questionnaires about their attitudes toward the EP and barriers to its use. Data collection will be completed in March 2011.
RESULTS: Preliminary results showed that 216 residents completed 499 EPs and 100 attendings graded 344 of those EPs. The average overall competency score was 6.51 (SD 1.46) out of 9. Residents took a median of 50 minutes (Interquartile Range (IQR) 3065) to complete EPs and attendings took a median of 15 minutes (IQR 1020) to grade each EP. Residents reported that 21% of the completed EPs changed the patient care plan, 6% would have changed the patient care plan if they had the information sooner and 52% confirmed the current care plan. To date, 86 residents and 25 attendings completed end of study questionnaires. Residents felt that performing EPs was probably or definitely a valuable experience (72.6%) and changed how they approached patient care (63.1%). The main barriers to resident use of EPs were time (52.4%) and comfort using evidence resources (17.9%). Attendings felt that the EP probably or definitely was a valuable tool in evaluating residents EBM skills (91.3%) and that it probably or definitely improved patient care (78.2%). Most attendings said that they would continue using EPs upon completion of the study (78.2%). CONCLUSION: It is feasible to incorporate an online EP into clinical care in diverse clinical settings. EPs impact patient care plans. Overall, the EP process was well received by residents and faculty and felt to be a valuable tool. This study represents early evidence of the first valid tool to evaluate resident EBM competency during clinical care. Future analysis of the data will evaluate inter-rater reliability of the EP grading as well as factors affecting grading. A current study is underway to compare EP grades with grades on an EBM objective structured clinical exam (OSCE).
EFFECT OF MEDICARE PART D BENZODIAZEPINE EXCLUSION ON PSYCHOTROPIC USE AMONG BENZODIAZEPINE USERS Michael K. Ong 1; Haiyong Xu 1; Lily Zhang 1; Francisca Azocar 2; Susan L. Ettner1.
1UCLA, Los Angeles, California; 2OptumHealth Behavioral Solutions, San Francisco, California. (Tracking ID # 10860)
BACKGROUND: The Medicare Modernization Act (MMA) created prescription drug coverage through Medicare Part D starting in 2006, but specifically excluded benzodiazepines from coverage due to studies showing adverse effects among elderly patients. However, when used appropriately, benzodiazepines are an effective, low-cost treatment for anxiety. We evaluated the effect of the benzodiazepine coverage exclusion on psychotropic prescribing patterns and costs among benzodiazepine users with prescription drug coverage before and after MMA implementation.
METHODS: We compared two cohorts of patients drawn from the same insurer who were prescribed benzodiazepines through the end of 2005. The intervention cohort was drawn from elderly individuals (N=19,339) enrolled in a large Medicare Advantage (MA) plan and the comparison cohort was drawn from near-elderly individuals (N=3,488) enrolled in a managed care plan. Both cohorts had prescription drug coverage before and after MMA implementation but benzodiazepine coverage was excluded for the intervention cohort after MMA implementation. Predicted psychotropic drug use rates and expenditures were generated from multivariable regression analyses that adjusted for time period (2006 and 2007 vs. 2005), age, gender, and comorbidities. Significance was determined as $p<.05$.
RESULTS: Benzodiazepine claim occurrences (including noncovered prescription fills) dropped from 100% in 2005 to 54.2% in 2006 and74.8% in 2007 among the intervention cohort; among the comparison cohort, this dropped from 100% in 2005 to 81.9% in 2006 and57.5% in 2007. Correspondingly, benzodiazepine costs dropped from $149 in 2005 to $73 in 2006 and $67 in 2007. From 2005 to 2007, predicted non-benzodiazepine psychotropic drug claim occurrences significantly increased among the intervention cohort (35.8% to39.2%) but significantly declined among the comparison cohort(58.4%to 47.4%). Similarly, predicted non-benzodiazepine psychotropic drug expenditures significantly increased among the intervention cohort ($163 to $207) but

significantly declined among the comparison cohort ($647 to $571) from 2005 to 2007. These changes were primarily due to significant differences in use of antidepressants (intervention cohort, 34.0% to 37.7%, $105 to $114; comparison cohort, 47.1% to 39.2%, $399 to $322) and anxiolytics (intervention cohort, 8.0% to 12.3%, $24 to $45; comparison cohort, 18.4% to14.6%, $115 to $89).
CONCLUSION: Elderly benzodiazepine users continued to use benzodiazepines after its coverage exclusion, although at lower rates than before. Correspondingly, they increased use of non-benzodiazepine psychotropic drugs, particularly antidepressants and anxiolytics, although the magnitude of this increase does not appear to compensate for the reduction in benzodiazepine use. Use of benzodiazepines continued among the elderly despite negative financial incentives, possibly due to the low costs of such medication. While some substitution occurred with antidepressants and anxiolytics, the gap in psychotropic drug use may reflect either possible increases in psychotherapy or reduced use of treatment.

EFFECT OF MEDICARE PART D BENZODIAZEPINE EXCLUSION ON PSYCHOTROPIC USE AMONG PATIENTS WITH NEW ANXIETY DISORDERS Michael K. Ong 1; Lily Zhang 1; Haiyong Xu 1; Francisca Azocar 2; Susan L. Ettner1. 1UCLA, Los Angeles, California;
2OptumHealth Behavioral Solutions, San Francisco, California. (Tracking ID # 10861)
BACKGROUND: The Medicare Modernization Act (MMA) created prescription drug coverage through Medicare Part D starting in 2006, but specifically excluded benzodiazepines from coverage due to studies showing adverse effects among elderly patients. However, when used appropriately, benzodiazepines are an effective, low-cost treatment for anxiety. We evaluated the effect of the benzodiazepine coverage exclusion on prescribing patterns and costs, and outpatient behavioral care, among Medicare patients with new anxiety diagnoses.
METHODS: We compared two cohorts of patients drawn from the same insurer, an intervention cohort (N=8,397) of elderly individuals from a large, national Medicare Advantage (MA) plan, and from a comparison cohort (N=1,657) of near-elderly individuals enrolled in a managed care plan. Both cohorts had prescription drug coverage before and after MMA implementation, but benzodiazepine coverage was excluded for the intervention cohort after MMA implementation. Each cohort was comprised of individuals with new anxiety diagnoses in the first six months of 2005, 2006, and 2007. New diagnoses were defined as having no encounters with anxiety diagnoses in the prior six months. Predicted use and expenditure outcomes were generated from multivariable regression analyses that adjusted for time period (2006 and 2007 vs. 2005), age, gender, and comorbidities. Significance was determined as $p<0.05$.
RESULTS: Among the intervention cohort, those diagnosed in 2005 were predicted to have significantly higher rates of covered psychotropic drug claims than those diagnosed in 2006 or 2007(75.4% vs. 45.9% and 50.0%); this difference was largely due to significantly reduced covered benzodiazepine claims, with 63% among those diagnosed in 2005 vs. 0.9% and 1.3% among those diagnosed in 2006 and 2007). Non-benzodiazepine (mostly antidepressant and anxiolytic) predicted claim occurrences among the intervention cohort significantly increased from 40.3% in 2005, to45.5% and 49.5% in 2006 and 2007. Predicted overall annual drug expenditures among the intervention cohort non-significantly increased from $125 in 2005 to $129 in 2006, and significantly increased to $154 in 2007. In contrast, among the comparison cohort, predicted claim occurrences did not significantly differ from 20052007 for all psychotropic drugs (74.6%, 74.4%, 77.7%), benzodiazepines (48.2%, 43.5%, 48.0%) and non-benzodiazepine psychotropic drugs (59.2%, 59.7%, 57.9%). Predicted overall psychotropic drug expenditures for the comparison cohort were relatively constant from 20052007 ($438, $464, $381) although there was a significant decline in predicted benzodiazepine expenditures in 2006 ($39) and 2007 ($38) compared to 2005 ($67). There were no significant differences in outpatient behavioral care across

all years in either cohort.
CONCLUSION: Among elderly patients with new anxiety diagnoses, the benzodiazepine exclusion implemented in MMA resulted in increased use of non-benzodiazepine psychotropic drugs but overall less covered psychotropic drug use. Despite this reduction in overall psychotropic drug use and spending on benzodiazepines, overall psychotropic drug expenditures increased for the intervention group. The gap between psychotropic use before and after MMA may reflect reduced use of treatment, but not increased psychotherapy. Increasing psychotropic drug expenditures suggest that
potential reductions in inappropriate benzodiazepine use were offset with slightly higher drug expenditures.
EFFICACY OF PATIENT REMINDERS LETTER TO IMPROVE A D H E R E N C E T O P R E V E N TAT I V E A N D D I A G N O S T I C RECOMMENDATIONS Zhou Zhang 1; Jason Fish2. 1UCLA, Woodland Hills, California; 2UCLA, Los Angeles, California. (Tracking ID # 10864)
BACKGROUND: Recent literature identifies that completion of recommended services is marginal. Given these low rates, physicians have been trying many strategies to increase adherence; specifically, strategies have involved letters, phone calls, and text messages. While each has been shown to be effective for preventative services, it is unclear how each reminder strategy may affect completion of diagnostic study recommendations. Further, it is also unclear how best to implement these strategies in complex healthcare organizations. We hypothesize that while these strategies may benefit patients and increase adherence to both preventative and diagnostic study recommendations, there will simultaneously be a need to identify and improve organizational processes to facilitate patient participation in completing these recommended services.
METHODS: Using pilot data from a database of all ordered recommended care for both preventative and diagnostic study recommendations from one general internists outpatient practice at an academic health center from 20082009, we collected completion rates of these recommendations. The database included record of completion of recommended care as well as documentation of two patient reminder letters being sent for each order. The physician followed a standard protocol for sending two reminder letters. Employing quality improvement techniques, we also generated process flow diagrams for preventative services and diagnostic study recommendations (which included laboratory, specialist referrals, and radiological studies) to identify how patients engage the medical system to complete the recommended services.
RESULTS: During the 12 month study period, a total of 1630 recommended services were recorded (251 preventative services, 416 specialist referrals, 683 labs, and 180 radiology and other diagnostic studies). Preventative services had a completion rate of 45% without any reminder letters, similar to published studies. With one reminder letter, this completion rate increased 13% and, with a second reminder letter, the completion rate increased an additional 8%. For the diagnostic study recommendations, baseline completion rates were found to be: 65% for referrals, 82% for labs, and 79% for radiological studies. The three diagnostic study recommendations increased 7-12% after a first reminder letter, with the second reminder letter increasing the completion rate by 1-3%. Using QI techniques, we generated process flow diagrams which identified complicated process for preventative services in comparison to diagnostic study recommendations.
CONCLUSION: Completion of recommended preventative services was significantly improved with two patient reminder letters. However, for some preventative services, such as colonoscopy for colon cancer screening, we did find that the completion rate remained low despite the two reminder letter intervention. We also found that for diagnostic study recommendations, one reminder letter offered an additional benefit; whereas, the second reminder letter offered minimal benefit. Our process flow diagrams also indicated that some of the processes for services, such as preventative services, have complicated processes, which may account for the differences of the effect the reminder-letter intervention had on some of the recommended services. Further research is needed to identify improved strategies for increasing

completion rates, with an understanding of these strategies in the context of organization processes.

UPPER GASTROINTESTINAL SYMPTOMS DETERMINED USING A FREQUENCY SCALE FOR THE SYMPTOMS OF GASTROESOPHAGEAL REFLUX DISEASE ARE AFFECTED BY VERTEBRAL DEFORMITIES IN ELDERLY JAPANESE INDIVIDUALS Yoshinori Tokushima 1; Hitoshi Eguchi 1; Yuta Sakanishi 1; Yuichiro Eguchi 1; Satoshi Matsunaga 1; Tsuneaki Yoshioka 2; Shu Soejima 1; Yasutomo Oda 1; Sei Emura 1; Ryuichi Iwakiri 3; Kazuma Fujimoto 10; Takashi Sugioka 1; Shunzo Koizumi1. 1Saga Medical School, Saga, N/A; 2Saga Medhical school, Saga, N/A; 3Saga Medical School Internal Medicine, Saga, N/A. (Tracking ID # 10865)

BACKGROUND: According to the World Health Statistics 2010 reported by the World Health Organization, Japanese people have the longest average lifespan in the world. The quality of life for elderly individuals is thus a priority issue in an aging society. Gastroesophageal reflux disease (GERD) is a lifestyle-related disease that shows a markedly increased prevalence in elderly individuals in Japan. Increased abdominal pressure, caused by kyphoscoliosis, is thought to be one factor responsible for this increased incidence. In a previous study, we found that the pathogenesis of GERD diagnosed by upper gastrointestinal endoscopy in elderly patients was affected by the increase in intra-abdominal pressure caused by vertebral deformities, including spondylosis deformans. However, the relationship between vertebral deformities and GERD, including GER symptoms, in elderly individuals remains unclear. The aim of this study was, therefore, to clarify the relationship between vertebral deformities and GER symptoms evaluated by questionnaire in the elderly general population in Japan.
METHODS: Elderly individuals who visited four adult day care services in Japan were enrolled in this study. GERD symptom scores were assessed using a frequency scale for the symptoms of GERD (FSSG) questionnaire. The degree of spine shortening was determined by the difference between arm span (cm) and body height (cm) (DAH), and medication history associated with GER symptoms was obtained. RESULTS: A total of 112 elderly individuals were evaluated (89 female; mean age 80.16.1 years). The mean body mass index was 21.03.9 and the mean DAH was 6.46.4 cm. Sixteen individuals (14%) had significant GER symptoms (FSSG score >8), 61 (54.5%) had mild GER symptoms (FSSG score 17), while 35 (31%) had no symptoms evaluated by FSSG. Of the patients with GER symptoms evaluated by FSSG, only five (4.5%) were treated with proton-pump inhibitors, and 12(10.7%) were treated with H2 blockers. FSSG score and symptoms due to functional dyspepsia were both significantly correlated with DAH (r=0.333 and r=0.337, respectively, both pCONCLUSION: This study confirmed a positive relationship between GER symptoms and vertebral deformities. An FSSG questionnaire can provide a useful and inexpensive method for identifying GERD patients in the elderly general population.

TOWARD UNIVERSAL HIV TESTING: IS THE CDC RECOMMENDATION OF OPT-OUT SCREENING THE ANSWER? Anish P Mahajan 1;
Jennifer N Sayles 2; Janni Kinsler 3; Saloniki James 2; Jacqueline Rurangirwa 2; Rishi Manchanda 4; Lakshmi Makam 5; Martin Shapiro1.
1David Geffen School of Medicine at UCLA, Los Angeles, California ; 2Los Angeles County Office of AIDS Programs &Policies, Los Angeles, California ; 3UCLA School of Public Health, Los Angeles, California ; 4St. Johns Well Child &Family Center, Los Angeles, California ; 5Hubert Humphrey Comprehensive Health Center, Los Angeles, California . (Tracking ID # 10866)

BACKGROUND: Most Americans have not been tested for HIV, and 20% of those infected are unaware. To expand testing, the CDC recommends routine opt-out HIV screening, in which patients are told they will undergo testing unless they decline. Objective: To determine if opt-out screening is associated with greater testing offers and patient acceptance of screening than routine opt-in or risk-based testing.
METHODS: At 2 safety-net clinics, participatory research methods were used to create 3 screening interventions: physician-initiated (P-I) optout, nurse-initiated (N-I) opt-out, and N-I opt-in. Using a quasi-experimental time samples design, each intervention was implemented for a 2-month interval over 6 months. 14,872 patients were eligible for screening. Differences in testing offers and patient acceptance of screening

between the interventions and risk-based testing (standard of care) were assessed. Multivariate regression was used to identify correlates of screening refusal.
RESULTS: Relative to risk-based testing, the interventions increased the offer rate (11% vs. 25% p<0.05) and actual testing rate (7% vs. 14% p<0.05). Although offer rates were similar between opt-out and opt-in, the physician offer rate was greater than nurses (28% vs. 22% p<0.05). Overall percentage of patients accepting screening in optout and opt-in interventions were similar (59% vs. 56% p=0.09), but P-I opt-out was associated with greater acceptance than N-I opt-out (65% vs. 54% p<0.05). Recent test, older age, female sex, and African-American ethnicity were associated with refusing screening (p<0.05).
CONCLUSION: Routine HIV screening in ambulatory care is feasible, and resulted in at least a 2-fold increase in the percentage of clinic patients offered screening and proportion undergoing testing. The CDC recommendation for opt-out screening was not associated with greater patient acceptance of screening compared to opt-in screening. Such strategies do not assure universal offering of HIV testing.
A MULTISITE STUDY COMPARING MEDICAL STUDENT AND FACULTY OPINIONS REGARDING ONLINE PROFESSIONALISM Lynn Malec 1; Erik Black 2; Beatrice Boateng 3; Reed Van Deusen4.
1Childrens Hospital of Pittsburgh, Pittsburgh, Pennsylvania ;
2University of Florida College of Medicine, Gainesville, Florida ;
3University of Arkansas for Medical Sciences, Little Rock, Arkansas ;
4Univeristy of Pittsburgh Medical Center, Pittsburgh, Pennsylvania. (Tracking ID # 10873)
BACKGROUND: Educating physicians-in-training about issues related to medical professionalism remains an important yet elusive challenge for medical educators. The Accreditation Council for Graduate Medical Education (ACGME) counts professionalism as a core competency in resident education however little guidance exists as to how to teach or evaluate trainees regarding professionalism. Professionalism education must encompass domains such as compassion, responsiveness to patient needs, respect for patient privacy, and sensitivity to diverse patient populations. Research has already established that unprofessional behavior in medical school is associated with later State board disciplinary action. Recent advances in Internet technologies and the consequent rise in popularity of online social media sites have added to the complexity associated with educating physicians-in-training about professionalism. Facebook, as a dominant online social media destination, has garnered specific attention from medical education researchers. Since the emergence of social media sites, medical trainees activities outside the workplace are increasingly publically available.

With this change, come new questions as to what constitutes professional behavior.
METHODS: A survey composed of vignettes, questions related to demographics, and opinion questions was electronically distributed to first year medical students and faculty in internal medicine and pediatrics at three academic medical institutions (University of Pittsburgh, University of Florida, and University of Arkansas). The vignettes contained de-identified photographs, quotes, and case scenarios. All vignettes were originally posted by medical trainees and were publicly available at the time they were obtained from the source websites. Participants were asked their opinions on how acceptable each vignette was to be posted online for four different levels of learner (premedical student, medical student, resident, and faculty member). There were three possible levels of acceptability for each level of learner: acceptable if posted on a public site, acceptable if posted on a protected site, and not acceptable. Comparisons between medical student and faculty responses were done using the Chi-squared statistic. This study was approved by the IRB at all three institutions.
RESULTS: The survey response rate was 30%. On average, medical students were 24 years old (SD=3.2) and faculty were 45 (SD=10.6). Vignette #1 was a picture of a woman standing in a parking lot holding a keg. If a premedical student posted this picture, 21.5% of faculty and 14.3% of medical students felt it would be

unacceptable (P<.05). No statistically significant difference was found between medical students and faculty for this image if it were posted by medical students, residents, or faculty members. Vignette #2 was a picture of a man and woman on a beach and he is kissing her chest. If a premedical student posted this, 75.9% of faculty and 64.1% of medical students felt it would be unacceptable (p<.05). No statistically significant difference was found if this image were posted by medical students, residents, or faculty. Vignette #3 was a picture of the text Im not an alcoholic. Im a drunk. Alcoholics go to meetings. If a premedical student posted this, 75.3% of faculty and 54.9% of medical students felt it would be unacceptable (p<.01). No statistically significant difference was found if this image were posted by medical students, residents, or faculty. Vignette #4 was a picture of a woman drinking from a large bottle of liquor. If a premedical student posted this, 69.1% of faculty and 51.5% of medical students felt it would be unacceptable (p<.05). No statistically significant difference was found if this image were posted by medical students, residents, or faculty. Vignette #5 was a picture of a woman holding a bottle of beer and positioned in a provocative pose. Statistically significant differences were found among faculty and medical students at all levels of learners. 48.7%, 49.5%, 59.7%, and 67.8% of faculty and 31.2%, 38.1%, 50%, and 58% of medical students felt it would be unacceptable for this to be posted by premedical students, medical students, residents, and faculty, respectively.
CONCLUSION: This study illustrates the lack of consensus on what constitutes professional behavior amongst medical students and attending physicians. Prior studies have suggested that generational differences do exist when it comes to perceptions of professionalism. Data derived from this study supports the idea that generational differences may play a role in perceptions of professionalism when applied to activities outside the workplace. As social media sites such as Facebook become more ubiquitous, there will be increasing challenges in the education of physicians-in-training about issues related to medical professionalism compounded by the
fact that perceptions of professionalism differ between educators and trainees.
MONITORING OF PRIMARY HEALTH CARE IN A FEE-FOR-SERVICE WITH UNIVERSAL COVERAGE COUNTRY: THE SWISS CHEESE SITUATION Nicolas Senn 1; Jacques Cornuz1. 1Department of Ambulatory Care and Community Medicine, University of Lausanne, Lausanne, N/A. (Tracking ID # 10874)
BACKGROUND: Monitoring primary health care (PHC) is essential for public health, health authorities and care providers in order to achieve a high quality of efficient care (at best cost). Switzerland has a unique consumer-driven fee-for-service with universal coverage health system regulated by the health authorities. Very few studies have attempted to describe the Swiss PHC system and none have looked at the feasibility of using existing standardized indicators. We investigated the challenges of applying an international monitoring tool for PHC in Switzerland and compared with the US situation, since these two countries have been labeled as the Sister Republics (Hutson JH, The Library of Congress, 1991)
METHODS: We analyzed the strengths and weaknesses of the Swiss PHC system by practicing a standard monitoring tool developed for Europe called PHAMEU (Primary Health Care Activity Monitor for Europe, http://www.phameu.eu
Web End =www.phameu.eu). We investigated the availability and quality of data and identified the indicators most relevant to describe the Swiss PHC health system with reference to the US situation. All collected data refer to the period 2005 to 2009.
RESULTS: From the 91 PHAMEU project indicators, 37 (41%) were built on directly available data, 14 (15%) required major adaptations of existing data and 40 (44%) were based on expert opinion as no data were available. Whereas 33 out of 39 (85%) indicators describing the structure of PHC (governance, economics and work-forces) relied on existing data, only 7 out of 37 (19%) indicators describing the process of PHC (access, continuity physician-patient, coordination and comprehensiveness) were based on existing data. Slightly more than half (55%) of the available information came from the governmental sector, 33% came from PHC providers, 10% came from private health insurances and 2% came from other sources. The most relevant

indictors describing the Swiss PHC system were the following: 1) 99.2 % of the population is covered by health insurance (US: 85%) 2) 26% (15 b$) of health expenditures was spent on PHC (US: no comparable data available). 3) 2.3% was spent on prevention (US: 3%) 4) 63% of private practices are single handed (US: 27%). 5) Number of GP visits per year and per capita was 2.8 (US: 1.5). 6) Mean duration of PHC consultation was 17 minutes (US: 21 minutes). 7) 3.2% of the time of consultations was spent for home visits. 8) 5.8% of the time of consultation was spent for telephone.
CONCLUSION: In Switzerland, which has a consumer-driven fee-for-service with universal coverage health care system, almost half of data were not available to built standard indicators for monitoring PHC. The information describing the operational activities of PHC is dramatically lacking especially in regards to the health status of patients, health care management and patients satisfaction. This might reflect the relative autonomy of PHC providers in their practice, which are predominantly single handed compared to the United

Sates where less than 30% of practices are single-handed. It seems however urgent to implement information systems to fill these Swiss cheese holes.
SUBCLINICAL THYROID DYSFUNCTION AND THE RISK OF HEART FAILURE, OTHER CARDIOVASCULAR EVENTS AND MORTALITY IN THE ELDERLY David Nanchen 1; Jacobijn Gussekloo 1; Rudi G.J. Westendorp 1; David J. Stott 2; J.Wouter Jukema 1; Stella Trompet 1; Simon P. Mooijaart 1; Nicolas Rodondi 3; Anton J.M. de Craen1. 1Leiden University Medical Center, Leiden, N/A ; 2University of Glasgow, Glasgow, N/A ; 3Department of Ambulatory Care and Community Medicine, Lausanne, N/A. (Tracking ID # 10877)
BACKGROUND: Mild thyroid dysfunction is common in older people. However the clinical importance is uncertain. We aimed to determine the extent to which subclinical hyper- and hypothyroidism influence the risk of common diseases in elderly people, including heart failure, atrial fibrillation, cerebrovascular and cardiovascular events or mortality.
METHODS: We studied 5748 men and women aged 7082 years with known cardiovascular risk factors or previous cardiovascular disease, but free of heart failure and atrial fibrillation in the Prospective Study of Pravastatin in the Elderly at Risk (PROSPER) trial. In multivariate adjusted Cox proportional hazard models, we compared the risk of incident heart failure hospitalization, atrial fibrillation, cerebrovascular and cardiovascular events or mortality over a 3.2-year follow-up. Thyroid status was established at study baseline. Euthyroid participants (defined as
thyroid stimulating hormone [TSH] level 0.45-4.5 mIU/l) were compared with those with subclinical hyperthyroidism (TSH <0.45 mIU/l with normal free thyroxine) and those with subclinical hypothyroidism (TSH >4.5 mIU/l with normal free thyroxine). RESULTS: The mean age of the study population was 75 (SD 3.3). The prevalence of cardiovascular disease was 44% at study baseline. Subclinical hyperthyroidism was present in 234 participants (4.1%) and subclinical hypothyroidism in 466 participants (8.1%) at baseline. There was no difference in prevalence of diabetes or known cardiovascular disease by thyroid status at baseline. During the 3.2-year follow-up, the incidence of heart failure hospitalization was higher in elderly adults with subclinical hyperthyroidism compared to the euthyroid group, with 25 vs 12 events per 1000 person-years (multivariate adjusted hazard ratio 2.61, 95% confidence interval, 1.59-4.26, p<0.01 (see Figure). The risk of heart failure dependant of thyroid function was similar in adults with endogenous subclinical hyper-thyroidism, with or without pre-existing cardiovascular disease, or those under pravastatin or beta-blocker therapy, but increased with increasing heart rate (p for trend 0.043). We found no association between subclinical hypothyroidism and heart failure. There were no consistent association between subclinical thyroid dysfunction and the risk of atrial fibrillation, cerebrovascular and cardiovascular events or mortality.
CONCLUSION: Subclinical hyperthyroidism is an independent risk factor for heart failure in elderly adults, particularly in those with an elevated heart rate. Randomized controlled trials of treatment of subclinical

hyperthyroidism to prevent heart failure in older people are warranted.

COMPUTED TOMOGRAPHY ASSOCIATED CANCER AND CANCER DEATHS FROM EMERGENCY DEPARTMENT VISITS IN THE US Leah Zallman 1; Steffie Woolhandler 2; David Himmelstein 2; David Bor 3; Danny McCormick1. 1Cambridge Health Alliance, Cambridge, Massachusetts ; 2Cambridge Health Alliance/City University of New York School of Public Health, Cambridge, Massachusetts ; 3Cambridge Health Alliance, Jamaica Plain, Massachusetts. (Tracking ID # 10895)
BACKGROUND: Computed tomography scan (CT) use has increased substantially in the past decade. Although CTs offer distinct diagnostic advantages, their widespread use raises concern about iatrogenic cancer. Little is known about the number of cancers and cancer-related deaths caused by CT scans during the evaluation of adults- patients in U.S. emergency departments (EDs).
METHODS: We estimated the lifetime attributable risk of cancer and cancer related deaths caused by CT use during the evaluation of adult patients in US EDs annually and the frequency of, trends in and factors associated with CT use in this setting. We conducted a cross sectional analysis of CTs performed during ED visits by adults in a nationally representative sample using the National Hospital Ambulatory Medical Care Survey (NHAMCS), 19982008. We used the Biologic Effect of Ionizing Radiation VII model to estimate the lifetime attributable risk of cancer incidence and mortality based on age at exposure, gender, and effective dose estimates for all adult visits to US EDs during which a CT was performed in 2008. Because the NHAMCS does not provide details of CTs ordered (i.e. abdomen vs chest, single or double pass), we calculated the effective dose using the National Emergency Department Sample, which provides nationally representative estimates of the proportion of CTs performed on each body area(i.e. chest, abdomen) and the number of passes through the CT scanner for ED patients. We also established the proportion of visits for which CTs were performed from 1998 and 2008 and conducted multivariate logistic regression analysis to determine patient and hospital characteristics associated with CT usage in 2008. In order to determine whether potential increases in rates of CT use over time were associated with improved detection of severe or occult disease that require hospital admission, we compared the proportion of hospital and intensive care unit admissions per CT each year from 1998 to 2008 with a chi-square trend test. If increases in CT use were not associated with improved detection of severe disease requiring hospital or intensive care unit admission, we would expect this ratio to decline over time.
RESULTS: In 2008, 16,406,921 CTs were performed nationally during adult ED visits; we estimate that these will cause 3750 (95% CI 3570 3940) cancers and 1994 (95% CI 19042088) cancer deaths in future years. The proportion of adult ED visits during which a CT was performed increased from 4.8% (95% CI 4.4-5.1) to 17.1% (95% CI16.0-18.2) between 1998 and 2008, a 335% increase. Older age, triage time of <15 minutes, and evaluation at an urban hospital were independently associated with higher odds of receiving a CT. The proportions of hospital and intensive care unit admissions per CT fell from 2.69 (95% CI 2.69-2.69) to 0.95 (95% CI 0.95-095) (p=0.0019) and from 0.28 (95% CI 0.28-0.28) to 0.12 (95% CI 0.12-0.12) (p=0.0093), respectively.
CONCLUSION: While the net number of lives saved by CT use in the EDs is not known, the large number of cancers and cancer deaths attributable to CT use, as well as the large increase in CT use without an associated increase in admission rates, highlight the importance of curbing unnecessary CTs in the ED setting.
NEEDLE AND SYRINGE EXCHANGE PROGRAMS IN CORRECTIONAL SETTINGS: FEASIBLE, SAFE AND NECESSARY! Hans Wolff 1; Thierry Favrod-Coune 2; Jean-Pierre Rieder 2; Francoise Pinault 2; Laurent Getaz 2; Barbara Broers2. 1University Hospitals of Geneva, GENEVA, N/A; 2University Hospitals of Geneva and University of Geneva, Geneva, N/A. (Tracking ID # 10899)
BACKGROUND: Addiction-related problems are highly prevalent in almost every prison in the world. Despite

the fact that illicit drugs are forbidden, they frequently enter most correctional facilities. Therefore, harm reduction measures such as needle and syringe exchange programs (NSP) need to be implemented. In the community and in prison, NSPs have been shown to: 1. prevent the transmission of infectious diseases, 2. not compromise the security (syringes not used as a weapon) and 3. not increase the consumption nor the injection of drugs. Despite strong evidence of efficacy, NSPs exist in less than 1% of the prisons worldwide. The Geneva University Hospitals are dispensing health care to inmates of the prison of Geneva, the largest remand prison in Switzerland. This prison faces severe overcrowding as it housed in 2010 a mean of 543 inmates, primarily male, in the 270 officially provided places (occupancy rate: >200%). The NSP is in place since 1996. The aim of the study is to evaluate the acceptance and feasibility of the NSP in prison.
METHODS: In the prison of Geneva, a syringe exchange protocol was elaborated by addiction specialists and accepted by the prison authorities in 1996. The protocol gave an official framework to provide injection kits and appropriate counseling to drug-using inmates. Staff is trained in addiction and harm reduction measures. Evaluation included distribution and return of the syringes over time.
RESULTS: Each year 169446 syringes were distributed to 2453 intravenous drug using inmates (fig 1). The return rate ranged from 58 to 83%. No acts of aggression or other incidents involving the contents of injection kits (e.g. threats, aggression, injury by a syringe left in a dustbin) were reported. The program was well accepted by the prison staff and the health care team. Healthcare workers noted that 10-20% of the iv-drug users participating in the program related an initial hesitation when distributing the syringes, which let suspect that the fear of denouncement existed and that the totality of the target prisoners were not reached. The prison direction actively supported the program and operated no cell search for drugs after delivery of an injection kit. In addition to the harm reduction itself, the program helped to strengthen the dialogue in an atmosphere of greater understanding and encouraged constructive co-operation between all partners (healthcare team, prison officers, and political partners).
CONCLUSION: Scientific evidence as well as our experience showed that syringe and needle exchange in the prison is feasible, safe and well accepted by staff and iv-drug users, although it could be improved by providing better confidentiality during the distribution of the injection kits. The program needed an active supervision to make sure that nurses, prison staff and detainees feel comfortable with it. Access to harm reduction measures should be universal, in concordance with human rights principles and therefore be implemented in all prisons.

DELIVERY, UPTAKE, AND SATISFACTION WITH DECISION SUPPORT INTERVENTIONS IN A PRIMARY CARE CLINIC Carmen L Lewis 1; Leslie Stewart 1; Shaun McDonald 1; Kim Young-Wright 1; Robert Malone 1; Christopher P DeLeon 1; Michael P Pignone1.
1University of North Carolina - Chapel Hill, Chapel Hill, North Carolina. (Tracking ID # 10904)
BACKGROUND: Patient centered care is an important component of quality medical care. Employing decisions support interventions is a means of promoting patient centered care by encouraging patient to be more actively engaged in their medical care. However, implementation of decision support interventions in primary care poses a number of challenges including the timing of delivery to maximize uptake and effectiveness and the logistics of integrating the program into existing clinic operations. Our purpose was to implement decision support interventions for a wide variety of health conditions in primary care practices and to test the effectiveness of this program in terms of patient uptake and satisfaction.
METHODS: We employed health information technology (HIT) to identify patients who are potentially eligible for decision support using ICD-9 diagnosis codes and billing information. For patients who were due for CRC screening, staff mailed decision support several weeks prior to the patients upcoming appointment. For in-clinic delivery, we employed continuous quality improvement methodology to modify nurse work processes to assess patient eligibility for and interest in targeted
decision support interventions by administering a computer-based survey during their intake evaluation.

Decision support was then provided by care assistants according to patient preference (DVD and booklet provided in clinic vs. mailed after the visit). During follow up appointments nurses were also triggered to collect information about patient uptake and satisfaction with decision support interventions. RESULTS: From 8/10 to 11/10 we delivered decision support to 433 eligible patients for screening (236 for colorectal cancer (CRC) and 5 for PSA screening), symptomatic conditions (46 for hip and 42 for knee osteoarthritis, 46 for chronic pain, 2 for depression, 9 for menopause, 9 for benign prostatic hyperplasia), and chronic conditions (28 for diabetes, and 10 for weight loss surgery). Over this period, clinic staff follow-up on 532 patients who had been provided decision support within 6 months of their clinic visit. Of these patients, 363 (68%) indicated that they had received a decision aid. Among this 363 patients, 302 (83%) liked receiving the decision aid, 295 (81%) found the information useful, 209 (58%) watched some or the entire DVD, and 239 (67%) read some or the entire booklet. Patients were more likely to report that they liked receiving the decision support (88% vs. 79% p=0.03), more likely to watch the DVD (66% vs. 51% p<0.01) orread the booklet (72% vs. 59%; p=0.02) for symptomatic conditions (n=134) compared to screening (CRC) (n=197). Similarly, those who received decision support in clinic (n=168) were more likely to report they liked getting it (90% vs. 77% p<0.01) more likely to watch it (67% vs. 50%; p<0.01) and more likely to read the booklet (74% vs. 58%; p<0.01) than those who were mailed decisions support (CRC screening) before their upcoming visit.

CONCLUSION: We were able to deliver a wide variety of decision support interventions and the majority of patients reported receiving them. Uptake and satisfaction appeared to vary by topic type and delivery method.

SHORT LENGTH OF STAY IS ASSOCIATED WITH INCREASED MORTALITY William Southern 1; Julia Arnsten2. 1Albert Einstein College of Medicine/Montefiore Medical Center, Sleepy Hollow, New York ; 2Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York. (Tracking ID # 10906)

BACKGROUND: Since the introduction of the prospective payment system (PPS) in 1983, hospitals in the U.S. have been financially incentivized to shorten inpatient length-of-stay (LOS), and LOS has shortened dramatically. However, it is unclear if reducing LOS adversely affects patient outcomes, such as hospital readmission and mortality. Given financial pressures to shorten LOS, it is possible that some patients may be discharged too early, and that premature discharge is associated with poor patient outcomes. Previous attempts to examine associations between LOS and patient outcomes have generally been confounded by patient-level factors. In particular, because LOS is closely associated with disease severity, patients with shorter lengths-of-stay tend to be less severely ill than patients with longer lengths-of-stay. We used a unique study design to examine associations between LOS and outcomes of care. Our analysis was based on physician LOS tendencies, which were determined for each physician and then used to group hospital admissions and assess associations with mortality and readmission. METHODS: We examined all admissions to the medical teaching service of an urban medical center from 7/1/02 through 6/30/08. First we calculated the mean LOS for each physician during the study period; this defined each physicians LOS tendency. Next, each physician was designated a long-LOS or a short-LOS physician defined by the median LOS for all physicians. Then we created two admission groups, which we defined according to the physician to whom the admission had been assigned. We then compared admissions assigned to long-LOS physicians vs. short-LOS physicians with respect to baseline admission characteristics (demographic characteristics, insurance, Charlson co-morbidity score, admission laboratory values, Laboratory-based Acute Physiology Score (LAPS), and diagnoses), physician characteristics (# of admissions, hospitalist vs. non-hospitalist, years since licensure, years since graduation, and US vs. international medical school) and 30-day mortality and readmission rates. Next, we constructed logistic
regression models to assess the independent association between physician LOS tendency, and patient

outcomes after adjustment for patient-level and physician-level covariates. To address the threat of residual confounding, we used a propensity score model to match admissions assigned to long-LOS physicians with those assigned to short-LOS physicians with respect to demographic characteristics, insurance, Charlson co-morbidity score, admission laboratory values, Laboratory-based Acute Physiology Score (LAPS), and discharge diagnoses. Each admission assigned to a short-LOS physician was matched to one admission assigned to a long-LOS physician using a greedy, nearest neighbor matching protocol. Finally, we constructed univariate and multivariate conditional logistic regression models to assess the independent association between physician LOS tendency and patient outcomes in the matched patient groups.
RESULTS: 26,445 admissions and 79 physicians were examined. 7380 admissions were assigned to long-LOS physicians, and 19,065 admissions were assigned to the short-LOS physicians. Admission groups were similar with respect to age, sex, insurance type, admission creatinine, Charlson score, and discharge diagnoses. Admissions assigned to short-LOS physicians were more likely to be Black, and had a higher mean LAPS score. Short-LOS physicians saw more total admissions, and were more likely to be hospitalists, have fewer years of licensure, and fewer years since graduation. After propensity score matching, the patient groups were similar with respect to all demographic and clinical characteristics. In unmatched analysis, care by a short-LOS physician was not significantly associated with 30-day mortality (OR 1.07, 95% CI: 0.94-1.22). After adjustment for demographic and clinical patient characteristics care by a short-LOS physician was associated with increased risk for 30-day mortality, but the difference was not significant (OR 1.13, 95% CI: 0.97-1.32). After propensity score matching, care by a short-LOS physician was associated with significantly increased risk for 30-day mortality (OR 1.18, 95% CI: 1.02-1.37) which remained after adjustment for physician characteristics (Or 1.19, 95% CI: 1.01-1.40). (Table) Care by a short-LOS physician was not associated with increased risk of readmission in unadjusted (OR 1.03, 95% CI: 0.96-1.11), adjusted (OR 1.03, 95% CI: 0.95-1.12), propensity score matched (OR 1.03, 95% CI:0.94-1.12), or matched and adjusted analyses (OR 1.04, 95% CI: 0.94-1.14).
CONCLUSION: We used a unique study design to examine associations between physician LOS tendency and mortality. Compared to admissions assigned to physicians with longer LOS tendencies, admissions assigned to physicians with shorter LOS tendency had higher 30-day

mortality. It is unclear why assignment to short-LOS physicians was not associated with increased risk for readmission. However, we were unable to capture readmissions to hospitals outside our system, and it is possible that patients discharged after short LOS were more likely to seek readmission elsewhere, biasing our results. Future studies should apply this study design to a larger sample size to better assess the association between physician length of stay tendency and patient outcomes.

FEASIBILITY OF UTILIZING AN ALL-VOLUNTEER WORKFORCE OF SUCCESSFUL WEIGHT LOSERS TO ADDRESS THE US OBESITY EPIDEMIC

Jennifer L. Kraschnewski 1; Christopher N. Sciamanna1.
1Penn State Milton S. Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 10914)
BACKGROUND: Though most adults are able to lose weight if they try, few are able to maintain that loss without ongoing support. Long-term, sustained interventions have been shown to improve weight loss and delay weight gain. However, given that overweight and obesity affect 2 out of 3 Americans, any potential intervention needs to be highly cost-effective. Laypersons (i.e. peers) have demonstrated effectiveness in leading groups for individuals interested in weight loss, although studies have not assessed using successful unpaid volunteers. In addition, nearly one in 6 US adults has successfully lost at least 10% of their weight and kept it off for at least one year. In this study, we examine the possibility of utilizing an all-volunteer workforce to help address the obesity epidemic.
METHODS: We used data from a survey of a nationwide panel of adults (Knowledge Networks, Inc.) with a response rate of 83%. The analytic sample consisted of 673 men and women who completed the online survey in February 2010. Of the 673, 133 (19.7%) participants were not overweight (BMI >25.0) at their maximum

weight, so were excluded from these analyses. Participants were asked about their weight history using items from the National Health and Nutrition Examination Survey (NHANES) Weight History Questionnaire and the Behavioral Risk Factor Surveillance System (BRFSS). Survey items were created to identify participant interest in three specific types of weight control programs: a free program led by successful peers, a program that was not free and led by a successful peer, and a more traditional program led by trained paid professionals. Interest was assessed using a 5-point Likert-type scale and question order was varied randomly. We additionally created a survey item to assess participant interest in leading a weight control group, which was asked of successful peers, defined as individuals who had ever lost at least 10 pounds. Participants were also asked about any prior volunteering. Multiple logistic regression models assessed: (1) the association of participant characteristics with preference for an unpaid successful volunteer group leader over a paid expert, and (2) the association of participant characteristics with likelihood of willingness to volunteer to lead a weight control group. All models controlled for demographics (age, gender, race/ethnicity, education level, household income), weight history, weight loss intention, and medical history (overall health status, hypertension, diabetes). RESULTS: The sample had the following characteristics: 45.5% were female,16.2% were at least 65 years old, 31.3% were college graduates, and 50.8% had a household income of greater than $50,000. The majority of participants(61.3%) reported currently trying to lose weight and most (85.9%) had lost at least 10 pounds once in the past. Though most (51.6%) participants had no preference between the peer-led free program and expert-led paid program, nearly half (44.5%) preferred the peer-led free program. Only 3.9% of participants preferred the expert-led paid program. After controlling for demographics, weight history, medical history and weight loss intention, the only variables associated with a preference for a peer-led free program, versus an expert-led paid program, was a recent personal experience with a weight control program (adjusted OR 2.2, 95% CI 1.1-4.5) and experience as a
volunteer (adjusted OR 2.2, 95% CI 1.3-3.8). Of the individuals with prior weight loss success (n=540), 14.7% were willing to volunteer to meet with a group of people to help them control their weight (i.e. answered strongly agree or agree). In multivariable analyses, willingness to be a group leader in a peer-led free program was associated with BMI category, recent personal experience with a weight control program and experience as a volunteer. Those who had a BMI in the 18.5-24.9 (normal weight) and 25.0-29.9 (overweight) ranges were 0.1 times (95% CI 0.0-1.0) and 0.2 times (95% CI0.0-1.0) as likely, respectively, to be interested in being a group leader than those with a BMI >40.0 (morbidly obese). Individuals who recently participated in a weight loss program were 0.3 times as likely to be willing to lead a group (95% CI 0.1-0.9). Those who reported ever volunteering for an organization were 14.6 times (95% CI 4.4-48.2) more likely to be interested in being a group leader than those who did not report volunteering. CONCLUSION: Overall, participants appear to be much more interested in a free weight control program led by peers, compared to traditional programs (expert-led) or programs led by peers for which they are required to pay. In addition, one in 7 individuals with prior success at weight loss would be willing to volunteer to lead weight control groups, suggesting a feasible work-force for this type of intervention. Interest in volunteering to lead such a program amongst those who have been successful at weight loss was associated with prior experience with volunteerism. This may mean that using existing hospital volunteering programs as recruitment vehicles may be useful for identifying potential volunteers. Further research is necessary to determine the effectiveness of a volunteer-led weight control program.

HEPATITIS B: PREVALENCE, RISK FACTORS AND KNOWLEDGE OF TRANSMISSION MODES AMONG INMATES IN A SWISS PRISON Laurent Getaz 1; Hans Wolff1. 1University Hospitals of Geneva, Geneva, N/A. (Tracking ID # 10917)

BACKGROUND: Hepatitis B (HBV)-infection continues to be a substantial problem worldwide despite the existence of a safe and effective vaccine. HBVis transmitted within prison settings, but also after release, because of resumption of drug use and sexual activity. Preventive programs in prison can reach many high-risk individuals. This study aimed to estimate the prevalence of HBV infection and its associated factors as well as

the knowledge of transmission modes among inmates of Genevas Champ-Dollon prison, which is Switzerland largest remand prison. METHODS: A total of 116 individuals were interviewed using a standardized questionnaire on sociodemographic characteristics and HBV knowledge. All accepted blood samples. HBV surface antigen (HBsAg), antibodies against surface antigen (HBsAb) and antibodies against core antigen (HBcAb) were detected by enzyme immunoassay. RESULTS: This prison population was characterized by a high proportion of young male migrants: 36% originating from Eastern Europe, 32% from sub-Saharan Africa and 22% from North Africa; 64% were illegal immigrants without health insurance.
Prevalence for HBcAb indicating past or current infection was 44% (95% CI: 34.9-53.0) and 4.3% (95%CI: 1.4-9.8) had HBsAg indicating current infection. Eleven percent (95%CI: 5.5-17.0) of inmates had only HbsAb, suggesting former vaccination.
Region of origin is significantly associated with HBV infection ($p<0.00001$): 75.7% (28/37) of inmates from sub-Saharan African were HBcAb positive (95% CI 61.8-89.5), 40.5% (17/42) from Eastern Europe (95% CI 25.6-55.3) and 12% (3/25) from North Africa (95% CI 2.5-31.2). Age 27 years or older was also significantly associated with infection ($p=0.035$). On stratified analysis, origin and age remained significantly associated with HBV infection.
Eleven percent (4/37) of inmates from sub-Saharan Africa and 1.3% (1/79) of those from other origins were HBsAg positive ($p=0.038$).

Only 1 of 5 inmates (20%) suffering current infection (HBsAg positive) was aware of his infection.
A minority of inmates was aware that HBV can be transmitted through unprotected sex (24%), sharing needles (26%), sharing razor (21%) and tattooing (19%). Inmates not originating from Western Europe had the worst knowledge of transmission modes ($p=0.003$).
CONCLUSION: Prevalence of current HBV infection was 14 times higher than in the Swiss general population and also higher than in U.S. prisons. The high prevalence (4.3%) combined with the ignorance of infection and the lack of knowledge of transmission modes underlines the need for action to limit the risk of HBV in this population. The main risk factor found in our study was the geographical origin of the inmates. Differences in the prevalence of HBV by world regions reported by the CDC corroborate these results.
Two-thirds of the inmates were illegal immigrants in Switzerland, who had no health insurance and thus no access to community immunization program. A serological screening of populations characterized by high HBV prevalence would enable the implementation of an intensive educational program targeting contagious and susceptible inmates. When relevant, appropriate treatment could be provided. Persons tested positive for past or current infection could be excluded from vaccination thus leading to substantial reduction of costs.
Prison settings provide unique opportunities to vaccinate this high risk population. Vaccinating incarcerated persons protects not only those individuals, but also the community at large.

DISPARITIES IN SURGERY FOR EARLY STAGE LUNG CANCER: AN ANALYSIS OF MORTALITY ONE YEAR AFTER DIAGNOSIS

Samuel Cykert 1; Giselle Corbie-Smith 2; Peggye Dilworth-Anderson 3; Michael Monroe 4; Franklin McGuire 5; Paul Walker 6; Lloyd Edwards3.
1University of North Carolina, Chapel Hill, Chapel Hill, North Carolina ;
2University of North Carolina- Chapel Hill, Chapel Hill, North Carolina ;
3UNC-CH, Chapel Hill, North Carolina ; 4Carolinas Medical Center, Charlotte, North Carolina ; 5USC School of Medicine, Columbia, South Carolina ; 6ECU -Brody School of Medicine, Greenville, North Carolina. (Tracking ID # 10927)
BACKGROUND: Our recent, prospective cohort study confirmed reports of administrative data showing that African-Americans (AA) with early stage, non-small cell lung cancer do not receive potentially curative surgery

as often as similar white patients (W). We also found that comorbid illnesses and lack of a regular source of care were factors associated with less surgery for AA but not W patients. Poor perceptions of communication predicted lower surgical rates for all. We now report an analysis of outcomes one year after diagnosis and examine whether racial differences are associated with one year mortality in this cohort or whether other factors explain mortality differences.
METHODS: Using pulmonary, oncology, thoracic surgery, and generalist practices in 5 communities, we enrolled 437 newly diagnosed patients with early stage, non-small cell lung cancer. Inclusion criteria were as follows: patients were required to be at least 18 years old, have a tissue diagnosis or >60% probability of non-small cell lung cancer using Bayesian methods, and be limited to Stage I or II disease by clinical and radiological testing. Patients were identified from direct referral from practices or through the utilization of a chest CT review protocol. After being informed of the diagnosis of probable or definite lung cancer, but before the establishment of a treatment plan, patients were administered a 100-item survey. Chart reviews were performed 4 months after enrollment to assess comorbidities, pulmonary function tests, and treatment with surgery. Mortality data were obtained by personal or family contact and death certificates 1 year after enrollment. Regression analyses were performed with one-year mortality as the primary outcome.
RESULTS: Of the 437 patients enrolled, 386 were eligible for lung cancer surgery based on diagnostic stage and absence of absolute contraindications. Eighty-eight percent had the diagnosis confirmed pathologically. Of those patients enrolled, 29% were AA, 90% had health insurance, and the median age was 66 years. The one-year mortality rate for the cohort was 17% (N=66). Although mortality was similar according to race (AA 17%, W 17% p=0.9), AA were, on average, 4.4 years younger at the time of death compared to W (66.9 vs. 71.3 years). The one-year mortality for surgically treated patients was 12% compared to 25% for the no surgery group (p=.002). Regression analysis revealed that age over 66 (OR 3.4, 95% CI 1.8-6.6) and 2 comorbid illnesses (OR 2.8, 95% CI 1.2-6.4) were associated with worse mortality while surgical treatment (OR .52, 95% CI .29-.93) was protective. Race, income, education, marital status, gender, and regular source of care were not associated with one-year mortality. CONCLUSION: Older age and comorbid illnesses are associated with one-year mortality in early stage lung cancer. Although African-Americans receive lung cancer surgery less often than white patients, it is surgical treatment, not race, that is associated with survival.
RACIAL/ETHNIC DISPARITIES IN HYPERTENSION FOLLOW-UP CARE OF HEALTH CENTER PATIENTS
Quyen Ngo-Metzger 1; Ravi Sharma 1; Leiyu Shi 2; Seiji Hayashi 1; Charles Daly 1; Robert Politzer3.
1Health Resources and Services Administration, Rockville, Maryland ;
2Johns Hopkins School of Public Health, Baltimore, Maryland ;
3Consultant, Columbia, Maryland. (Tracking ID # 10928)
BACKGROUND: Racial ethnic minorities, especially African Americans, are more likely to have hypertension and suffer from increased morbidity and mortality compared to Whites. Federally Qualified Health Centers (Health Centers) supported by the Health Resources and Services Administration, care for over 18 million patients, 63% of whom are racial/ethnic minorities. For Health Center patients with hypertension, we assessed the presence and magnitude of racial/ethnic disparities in obtaining counseling or training to help manage hyper-tension, hospitalizations, or ER visits due to hypertension, and self assessed confidence in ability to self manage hypertension. METHODS: Cross-sectional analyses using the 2009 Health Center Patient Survey, a nationally representative sample of 4,558 patients seen at a Health Center in the last 12 months. After examining the prevalence of hypertension in the full sample, we focus on the subset who self-report hypertension (n=1764) including 522 non-Hispanic white, 575 African American, and 602 Hispanic patients. We estimated logistic regression models to predict the likelihood of obtaining each of the following: health professional advice about diet, salt, exercise, and alcohol; patient compliance with advice; training on patient self management by a nurse; hospital or ER episodes in past 2 years due to hypertension; and confidence in capacity to self-manage hypertension. In our models, we controlled for patient characteristics including the

presence and source of health insurance coverage, comorbidities, income, employment, self-reported health status, gender, age group, and other factors.
RESULTS: Among all health center patients, both African Americans and Hispanics are more likely to have hypertension compared with White patients (OR=2.90 (2.30, 3.65) and OR=1.31 (1.05, 1.62) respectively). Among hypertensive health center patients, there are no racial/ethnic disparities favoring Whites evident in the receipt of counseling on lifestyle (diet, salt, exercise and alcohol) or compliance with counseling (for example, receipt of advice to change diet: African Americans OR=1.64 (1.27, 2.13), Hispanics OR=1.32 (1.03, 1.71); compliance with diet advice: African Americans OR=1.65 (1.28, 2.14), Hispanics OR=1.30 (1.01, 1.69)). In

addition, no disparities exist in receipt of hypertension self-management training by nurses (African Americans OR=2.46 (1.82, 3.33); Hispanics OR=1.71 (1.26, 2.33)). African Americans are more likely than other racial/ethnic groups to be hospitalized or visit the ER in the past 2 years due to hypertension (OR=1.50 (1.07, 2.11)). Hispanics are less likely to express confidence in their capacity to self-manage hypertension relative to other racial/ethnic groups (OR=0.56 (0.42, 0.74)).
CONCLUSION: Among Health Center patients with hypertension, there are no apparent racial/ethnic disparities in patients receipt of counseling or self-management training provided by a health center professional. However, disparities exist for hospitalization/ER use and self-efficacy for hypertension control. These results persisted after controlling for a number of important patient clinical and demographic characteristics. Health centers, like other settings, need to address potentially avoidable acute care usage due to hypertension by implementing better care coordination and improving patient self-management. A more aggressive educational and outreach program may lead to greater self-efficacy for hypertension self-management.
RESULTS OF THE IMPROVING PERFORMANCE IN PRACTICE PROGRAM: IMPROVING PRIMARY CARE THROUGH PRACTICE COACHING AND IMPROVEMENT NETWORKS Erin Elizabeth Van Scoyoc 1; Kevin Stanford 2; Peter Margolis 2; Darren DeWalt3. 1UNC Chapel Hill, Chapel Hill, North Carolina ; 2Cincinnati Childrens Hospital Medical Center, Cincinnati, Ohio ; 3University of North Carolina at Chapel Hill, Chapel Hill, North Carolina. (Tracking ID # 10929)
BACKGROUND: Optimal strategies for widespread primary care transformation are unknown. One challenge to scale up is how to design programs to address variation in the organizational or contextual factors that may be associated with successful quality improvement (QI) efforts. The Improving Performance in Practice (IPIP) initiative is a program of the primary care specialty societies and boards that aims to improve the pace and success of primary care transformation efforts and establish ongoing improvement networks. The IPIP program assists states in developing regional ambulatory care quality initiatives that support practices in undertaking routine performance measurement and data sharing, education in QI methods and clinical content, and the creation of networks of practices to share the ideas and work of improving care. State programs also provide on-site practice coaching to facilitate the improvement process. IPIP enrolled its first practices in 2006, and is currently active in seven states, with more than 350
participating practices. The objective of this study is to investigate whether practices that have participated in the IPIP program have improved the quality of care for patients with diabetes, and to determine if practice characteristics influenced the pace of improvement.
METHODS: Practices participating in the IPIP program submit monthly performance reports on standardized measures. We studied practices reporting the following diabetes measures: percent of diabetic patients in the practice with: A1c >9%, systolic blood pressure (SBP) <130 mmHg, LDL <100 mg/dL, an eye exam, smoking cessation counseling, a foot exam, and testing or treatment for nephropathy. We included all practices that had participated in the IPIP program for at least six months prior to November 2009, and excluded practices that did not focus on diabetes, and practices that used a convenience consecutive sampling method for data reporting. We used linear regression to determine the mean rate of change over time for each measure, and estimated the

projected improvement over 12 months based on the mean rate of change per month for each measure. We then compared the rate of improvement by practice characteristics including: practice size (number of provider FTEs), presence of an electronic health record (EHR), prior experience with quality improvement, initial performance, and number of months participating in the IPIP program. RESULTS: 165 practices participating in the IPIP program were included. 33% of practices were in Pennsylvania, 32% in Colorado, 23% in North Carolina, and 12% in Michigan. 64% of practices had less than or equal to 3 FTEs. 49% had an EHR in place, and 22% reported prior experience with quality improvement. 46% had participated in IPIP for more than 12 months. Practices participating in the IPIP program improved significantly in all of the measures except for the blood pressure and cholesterol goals (SBP< 130 mmHG and LDL<100 mg/dL).(Figure 1) Practices with worse initial performance improved faster than those with better initial performance ($p<0.01$ for all of the diabetes measures). Presence of an electronic health record, prior experience with QI, and practice size did not impact the rate of improvement ($p>0.05$ for all of the diabetes measures). CONCLUSION: Practices participating in the IPIP program improved the quality of care for their patients with diabetes. Improvement was faster in practices with worse initial performance. Creating networks of practices can be an effective model to disseminate quality improvement to community primary care practices. Consistent, frequent measure reporting across a large number of practices, combined with information on practice context and facilitation, can help to understand factors that expedite translation of evidence into practice. Such an improvement infrastructure can also lead to more rapid adaptation of the practice support strategies.

HOUSING AND CASE MANAGEMENT DECREASE HOSPITALIZATIONS AMONG FREQUENT USERS OF HOSPITAL SERVICES: A PILOT STUDY Laura Zimmermann 1; David Buchanan 2; Lou Rohr3. 1; 2Erie Family Health Center, Chicago, Illinois; 3Rush University Medical Center, Chicago, Illinois. (Tracking ID # 10936)

BACKGROUND: Homeless individuals utilize the heath care system often and at great expense. Although some of these individuals have complex medical needs requiring intensive support, others have complex social needs which require supportive housing and case management. In some cases, the increased use of health services is a symptom of these other basic needs being unmet. We examined the impact of supportive housing and case management on health care utilization among homeless individuals who are hospitalized frequently. METHODS: A social worker (S.S.) at John Stroger Hospital of Cook County identified subjects who were 18 years or older, hospitalized at least three times in the last 12 months at a Cook County Bureau of Health Services hospital, and met the Housing and Urban Development definition of being chronically homeless. The intervention consisted of case management including referral to interim housing and facilitated access to permanent housing. Baseline demographic data were collected through subject self-report, and investigators used Cook County Bureau administrative databases to collect information about hospitalizations, days in the hospital, emergency room (ER) visits, and clinic visits for each individual 12 months before and after enrollment. Time spent in permanent housing during the next 12 months was also recorded. Wilcoxon Signed Rank test was used to compare these measures 12 months before and after enrollment for 1) all enrolled 2) those enrolled who achieved permanent housing 3) those enrolled who did not achieve permanent housing. RESULTS: Investigators enrolled 34 individuals, and 21 achieved permanent housing. Nineteen achieved permanent housing for greater than 6 of the 12 months after enrollment. The average age of enrollees was 47.6 years, and 71% (n=24) were men. Among all individuals enrolled, average number of hospitalizations decreased from 3.9 to 1.3 after enrollment ($p=<0.001$), and mean days in the hospital decreased from 18.0 to 6.8 ($p=<0.001$). Mean number of ER visits decreased from4.3 to 2.6 but was not statistically-significant. Those who achieved permanent housing had significantly lower mean hospitalizations (3.8 to1.2, $p=<0.001$) and hospital days (18.3 to 8.6, $p=0.002$). However, even those individuals who did not achieve permanent housing

had lower rates of hospitalization (4.0 to 1.4, p=0.004) and lower mean hospital days (17.6 to 3.8, p=0.003) after enrollment in the program. In those who achieved permanent housing for greater than 6 months, case management and supportive housing is also associated with significantly lower mean number of ED visits (3.5 to 1.4, p=0.022). CONCLUSION: Among homeless individuals who are frequent users of hospitals, supportive housing and case management is associated with significantly lower rates of hospitalization and days in the hospital in the twelve months after enrollment compared to the twelve months before enrollment.

ELECTRONIC HEALTH RECORD IDENTIFICATION OF PRE-DIABETES AND AN ASSESSMENT OF UNMET COUNSELING NEEDS Laura Zimmermann 1; Jason Thompson 2; Stephen Persell3. 1 ; 2Division of General Internal Medicine, Feinberg School of Medicine, Northwestern University, Chicago, Illinois ; 3Division of General Internal Medicine, Feinberg School of Medicine, Northwestern University, Evanston, Illinois. (Tracking ID # 10937)

BACKGROUND: Over 57 million people in the United States have pre-diabetes, and 70% will progress to diabetes mellitus (DM) type 2. In

2002, two large clinical trials demonstrated that lifestyle modification consisting of diet, exercise, and sustained weight loss can reduce the incidence of DM in pre-diabetic, at-risk patients by approximately 60%. The Diabetes Prevention Program (DPP) went on to demonstrate a 34% reduction in DM incidence at ten years. However, recent National Health and Nutrition Survey (NHANES) data suggest that these practices have not been widely encouraged by physicians and that pre-diabetes often goes unrecognized.

Frequently, serum glucose measurements become part of the health record because serum glucose is included in popular laboratory bundles(i.e. basic metabolic panel, basic chemistry panel, etc.) that providers order to diagnose or evaluate conditions other than abnormal glucose metabolism. However, patients and providers are often not aware of these data and may not use these data to initiate preventive counseling for pre-diabetic patients. Electronic health record (EHR) -generated clinician reminders can keep appropriate preventive care from slipping through the cracks during a busy primary care visit, and have been shown to increase rates of preventive care.

We explored whether electronic health record (EHR) query based on glucose measurements can identify pre-diabetic patients eligible for lifestyle intervention, and we estimated rates of pre-diabetic lifestyle modification counseling.

METHODS: Subjects included men and women >18 years of age who attended at least three office visits in a large, urban, academic primary care practice in Chicago. Electronic search identified patients with plasma glucose levels of 100 to 199 mg/dl between June 1st, 2007, and June 1st, 2009, excluding those with diabetes or diabetic medications/ supplies documented as coded, searchable data in problem, diagnosis, or medication lists. This glucose range was chosen based on the most widely accepted definition of pre-diabetes: the presence of impaired fasting glucose (IFG) and/or the presence of impaired glucose tolerance (IGT). IFG is defined as fasting serum glucose levels of 100 to 125 mg/dl, and IGT is defined as serum glucose levels of 140 to 199 mg/dl two hours after an oral glucose load of 75 grams. From these 5,366 patients,100 randomly-selected subjects underwent classification into provisional categories based on all available EHR documentation on fasting state and concurrent fasting lipid panels: likely pre-diabetes, likely diabetes, abnormal glucose metabolism in the setting of acute illness, or possible normal glucose metabolism. In those likely to have pre-diabetes, investigators reviewed phone and office encounters 6 months before and after each glucose measurement to identify documented lifestyle modification counseling. We compared characteristics of subjects who did and did not receive lifestyle modification counseling using the two-tailed students t-test for normally-distributed continuous variables, Wilcoxon Rank Sum test for non-normally-distributed continuous variables, and the Fisher exact test for categorical variables.

RESULTS: The initial electronic query identified 5,366 non-diabetic patients who had attended the clinic over two years with glucose measurements in the range of 100199 mg/dl. Eighty-three percent had a glucose level of

100 to 125 mg/dl. Of the 100 randomly-selected patients (from the 5,366) for whom manual chart review was undertaken, 58% (95% CI 48 to 68%) of subjects met criteria for likely pre-diabetes. Fourteen percent were categorized as likely having diabetes, 21% had hyperglycemia in the setting of acute illness or corticosteroid use, and 7% had glucose measurements possibly reflecting normal post-prandial glucose levels. Four of 14 categorized as likely to have diabetes had no documentation of the diagnosis or a diabetes-related prescription recorded in the free text portion of the EHR, implying that these individuals had undiagnosed diabetes. Counseling was documented in 30.5% (95% CI 21 to 44%) of subjects likely to have pre-diabetes. Twenty-six lifestyle counseling events were

identified, comprising 24% of opportunities (95% CI 17 to 33%) in the 58 pre-diabetic individuals. We noted only one instance of documentation of a specific Diabetes Prevention Program recommendation, which appeared in a phone note and included the recommendation of weight loss of 7% of body mass. The difference in mean baseline BMI was clinically and statically significant when comparing those counseled to those not counseled (34.1 versus 29.9, p=0.037). Otherwise, there were no statistically- or clinically-significant differences between the two groups in terms of demographics (age, sex), co-morbidities (hypertension, dyslipidemia, coronary heart disease, congestive heart failure, cerebrovascular accident, transient ischemic attack), or clinical characteristics (glucose, creatinine, blood pressure, lipid levels). CONCLUSION: EHR query using a glucose measurement criterion can identify pre-diabetic individuals and those who require further evaluation of glucose metabolism, including subjects with undiagnosed diabetes. Our findings support the need to address glucose measurements of 100 to 199 mg/dl on a systemic or organizational level, potentially with physician reminders. Future research should investigate EHR-based, population-level interventions to facilitate pre-diabetes recognition and intervention, leading to improved quality of care.

POORER CLOCK DRAW TEST SCORES ARE ASSOCIATED WITH GREATER FUNCTIONAL IMPAIRMENT IN PERIPHERAL ARTERIAL DISEASE: THE WALKING AND LEG CIRCULATION STUDY II Laura Zimmermann 1; Mary McDermott2. 1Institute for Healthcare Studies, Feinberg School of Medicine, Northwestern University, Chicago, Illinois ;
2Division of General Internal Medicine, Feinberg School of Medicine, Northwestern University, Chicago, Illinois. (Tracking ID # 10938)

BACKGROUND: Men and women with lower extremity peripheral arterial disease (PAD) have greater functional impairment than those without PAD. Men and women with PAD have slower walking speed, poorer walking endurance, and lower physical activity levels compared to those without PAD. Impaired walking performance in PAD is not fully explained by the degree of lower extremity arterial obstruction. Thus, mechanisms for functional impairment in PAD are not fully understood.

Cognitive impairment is a major risk factor for decreased functional performance in the aging population and is more prevalent in those with PAD compared to those without cardiovascular disease. Individuals with PAD perform worse on multiple cognitive function tests compared to ageand education-matched controls without PAD. However, to our knowledge, no published studies have established an association between subtle cognitive disturbance and functional performance in individuals with PAD. This cross-sectional study determined whether cognitive impairment, assessed by the clock draw test (CDT) is associated with poorer functional performance among older, dementia-free individuals with PAD, independent of severity of arterial obstruction and potential confounders. METHODS: Participants were men and women age 60 and older with Mini Mental Status Examination scores 24 with PAD (n=339) and without PAD (n=234). Subjects were recruited from two urban vascular testing laboratories and a primary care clinic. Functional performance measurements included the 6-minute walk test, 4-meter walking velocity at usual and fastest pace, the Short Physical Performance Battery (SPPB), and accelerometer-measured physical activity at home. CDTs were scored using the Shulman method, which assigns points based on components of the clock and ranges from a score of 0 to 5, 5 being the

best score. Results adjust for age, sex, race, education, ABI, comorbidities, and other confounders. Clinical characteristics and associations between CDT scores and clinical characteristics were compared between PAD and non-PAD subjects using general linear models for continuous variables and chi-square tests for categorical variables. Analysis of covariance was used to analyze the relationship between CDT and functional performance measures after adjustment for demographics, comorbidities.
RESULTS: Clock draw test (CDT) scores were categorized using as follows: Category 1: CDT score 02, Category 2: CDT score 3, Category 3: CDT score 45. In unadjusted analyses of PAD participants, lower CDT scores were associated with slower usual- and fast-paced walking velocity, lower SPPB score, and lower levels of physical activity in those with PAD (p-trend=0.005, 0.003, 0.011, 0.005, respectively). After adjustment for age, sex, race, education level, ABI, cardiovascular disease, cancer, and pulmonary disease, lower CDT scores were associated with slower usual-paced walking velocity (Category 1: 0.78 meters/second; Category 2: 0.83 meters/second; Category 3: 0.86 meters/second; p-trend=0.024) and lower physical activity (Category 1: 420 activity units; Category 2: 677 activity units; Category 3: 701 activity units; p-trend=0.045) among PAD subjects.

In unadjusted analyses of participants without PAD, lower CDT scores were associated with slower normal and fast-paced walking velocity (p-trend=<0.001, <0.001) and a poorer SPPB score (p-trend=0.001). After adjustment for age, sex, race, education level, ABI, cardiovascular disease, cancer, and pulmonary disease among participants without PAD, lower CDT scores continued to be associated with slower usual-paced walking velocity (Category 1: 0.79 meters/second; Category 2: 0.95 meters/second; Category 3: 0.98 meters/second; p-trend=0.025), slower fast- paced walking velocity (Category 1: 1.17 meters/second; Category 2: 1.28 meters/second; Category 3: 1.33 meters/second; p-trend=0.044), and poorer SPPB scores (Category 1: 8.06 meters/second; Category 2: 10.29 meters/second; Category 3: 10.49 meters/second; p-trend=0.036).
CONCLUSION: Cognitive impairment is associated with poorer functional performance, independent of ABI, in older, non-demented individuals with PAD. Further prospective study is needed to determine the mechanisms of the association between CDT scores and functional performance in PAD participants and whether those mechanisms are unique to PAD participants compared to the general population. Longitudinal data are necessary to determine whether baseline CDT score or decline in CDT score predict decline in functional performance, institutionalization, or mortality in individuals with PAD
UNDERESTIMATION OF CALORIES PURCHASED AT FAST-FOOD RESTAURANTS-WHO AND HOW MUCH? Jason P Block 1; Suzanne Condon 2; Ken Kleinman 1; Sheryl Rifas-Shiman 1; Matthew W Gillman1. 1Harvard Medical School/Harvard Pilgrim Health Care, Boston, Massachusetts ; 2Massachusetts Department of Public Health, Boston, Massachusetts. (Tracking ID # 10939)
BACKGROUND: Obesity results from overconsumption of energy in relation to energy expenditure. Adults may over-consume because they are unaware of the calorie content of foods they buy. When presented with restaurant menus in experimental settings, adults underestimate the calorie content of meals they would choose, but no real-world evaluations exist of how well adults estimate the calories of the food they purchase. The purpose of this study was to quantify the difference between actual and reported calorie content of food purchased for dinner at fast-food restaurants in New England and to assess the correlates of underestimation.
METHODS: We interviewed adults 18+ years of age at fast-food restaurants during the baseline phase of a study to evaluate a coming federal regulation that will require chain restaurants across the US to post calories on their menus. We randomly selected 3 McDonalds, 3 Burger Kings, 2 Subways, 1 Wendys, and 1 KFC in each of Boston and Springfield, MA, Providence, RI, and Hartford, CT, for a total of 40

restaurants. We visited each restaurant three times from April to August 2010 between 5:15 to 7:30 pm, for 120

total restaurant visits. We attempted to approach all adults sequentially as they exited the restaurant. In exchange for a $2 incentive, we conducted a brief interviewer-administered survey to collect demographics, height and weight, food choices, and whether the participant saw and used nutritional information available in the restaurant. As part of the survey, we also asked each participant to estimate the calorie content of his or her dinner. To calculate the actual calorie content of food purchased, we used the participants receipt and nutritional information from restaurant websites. Using multivariable logistic regression accounting for clustering of respondents by chain, we examined correlates of large-scale underestimation (reported minus actual calories 500).
RESULTS: We interviewed 915 participants (7.6 respondents per restaurant), representing 36% of adults we approached. 59% of respondents were male, 38% were White, 33% were Black, and 20% Hispanic; 42% were 1829 years old, 31% were 3049 years, and 27% were 50 years old. 556 subjects (65%) were overweight or obese. The mean actual calorie content of meals was 836 calories (SD 425), and the mean underestimation was 135 calories (SD 753; IQ range 530 underestimate to 100 overestimate). 33% purchased 1000 calories, and 27% underestimated by 500 calories. The most important factors in food choice were taste (79% said taste mattered a lot), convenience (54%), price (32%), and calorie content (26%). 210 (23%) of participants reported seeing nutritional information in the restaurant, but only 38 (19%) of them used that information to inform their food choices. In multivariable models adjusted for age, race/ethnicity, BMI category, and sex, subjects purchasing 1000 calories were much more likely to underestimate calorie content by 500 calories (OR 10.43 [95% CI 7.13-15.24]). Noticing calorie information in the restaurant (OR 1.19 [95% CI0.74-1.92]) was not associated with underestimation. The importance of taste, convenience, price, and calorie content also were unrelated. Compared with Whites, Asians (OR 3.35 [95% CI 1.26-8.90]), Blacks (OR2.54 [95% CI 1.59-4.06]), and Hispanics (OR 3.60 [95% CI 2.08-6.24]) were more likely to underestimate. 18-29-year-olds v. 50-year-olds (OR 0.57 [95% CI 0.34-0.94]) were less likely to underestimate, and BMI and sex were unrelated. Correlates of purchasing a 1000-calorie meal were underestimation of calorie content by 500 calories and age 18 to 29 years old v. 50 years old. The importance of calorie content (mattered a lot v. not at all) predicted a lower odds of ordering a 1000-calorie meal. CONCLUSION: One-third of adults visiting fast-food restaurants in New England purchased 1000 calories for dinner, and 27% underestimated the meals calorie content by 500 calories. Purchasing 1000 calories strongly predicted underestimating calorie content of meals by 500 calories. Minorities were more likely to underestimate calorie content, and 18-to-30-year olds were less likely. Collection of similar data after the federal menu labeling regulation goes into effect will help determine the impact of the regulation on these patterns of knowledge and consumption. The strong association of large-calorie meal purchases and underestimation of calorie content holds promise that menu labeling could make calories more salient.
MAPPING NEGLECTED TERRAIN: HOW FRONT-LINE NURSING HOME STAFF ASSESS AND COMMUNICATE ABOUT CHANGE IN CONDITION Karen Glasser Scandrett 1; Mary Ann Anichini 2; Celia Berdes 3; Kenneth Boockvar 4; Debra Saliba 5; Linda Emanuel 3; Stephanie Taylor5. 1Northwestern University, Chicago, Illinois ; 2Presbyterian Homes, Lake Forest, Illinois ; Buehler Center on Aging, Chicago, Illinois ; 4The Mount Sinai Medical Center, New York City, New York ; 5RAND Corporation, Santa Monica, California . (Tracking ID # 10940)
BACKGROUND: Nursing home residents are dependent on nursing aides (NAs) for basic daily care, socialization and other quality of life activities, and the early detection of clinical changes. Contact with registered nurses is limited, and physician visits may be infrequent. Although NAs may detect important changes in a resident up to five days before they become clinically significant, and despite the availability of tools to help staff report and document changes, residents regularly experience unplanned discharges for potentially preventable clinical problems. Methods from safety sciences may help to implement better communication and management practices among nursing home staff, but these methods are not utilized by many nursing homes, and gaps in staff education and training exist. As part of a larger curriculum development

project to train nursing home staff members in patient safety, we conducted focus groups to understand how staff detect clinical changes and communicate about it with other providers. We used a patient safety framework to identify the organizational structures and processes needed for effective clinical care and team communication.
METHODS: Four focus groups were conducted by a trained facilitator at a single, non-profit suburban facility; two groups were comprised of NAs and two of licensed staff members, with day and evening shifts divided. An interview guide addressed four training-responsive conceptual areas derived from prior literature review and expert panel consensus: 1) How staff learn about their residents typical health patterns; 2) How staff watch for clinical changes (who watches and what is noted); 3) What clinical changes are perceived to be significant and must be reported; and 4) How staff communicate about changes in their resident. Within each training concept, questions were also asked to ascertain barriers to or facilitators of performing each task. Transcribed interviews were analyzed for themes in an iterative process by multidisciplinary team members.
RESULTS: A total of 12 staff participated in the four groups. They reported using multiple sources of information to develop their understanding of residents baseline function, and to detect subtle clinical changes. They regarded all clinical changes as potentially significant, and described multiple methods for communication about them with various team members. Communication between CNA and nurse was reported to be not consistent or reliable. Physician response resulting from communication between nurse and physician depended on physician familiarity with the resident and was not perceived as effective in achieving desired results.
CONCLUSION: Front-line nursing home workers self-report skill in detecting subtle clinical change in their residents, but are less confident in assessing the significance of those changes. Staff members developed some creative approaches to communicate within their discipline, but interdisciplinary communication is not a systematized routine and the desired clinical outcome is not always achieved. Skills and tools for structured clinical assessment, effective interdisciplinary communication, and exposure to systematic approaches to implement improvements are important topics for further training. Patient safety science offers an important framework to shape efforts for quality improvement in nursing facilities.
A RESIDENT-RUNCOMMUNITYHEALTHFAIR:POSSIBLEIMPLICATIONS FOR IMPROVED HEALTHCARE COMMUNICATION Douglas P. Olson 1;
Barry G. Fields 1; Stephen J. Huot 1; Donna M. Windish1. 1Yale Primary Care Residency Program, New Haven, Connecticut. (Tracking ID # 10942)
BACKGROUND: Health fairs are a common public health promotion activity, and one way internal medicine residency programs can increase

community involvement. While education and screening are major goals, the motivation and expectations of the attendees may inform a more rational health fair design, and also provide insight into patient-physician communication.
METHODS: All English and Spanish speaking participants at the Yale Primary Care fall 2010 health fair in Waterbury, CT were asked to participate anonymously in a survey to collect demographic data and basic information about their medical history. These data were matched with health screening results that included measurements of blood pressure, BMI, and glucose. The survey was approved by the Yale University IRB.
RESULTS: 228 attendees participated in the survey; 176 (75%) were female; the average age was 54 years [range 21 to 84]; 164 (72%) spoke English; 30% had less than a high school education, while 6% had a college education or greater; 73% had a primary care provider; and 80% had insurance, including state Medicaid. Based on BMI results, 26% were overweight, 30% were obese and 23% were morbidly obese. On fingerstick measurement, 30% had impaired fasting glucose, 22% had a glucose 126199 mg/dL, and 5% had glucose 200 mg/dL. 31% of blood pressure readings met a diagnosis for essential hypertension (140/90 mmHg). Overall, 41% had visited the emergency room (ER) for care at least once in the past year (range of ER visits was 1 to

18) and 28% (or 68% of those who visited the ER) had been admitted to the hospital in the prior year. Despite these numbers, 80% of participants rated their health as good or better, 18% as fair and 2% as poor.
CONCLUSION: The community served by this health fair was a largely English-speaking, middle-aged, overweight female population with a low level of formal education. The Spanish speaking population (30%) is slightly higher than the Latino population of Waterbury (24.1%). Despite 4 out of 5 attendees having insurance, and 73% having a primary care provider, 2 out of 5 had visited the ER for care in the past year, and many of them were admitted to the hospital. These data underscore the significant and complex medical problems faced by underserved populations and reflect the national trend of increased ER visits for care, even among those with access to primary care. Additionally, as many people had routine primary care providers, this survey demonstrates that most attendees came for additional health information and education and not for a diagnostic or therapeutic intervention, suggesting that doctor-patient communication for this population could be augmented which may lead to decreased ER visits as well. Further research into these areas is needed.
THE DISCLOSURE GAP: PATIENT AND PROVIDER PERSPECTIVE ON THE QUALITY OF ACTUAL DISCLOSURES Thomas H Gallagher 1;
Douglas Brock 1; Mary Eichler 2; Alan Lembitz 3; David M Studdert 3; Jeff Varnell 3; Dennis J Boyle4.
1University of Washington, Seattle, Washington ; 2COPIC, Denver, Colorado ; 3University of Melbourne, Melbourne, N/A ; 4University of Colorado Health Science Center, Denver, Colorado . (Tracking ID # 10943)
BACKGROUND: Disclosing unanticipated outcomes to patients is an expectation of accreditation standards and national quality organizations. Preliminary studies suggest that a sizable gap exists between these expectations and current practice. Yet few studies have measured the quality of actual disclosures.
METHODS: We developed and validated a brief survey to assess patients and physicians ratings of the quality of actual disclosures. The surveys were administered to patients and physicians who were participating in the 3Rs program of COPIC Insurance, a program to promote disclosure of certain unanticipated outcomes and to reimburse patients for out-of-pocket expenses and lost time. Patients and
physicians rated the overall quality of the disclosure. Patients were also asked whether specific disclosure elements recommended by consensus guidelines were present in the discussion, and how likely they were to return to this physician if they needed similar care in the future. The surveys were distributed to 908 patients and 936 physicians between 20072009 after management of the event in the 3Rs program had been concluded.
RESULTS: Surveys were returned by 817 physicians (87%) and 514 patients (57%). Physicians and patients did not agree on the severity of the event in question. 33% of patients considered the event to be extremely serious (I might have died), compared with 8% of physicians (P<.0001). When asked to rate the quality of the disclosure on a scale from 0 (extremely dissatisfied) to 10 (extremely satisfied), physicians were much more satisfied with the quality of the disclosure (mean 8.1) than were the patients (mean 6.2, P<.001). 41% of patients rated the quality of the disclosure as a 5 or less. Regarding patient assessment of specific disclosure elements, physicians scored highest on explaining the event in terms the patient could understand (68% agreed), providing a sincere apology to the patient (65% agreed), and being truthful when explaining the event (64%). In contrast, only 37% of patients agreed that the physician assured them that steps would be taken to prevent similar events from happening again. Ten items from the patient survey were combined into a Patient Satisfaction Scale (Chronbach alpha=.96). Lower Patient Satisfaction scores were associated with higher patient perception of the severity of the event (Spearman correlation=.15, P=.002) and with a lower likelihood of returning to that physician for future care (Spearman correlation=.78, P<.001).
CONCLUSION: Measuring patient and physician ratings of actual disclosures is feasible, and reveals substantial shortcomings. Routinely measuring disclosure quality could help organizations target efforts to improve these challenging conversations.
PUBLIC REPORTING FOR PERCUTANEOUS CORONARY INTERVENTIONS IN NEW YORK STATE Lena

M. Chen 1; Endel John Orav 2; Arnold M. Epstein3. 1Ann Arbor VA Medical Center, and Division of General Medicine, Department of Internal Medicine, University of Michigan, Ann Arbor, Michigan ; 2Division of General Internal Medicine, Brigham and Womens Hospital and Harvard Medical School, Boston, Massachusetts ; 3Dept. of Health Policy and Management, Harvard School of Public Health; Division of General Medicine, Harvard Medical School and Brigham &Womens Hospital, Boston, Massachusetts. (Tracking ID # 10950)
BACKGROUND: Prior studies of public reporting on risk-adjusted mortality for coronary artery bypass grafting (CABG) have found that public reports have strong predictive validity and likely encourage poor quality surgeons to leave practice. However, except for CABG surgery, there are few data on the predictive accuracy of public reports or their impact on providers practice. We used data from New York State on percutaneous coronary interventions (PCIs) to address three questions:1) what is the predictive accuracy of public reports for PCIs, 2) what is their impact on market share, and 3) is report performance associated with decisions to leave practice?
METHODS: We examined quality performance by hospitals (and cardiologists), as measured by publicly reported risk-adjusted mortality rates (RAMRs) for non-emergent PCIs performed in New York State between 1998 and 2007. For hospitals (and cardiologists) in each performance quartile, we estimated: 1) the average risk-adjusted mortality rate after report publication, 2) the change in market share from pre-release to post-release year, and 3) the proportion of physicians leaving practice in the post-release year.

RESULTS: Between 1998 and 2007, the New York State public reports included data on 351 cardiologists who performed non-emergent PCIs at 49 hospitals. We found that report cards had poor predictive ability for hospitals. For example, in 20022004, average hospital RAMRs increased monotonically from best to worst performance quartiles (RAMRS of 0.21, 0.27, 0.36, and 0.50, p-value <0.001). In the year after the report was published, hospitals in the worst performance quartile in 20022004 still had the highest RAMR of any quartile but the association was not significant and none of the trends were monotonic (RAMRs from best to worst quartile: 0.56, 0.57, 0.59, 0.77, p-value=0.30). We found that public reports for cardiologists were inconsistent in their ability to predict future performance. For example, between 2005 and 2007, patients who picked a cardiologists from the worst performance quartile (based on the 20012003 report), had a higher chance of dying than those who picked a cardiologist from one of the other three quartiles (RAMRs of 0.61, 0.56, 0.52, 0.83; p=0.005). However, performance was similar across the top three quartiles, and none of the other years we examined had statistically significant results. Performance ranking was not associated with a change in market share for hospitals or for physicians (all p>0.05). There was no association between report performance, and decisions to stop practicing in New York after report publication (4% in top and bottom quartiles; p>0.05).
CONCLUSION: We found that the New York State reporting system for PCIs has poor predictive accuracy for hospitals, and inconsistent predictive accuracy for cardiologists. We found no evidence that consumers or payers are using the public reports to drive market share, or that cardiologists who perform poorly are more likely to leave practice after report release. The utility of public reporting may differ substantially for different procedures.
PUBLIC OPINIONS ABOUT PAYING PEOPLE TO TAKE THEIR MEDICINES James D. Park 1; Jessica Metlay 2; Jeremy M Asch 3; David A Asch1. 1University of Pennsylvania, Philadelphia, Pennsylvania ; 2Vassar College, Poughkeepsie, New York ; 3Brandeis University, Waltham, Massachusetts. (Tracking ID # 10951)
BACKGROUND: There is considerable interest in using financial incentives to improve peoples health. In fact, financial incentives are of increasing national interest, as legislative elements are embedded in the Affordable Care Act. However, paying people to improve their health touches upon strongly held views about personal

responsibility. As various stakeholders consider financial incentives for improving health, public opinions regarding social and ethical issues related to their use have yet to be defined. This study aims to evaluate public opinions about the use of financial incentives to improve health.
METHODS: The New York Times article, For Forgetful, Cash Helps the Medicine Go Down by Pam Belluck, highlighted a study using financial incentives to improve Warfarin adherence. The article, published on June 13, 2010, resulted in 217 reader comments posted by June 14th. A second article, Should People Be Paid to Stay Healthy, was published on June 14, 2010 and contained five commentaries from experts in bioethics and health policy. This article elicited 177 reader comments from June 15 to June 28, 2010. The content of readers comments was systematically analyzed. Three reviewers read comments from both articles to identify common themes. Comments were randomly divided into a training set and an evaluation set. Two reviewers worked together to assign themes to each of the comments in the training set. Comments could be assigned multiple themes or none at all. Through that process, the
original set of themes was modified to a more consistent set to which all reviewers agreed. Two reviewers worked independently to code the comments in the evaluation set. To test for inter-rater reliability, kappa scores were calculated for each theme. Differences in coding were adjudicated between the two reviewers (using the third reviewer for disagreements) and the coding of all comments was combined into a single set for analysis.
RESULTS: Participant information was unavailable. General data about the online readership was obtained: 48.9% are women; 62.8% are between the ages of 2554; 48.6% earn an income of $75,000 or more;84.3% have some college education.
Average number of themes assigned to a comment was 1.5 and ranged between 06. Kappa scores ranged between 0.45-0.75 with a mean of0.64, indicating generally good agreement.
Themes, percent of comments representing the theme, &select exemplarsAlternative IncentivesGood health should be the ultimate incentive (10%)
Penalties should be used as an incentive (20%)
Ethical &Social IssuesFinancial incentives reward people for irresponsibility (21%) Were going to reward people for being lazy and stupid.
Financial incentives indirectly penalize people with good health habits (10%) Responsible members of our society must constantly pay the price for the stupidity of others.
Financial incentives will ruin people and society (6%) With each act that we as a society take to mitigate personal responsibility, we create ever more inept and dysfunctional fellow citizens.
People will game the system to win the financial incentive (3%) Financial incentives are paternalistic (4%)
Negative Public PerceptionsPeople make moralistic judgments or negative assumptions about individuals who use financial incentives.(11%)
People think the government is involved in financial incentives.(11%) People distrust the health profession and the services they provide. (12%)
The idea of paying people to take medications is absurd, outrageous, etc. (25%)
Positive Public PerceptionPeople support the use of financial incentives (13%) Less expensive to pay them to take the meds than to watch them fall apart. CONCLUSION: The comments revealed largely negative perceptions of financial incentives that may limit the public acceptability and uptake of this approach. In addition, the comments conveyed an appeal for greater personal responsibility for individual health. Despite the negative perceptions, there was measurable but minority support for the use of financial incentives, particularly from individuals who recognized good health practices may avert higher healthcare costs for chronic conditions later in life.
PRE-CLINICAL MEDICAL STUDENTS KNOWLEDGE AND ATTITUDES IN CARING FOR LESBIAN, GAY, BISEXUAL AND TRANSGENDER PATIENTS Nicole Rosendale 1; Benjamin Cox 2; Allison Avery 1; ColleenC. Gillespie 3; Adina Kalet 4; Richard Greene1. 1NYU School of Medicine, New York, New York ; 2New York

University School of Medicine, Brooklyn, New York ; 3NYU School of Medicine, Brooklyn, New York ; 4NYU School of Medicine, NY, New York . (Tracking ID # 10952)

BACKGROUND: While Americans have grown much more accepting of lesbian, gay, bisexual and transgender people, little research has investigated pre-clinical medical students knowledge and attitudes in

caring for lesbian, gay, bisexual and transgender (LGBT) patients. This study provides results of a survey of such knowledge and attitudes in 1st and 2nd year medical students. The survey will ultimately serve as a pre-test for evaluating the impact of an LGBT health curriculum. A similar study conducted in the same medical school in 2006 also allows for identification of secular trends.

METHODS: In December 2010, first and second year medical students at NYU School of Medicine were sent an email requesting their participation in a 39-question survey designed to assess their knowledge, attitudes and confidence in caring for LGBT patients. Knowledge was assessed via 20 multiple choice and true/false questions focusing on five major content areas: epidemiology of health issues in LGBT populations, anatomical and physiological aspects of transgender individuals, equity/access to health care, medical practice with LGBT patients (e.g., how to ask about sexual behavior; prevalence with which gay men disclose sexual orientation to their physicians), and sociocultural issues. Attitudes were assessed on a 5-point agreement scale and are grouped into four (conceptual and empirically supported via factor analysis) categories: attitudes toward LGBT patients, attitudes about comfort/confidence in treating LGBT patients, attitudes about the need to know about sexual orientation and behavior to effectively treat, and views of whether most primary care physicians can effectively treat LGBT patients. Students were also asked about their connections with and experience in treating LGBT individuals. Repeated measures ANOVAs with Bonferroni-corrected multiple comparisons were used to compare content areas within the overall knowledge scores and attitude items.

RESULTS: A total of 155 of 330 students responded (47% response rate). Students, on average, got 59% of items correct on the 20-question knowledge assessment (SD=13%). Students who identified as LGBT or had clinical experience with LGBT patients had significantly higher knowledge scores. Knowledge was lowest in the medical practice (mean 34% correct, SD 38%) and epidemiology (37% correct, SD 16%) and highest in the transgender (84% correct, SD 19%) and sociocultural (74% correct, SD 32%) areas. Students generally held positive attitudes toward LGBT patients (mean endorsement of positive statements about LGBT patients=4.3, SD .6) but were slightly less comfortable/confident in treating LGBT patients (mean=3.6, SD .9) and reported slightly less positive attitudes toward needing to know (mean=3.7, SD .6). Most students did not strongly endorse that most primary care physicians can effectively treat LGBT patients (mean=2.3, SD .8). Knowledge and attitudes were fairly similar to those found for 3 rd and 4th year medical students in 2006.

CONCLUSION: Knowledge of LGBT health concerns, as measured in our survey, suggests the need for more education for preclinical students, particularly since identification with the LGBT community and clinical exposure to LGBT patients is associated with higher scores and more positive attitudes. Students in our sample need to learn more about clinical practice with and the epidemiology of health issues with LGBT patients and some students report discomfort and lack of confidence in conducting physical exams on and discussing sexual behavior with LGBT patients.

CONFINED TO IGNORANCE: THE ABSENCE OF PRISONERS FROM NATIONAL HEALTH DATA Brie Williams 1; Cyrus Ahalt 1; Ingrid A Binswanger 2; Michael Steinman1. 1University of California, San Francisco and SFVAMC, San Francisco, California; 2University of Colorado, Denver, Aurora, Colorado. (Tracking ID # 10954)

BACKGROUND: As of 2008, 1 in 31 Americans was incarcerated, on parole or probation, and 1 in 15 was expected to spend time in prison

during his or her lifetime. Although studies show that persons currently or previously incarcerated are in worse health and generate higher health care costs than the general public, such studies are small, infrequently

conducted, and incorporate limited measures of health (e.g. self-report of selected medical conditions within larger criminal justice questionnaires). Our goal was to analyze leading publically available national health datasets for questions that could be used to assess the health of persons with a current or prior history of incarceration.
METHODS: We analyzed all 48 datasets from the Society of General Internal Medicine (SGIM) Dataset Compendium, a resource providing links to major national datasets for generalist researchers. Five were not publically available, 7 did not include patient-level health data, and 4 were not relevant to US prisoners and were excluded, resulting in 32 datasets. For each dataset, we examined all publicly available documentation (questionnaires, codebooks, and results summaries) for the terms: Jail, Prison, Incarceration, Crime, Criminal, Convict, Victim, Police, Correctional, Corrections. We then determined each datasets stated focus (health care costs, health disparities, older adults, youth, health risk factors) and sample construction (longitudinal, cross-sectional). In a secondary analysis, we contacted all 12 longitudinal study investigators to determine whether subjects who became incarcerated during the study were dropped and/or reenrolled after release; 3 studies did not respond to 2 emails and 1 phone call and were therefore not considered for subsequent analyses.
RESULTS: Of the 32 datasets, 20 were cross-sectional and 12 were longitudinal. Datasets focused on health disparities (9), health care costs (7), older adults (6), youth (5), and/or health risk factors (11). None was designed to investigate the health of persons with a current or past history of incarceration. Subjects incarcerated at the studys outset were excluded in 25 datasets (78%); the remaining 7 may have included prisoners but did not code them as such (e.g. studies of all hospitalized patients in the US). Eight studies (25%; 4 cross-sectional, 4 longitudinal) included a question with one of our keywords. Of these, 4 (1 cross-sectional (USRDS) and 3 longitudinal (MIDUS, ADDHEALTH, CARDIA)) included a question that could be used to define a group with a history of incarceration. The others did not differentiate incarceration from other criminal justice problems (e.g. Question: Do you have legal problems, such as imprisonment, prosecution, lawsuits, or litigation?). The 4 datasets with a question about incarceration history were focused on health risk factors (3 - CARDIA, ADDHEALTH and USRDS), health disparities (3 - CARDIA, ADDHEALTH and MIDUS), and youth (1- ADDHEALTH). Notably, only 3 of 9 studies focused on health disparities and none of the studies focused on health care costs assessed incarceration. Our secondary analysis of longitudinal studies showed that only 2 of 9 both followed subjects through incarceration and generated a new code to indicate that they had been incarcerated (ADDHEALTH and CARDIA). The remaining studies either dropped those who became incarcerated (44%) or followed them but did not indicate they had been incarcerated (33%).
CONCLUSION: Large health-related datasets can provide accurate, unbiased, and relevant data to researchers, public health experts, clinicians and policy-makers. Of the 32 national health datasets reviewed, 1 cross-sectional and 3 longitudinal datasets could be used to investigate the health of persons who have been incarcerated. The association between incarceration and poorer health has been documented for the large and growing criminal justice population which is overrepresented by racial and ethnic minorities. A lack of relevant data, however, precludes more rigorous assessment of incarcerations impact on health disparities, risks for specific health outcomes, and health care

costs. In 2007, the Institute of Medicine issued new ethical guidelines for prisoner health research recognizing that access to research may be critical to improve the health of prisoners. Our findings suggest that a good place to start would be through the broader inclusion of incarceration-related questions in national health datasets.
INVITING PATIENTS TO READ THE DOCTORS NOTES: HOPES, FEARS, AND DISSONANCE Jan Walker 1; Suzanne G. Leveille 2; Long Ngo 1; Elisabeth Vodicka 3; Jonathan D. Darer 4; Joann G. Elmore 5; Henry J.

(Tracking ID # 10955)
BACKGROUND: As the public demands better care and greater transparency, providers increasingly offer patients online access to laboratory results and other parts of their electronic medical records through secure Internet portals. However, few clinicians routinely share encounter notes with their patients. OpenNotes, a yearlong research and demonstration project involving primary care physicians (PCPs) and their patients in Boston (BOS), Pennsylvania (PA), and Seattle (SEA), is inviting patients to review their doctors notes online. We hypothesized that patients would be generally positive in their attitudes toward open notes, although there might be differences based on demographic and health factors, and that PCPs would be generally less positive. Prior to providing access to notes, we surveyed eligible patients and doctors about their attitudes and expectations. METHODS: We conducted online surveys of patients and PCPs from the 3 participating primary care settings: an urban academic health center and associated community practices (BOS), a primarily rural integrated health system (PA), and a county hospital serving mainly indigent patients (SEA). Eligible patients and PCPs in BOS and PA had active
portal accounts; patients and PCPs in SEA used a portal made accessible for the OpenNotes project. Drawing on insights from focus groups and individual interviews, we developed surveys designed to solicit patients perceptions about potential benefits and risks related to reading their PCPs visit notes and included a set of parallel items in surveys of their PCPs. Survey invitations were sent to PCPs by email and to their patients through secure patient Internet portals. We calculated proportions of patients and PCPs agreeing or disagreeing with a series of benefit and risk statements. In addition, we evaluated patients perceptions of benefits and risks according to demographic and health characteristics.
RESULTS: 38,325 patients and 174 PCPs completed surveys. Patient response rates were 40% in BOS, 43% in PA, and 100% in SEA where all patients joining OpenNotes (n=273) completed surveys at enrollment. PCP response rates were 83% in BOS, 52% in PA, and 75% in SEA. Among patients, mean age was 52 years (SD 14, range 18103), with 63% female, 95% white, and 64% employed. 27% reported education up to high school (HS); 29% had some college; 17% graduated college; and 26% had post-college education. 16% reported fair/poor health.93% of patients wanted to look at their notes, and 94% thought open notes a good idea, compared to 55% of PCPs. Patients and doctors also differed on risks and benefits (see Table 1). Demographic and health characteristics accounted for few differences among patient perceptions of benefits and risks. However, 94% of those with HS education or less felt they would take better care of themselves, compared to 84% of those with the most education. Similarly, 84% of those with HS education or less felt that open notes would help them remember to take medications, compared to 64% of those with advanced education. Those rating their health fair/poor felt they were more likely than those with better health to take medications as prescribed (83% vs. 73%). We found no substantial differences in perceptions of risks according to patients characteristics. CONCLUSION: Overall, patients were remarkably positive about the prospect of reviewing their visit notes online and anticipated many benefits and few risks in doing so. The majority of PCPs were also positive about potential benefits, but they were strikingly more worried about risks. The implications of such open interchange are complex, and we look forward to the end of our year-long intervention when both patients and PCPs will report on their experiences with OpenNotes.

GENDER DISPARITIES IN LIPID-LOWERING THERAPY AMONG VETERANS WITH DIABETES Varsha G.

Vimalananda 1; Donald R. Miller 2; Madhuri Palnati 2; Cindy L. Christiansen 3; B. Graeme Fincke4. 1Boston University Medical Center, Boston, Massachusetts ; 2VA Center for Health Quality, Outcomes, and Economic Research, Bedford, Massachusetts ; 3Boston University School of Public Health, Boston, Massachusetts. (Tracking ID # 10956)

BACKGROUND: Women with diabetes are more likely than men to have a low-density lipoprotein cholesterol (LDL) above recommended levels. This is an important quality issue because 1) hyperlipidemia is a risk factor for cardiovascular disease, 2) hyperlipidemia may have a higher impact on cardiovascular outcomes in women compared to men with diabetes, and 3) treatment of hyperlipidemia with statins in diabetes is associated with a more than a 20% reduction in cardiovascular disease risk. The reasons for worse lipid control among women with diabetes are unclear, but may be due in part to differences in treatment patterns. We undertook this study to assess differences in lipid-lowering therapy between female and male veterans with diabetes and elevated LDL. METHODS: We conducted a cross-sectional study of veterans serviced by the Veterans Health Administration (VA) in 2006 who had both diabetes and hyperlipidemia and compared all females (N=22,475) to age- and facility-matched males (N=89,431). We compared proportions of patients with any VA prescription for lipid-lowering therapy in the year and, among those with elevated LDL (>100 mg/dl) and no prior treatment, we compared initiation of lipid-lowering therapy. Likelihood of treatment was estimated using multiple logistic regression with adjustment for race, VA eligibility, health care utilization, cardiovascular diseases, mental health conditions, and a comprehensive list of other co-morbidities. We also performed the analysis stratified by age. RESULTS: Women had higher LDL levels than men (11038 vs. 101 36 mg/dL) and fewer of them were receiving lipid-lowering therapy (80% vs. 84%). Women were less likely to receive therapy (adjusted odds ratio [95% confidence interval]: 0.79 [0.76-0.82]) or to be initiated on such therapy (37% vs. 42%, 0.84 [0.770.90]). Differences were greatest in the youngest women (<45 years old) for both any lipid-lowering therapy (61% vs. 75%, 0.53 [0.480.59]) and initiation of therapy (27% vs. 39%,0.56 [0.470.67]). Adjustment for potential confounders did not change the risk estimates.
CONCLUSION: Women veterans with diabetes and hyperlipidemia receive less aggressive lipid-lowering therapy than men, especially in younger age groups. This disparity is of concern, because early intervention to control hyperlipidemia can reduce the later burden of cardiovascular disease among diabetic women.

TASTE IS EVERYTHING: A QUALITATIVE STUDY OF BEVERAGE CONSUMPTION IN COLLEGES Jason P Block 1; Matthew Gillman 1; Stephanie Linakis 1; Roberta Goldman2. 1Harvard Medical School/ Harvard Pilgrim Health Care, Boston, Massachusetts ; 2Brown University School of Medicine, Providence, Rhode Island. (Tracking ID # 10957)

BACKGROUND: Young adults consume more sugary beverages than any other age group, leading to increased risk for weight gain. Limited data are available to explain the reasons for this high sugary beverage consumption or to provide insights into how behavioral interventions might reduce consumption. We conducted a qualitative study to examine these factors among college students.
METHODS: We conducted a total of 12 focus groups of freshman and sophomore students in 6 colleges located in Massachusetts and Louisiana, including 2 historically black colleges. Prior to each focus group, participants completed a brief survey about demographics and
factors that determine beverage choice. We asked a core set of questions at each group addressing students behaviors around the consumption of beverages, and their opinions about proposed interventions in colleges to reduce sugary beverage intake. Discussions were audio-recorded and professionally transcribed. We conducted a content analysis of the focus group transcripts using the principles of the immersion-crystallization method. This qualitative approach consists of the analysis team individually reviewing the transcripts and engaging in a series of group analysis discussions to identify dominant themes and preliminary interpretation of the data. Next, we used a group consensus procedure to create a code book and code definitions, and we subjected the transcripts to line-by-line coding. Analysis of resulting code reports facilitated further comparison

of data from each of the 12 transcripts and final interpretation of the findings.
RESULTS: 90 students participated in the 12 focus groups (mean 7.5 participants per group). Mean age was 19 years old; 63% were female; 55% were freshman; 50% were White; 47% were Black. In pre-focus group surveys, nearly all (93%) participants reported that taste was an important factor in determining beverage choice followed by price (58%) and calorie content (30%). In the focus group discussions, taste remained the most important reason for choosing a beverage. Students were often quite fixated on favorite sugary beverages: I want to drink my favorite drinks until the day that youre going to die and If theyre healthy or not Im going to drink it if Im thirsty. They considered changing from a favorite drink difficult: It takes . . . one of those [near] death experiences but something like really drastic to change. Price was important, and students sought value: You get a lot for that dollar and Only label I look at is the price label. Health and calorie content had limited contribution to beverage choices: When its not like an immediate negative effect . . . no matter how unhealthy . . . you tell people something is, I dont really think anyone is going to like take it to heart. Some students reported calorie content of food as an important determinant of their diet but rarely considered drinks as substantial contributors to overall calorie intake: Some people think about it when theyre doing their food, but drinks . . . [are] overlooked. The strongest themes emerging about the negative impact of sugary beverage consumption were the perceived dangers of the mysterious chemical content of dark sodas. Although Black and White students were mostly similar in their perspectives and behaviors, in the pre-focus group survey 60% of White v. 0% of Black students reported giving some consideration to the calorie content of beverages when choosing what to drink.
CONCLUSION: Among a diverse group of college students in two states, taste and price were the most important factors in choosing beverages with little thought given to health impact. The disconnect between consideration of calorie content of food v. beverages raises the possibility that educational interventions that present the caloric content of beverages in food currency may be beneficial.
IMPROVINGFOLLOW-UP OFABNORMALTEST RESULTS: EVALUATING THE IMPACT OF A MANDATORY NOTIFICATION Archana Laxmisan 1;
Dean Forrest Sittig 2; Donna Espadas 3; Kenneth Pietz 3; Hardeep Singh1. 1Baylor College of Medicine; Houston VA HSR&D Center of Excellence, Michael E. DeBakey Veterans Affairs Medical Center, Houston, Texas ; 2University of Texas Health Science Center, Houston, Texas ; 3Houston VA HSR&D Center of Excellence, Michael E. DeBakey Veterans Affairs Medical Center, Houston, Texas. (Tracking ID # 10958)
BACKGROUND: Concerns about timely follow-up of abnormal imaging and lab test results remain despite electronic notifications to providers. In the Veterans Health Administration (VA), there is a wide variability in

what notifications are delivered to the clinician due to individual preference and system-level mandates. On March 11, 2009, a change in the VA electronic health record (EHR) was implemented to require all pathology results (normal or abnormal) to be transmitted to ordering providers via EHR-based automated notifications that cannot be switched off by providers (mandatory alerts). We examined the impact of this intervention on follow-up of abnormal pathology results in the outpatient setting.
METHODS: We conducted retrospective chart reviews to evaluate preand post-intervention follow-up outcomes at two large VA facilities. We electronically extracted all pathology reports in a six-month time-frame before and after the date of intervention. From 16,738 pre-intervention and 17,305 post-intervention reports at two sites, we randomly selected 688 and 706 abnormal outpatient reports, respectively. Trained reviewers collected outcome data using a standardized pre-tested data collection instrument, on all possible acceptable follow-up actions for up to six months post alert transmission. Follow-up actions were defined as documentation of either 1) ordering or performance of an appropriate follow-up test or referral, 2) prescribing or changing treatment based on result,

3) patient notification of test result, 4) subsequent hospitalization where the result was addressed, or 5) other documentation of appropriate provider-recognition such as noting patient preference to decline or to seek follow-up elsewhere. Reviewers also categorized follow-up actions as direct or indirect, depending on whether they could clearly link the action directly to the report. For example, a direct action would be a letter communicating results to a patient, while an already scheduled consultation before the result was available would be an indirect action. Outcome measures included proportion of abnormal reports with lack of any follow-up within 6 months and median time to direct follow-up action pre-and post-intervention.
RESULTS: Post intervention, the proportion of reports without follow-up decreased significantly (9.8% vs.3.5% p<0.01). However, median time to direct follow-up action was unchanged pre and post intervention (8 days IQR 515 days vs. 8 days IQR 5-14 days; P=0.6)
CONCLUSION: Notification of abnormal pathology results is likely more effective at improving follow-up when made mandatory than when providers are allowed to customize receiving these results on their own. However, mandatory notification did not lead to fail-safe follow-up at six-months or prompt earlier follow-up actions by ordering providers. Thus, interventions other than making test result alerts mandatory in EHR are needed to ensure direct follow-up actions on patients abnormal pathology results in the outpatient setting. These interventions should be designed to address the several socio-technical factors that contribute to patient safety in a complex environment.
USING THE INDEX OF RELATIVE RURALITY (IRR) TO ESTIMATE DEGREE OF RURALITY AT THE SMALL-AREA LEVEL IN HEALTH SERVICES RESEARCH Sanae Inagami 1; Shasha Gao 2; Martine Shendge 2; Janice Probst 3; Hassan Karimi 4; Roslyn Stone 5; Mary Ann Sevick 6; Michael Fine2. 1 ; 2VA Pittsburgh Healthcare System, Pittsburgh, Pennsylvania ; 3University of South Carolina, Charleston, South Carolina ; 4University of Pittsburgh, Pittsburgh, Pennsylvania ;
5University of Pittsburgh, Pittsburgh, Pennsylvania. (Tracking ID # 10961)
BACKGROUND: Accurate analysis of health problems facing rural residents, as well as the implementation of programs to address them, depends on how well rurality is measured. Currently, rural classification systems at the small-area level include those based on the Rural Urban Commuting Area (RUCA) system and a relatively new measure, the Index of Relative Rurality (IRR). The IRR has the potential to be used at
the small-area level but has been demonstrated in analyses only at the large-area (county) level. We describe the development and demonstrate the application of a ZIP code-level Index of Relative Rurality (IRR) classification system that can be used to delineate the degree of rurality at the small-area level. We compare how the choice of classification system affects how geographic areas and the populations who reside in these areas are defined as rural.
METHODS: Data from the 2000 US Census and from the United States Department of Agricultures Economic Research Service (ERS) were linked to Veteran clinical and demographic(including residential address) data extracted from the Veterans Administration Pittsburgh Health System administrative and clinical records, which consisted of 7,608 Veterans with diabetes living in Ohio, Southwest Pennsylvania and West Virginia having recorded a primary care visit in 2008.The ERS data provided the ZIP code RUCA rurality measure associated with each Veteran address. A ZIP code-level IRR classification system was developed using 4 Census-derived measures: residential area-level population, population density, degree of urbanization, and distance to Metropolitan Statistical Area (MSA) from Veteran address. An IRR score of 0 is assigned to the least rural (most urban) geographic area, and a score of 1 is assigned to the most rural. RESULTS: When using the 4-tier (Urban, Large Rural, Small Rural, Isolated Rural) RUCA classification system, fewer than 5% (137/7570) of Veterans with diabetes lived in rural areas. When using the IRR classification system, when rural was defined as 0.4, 21% (1597/ 7570) of Veterans with diabetes lived in rural areas. Nineteen percent (1434/7608) of Veterans with diabetes had addresses that could not be geocoded to a specific latitude and longitude because patient addresses were either post office boxes or rural routes. These addresses were more likely to be located

in rural areas compared to urban areas when using ZIP code information as a proxy for address. Using the 4-tier RUCA classification system, 12% (137/371) of addresses that could not be geocoded were categorized in rural areas compared to 8% (1297/7199) in Urban areas; when using the IRR classification system, 48% (710/1597) of those living in more rural areas (IRR 0.4) could not be geocoded compared to 14% (762/6011) in more urban areas (IRR <0.4). CONCLUSION: The ZIP code-level RUCA classification system compared to the IRR appears to more narrowly define what geographic areas/ populations are rural. Results using the ZIP code-level IRR classification system are comparable to those obtained from using RUCA codes, but using the IRR classification system has the advantages of being more flexible methodologically and easier to interpret than using RUCA codes.

SENIORS UNNECESSARILY COMPLICATE THEIR HOME MEDICATION REGIMENS POST-DISCHARGE

Lee Lindquist 1; Lucy Lindquist 2; Lisa Zickuhr 1; Elisha Friesema 1; Michael Wolf1. 1Northwestern University, Chicago, Illinois; 2Walgreens, Chicago, Illinois. (Tracking ID # 10965)

BACKGROUND: Following hospitalization, seniors have multiple medication changes and new instructions. Seniors also frequently receive medication instructions from many sources. The universal medication schedule (UMS) was recently proposed for standardizing prescribing practices to four daily time intervals which would simplify regimens and potentially improve adherence. We aimed to determine whether seniors consolidate their medications following a hospital discharge, or if there was evidence of unnecessary regimen complexity.

METHODS: Face to face interviews were performed by study nurses with 200 seniors 70 yrs in their homes in the community one month following hospital discharge. At one month, subjects would have developed a routine schedule for taking their medications. During the home visit, the study nurse asked the subject to demonstrate how they

took their medications in a normal day. The nurse visualized where the medications were stored and whether or not a pill box was used. Information on times of day, locations of med, and reasons for each were recorded. Following the interview, research assistants entered their medication lists and calculated the number of times in a day the subject took their medications. Two health care professionals (a pharmacist and a physician) blinded to the actual use of the patient were given the medication regimens of each patient. They were asked to determine the fewest number of times a day that a patient could take the regimen. A third healthcare professional served as a tie-break.

RESULTS: Of 200 seniors [mean age 83.0 yrs, 57% female], 152 (76%) had medication changes at hospital discharge. Medication regimens could be simplified for 85 (42.5%) patients. Of those seniors who were not consolidating their medications, 53 (26.5%) could have had the number of times a day medications were taken reduced by 1; 26 (13.0%) could have reduced by 2; and 6 (3.0%) could have reduced by 3. Medication regimen interrater reliability between the pharmacist and physician (kappa) was 0.845. The three most common causes of overcomplexity of medication regimens were (1) misunderstanding medication instructions (i.e. taking cholesterol lowering medications very late at night), (2) concern over absorption of drugs (i.e. before or after meals), and (3) perceived drug-drug interactions. Pillboxes were used by 99 (49.5%) of subjects but usage did not significantly correlate with simplified regimens.

CONCLUSION: Over forty percent of seniors aged 70 and older overly complicate their medication regimen following a hospitalization. This lack of consolidation potentially impedes medication adherence. Health care professionals should ask patients to explicitly detail the number of times medication consumption occurs in the home. Home nurse visits may also be useful to better ascertain true medication usage. In exploring the reasons behind the complexity, patients and health care professionals need improved education and communication about medication usage.

READABILITY OF PATIENT EDUCATION MATERIALS LINKED TO ELECTRONIC HEALTH RECORDS

Lauren Stossel 1; Nora Segar 2; Peter Gliatto 2; Reena Karani2. 1Mount Sinai School of Medicine, New York,

New York; 2Mount Sinai Medical School, New York, New York. (Tracking ID # 10968)
BACKGROUND: Ample patient education materials (PEMs) are available on the internet. However, many are written at high school or college reading levels. This renders them inaccessible to the average Medicare beneficiary, who reads at a 5th grade level, and the average US resident, who reads at an 8th grade level. Currently, electronic health record (EHR) providers partner with companies that produce PEMs. This allows clinicians to access PEMs without navigating away from the patients electronic medical record during visits. Because institutions are indirectly endorsing these PEMs through the EHRs they purchase, it is crucial to assess their readability. Our goal was to assess the readability of PEMs provided by popular EHR vendors. We hypothesized that a majority of these PEMs are written above target readability, defined as at or below an 8th grade reading level.
METHODS: Per a 2009 report by Modern Healthcare, 26% of US hospitals use Meditech as their EHR supplier. Meditech uses PEMs from Micromedex, Medline, and Lexicomp. These PEM databases are also freely accessible in most academic hospitals. Based on proportions assuming 20,000 PEMs, 50% of PEMs above target readability, a 10% margin of error, and alpha 0.05, we randomly sampled 100 disease-matched PEMs from each of these three databases (n=300 PEMs). Grade reading level needed to read the PEMs was calculated using three
validated indices endorsed by the Center for Medicare and Medicaid Services as being appropriate for assessing readability of PEMS: SMOG, Gunning Fog, and Flesch-Kincaid. These indices vary in stringency, and are based on the number of syllables per word as well as sentence length. We calculated the percentage of documents that were above target readability, and used an ANOVA to compare the average readability scores of each database.
RESULTS: Thus far, we have analyzed 50 disease-matched PEMs from each of three PEM databases. The percentage of each databases PEMs that are above target readability are shown in Table 1, as well as median grade levels and grade level ranges for each databases PEMs. Based on the Gunning Fog index, the ANOVA showed a significant difference in the average grade reading levels of the PEMs from these sources. Micromedex had the lowest average reading level (9th grade) compared to 10thgrade for Medline and Lexicomp ($p<.001$).
CONCLUSION: The vast majority of PEMS available through the most widely used EHR are written at reading levels considerably higher than that of the average US adult. Given health literacys enormous impact on our healthcare system, it is crucial that EHR vendors provide educational materials that are written at appropriate reading levels designed for comprehension by patients at all levels of health literacy.
HIRING AND TRAINING PROCESSES OF AGENCIES SUPPLYING PAID CAREGIVERS TO OLDER ADULTS Lee Lindquist 1; Kenzie Cameron 1; Joanne Messerges-Bernstein 1; Elisha Friesema 1; David Baker1. 1Northwestern University, Chicago, Illinois. (Tracking ID # 10972)
BACKGROUND: Seniors frequently rely on the assistance of paid, non-family caregivers to maintain independence in their homes. Caregivers often are asked to provide medication reminders, transportation to physician appointments, and support for activities of daily living. As the demand for caregivers increase, agencies or private businesses are supplying caregivers to seniors. No prior studies have examined what, if any, screening processes agencies use in selecting caregivers or what training is provided to the caregivers.
METHODS: We aimed to identify screening and training practices of agencies that provide paid non-related caregivers to seniors. Further, we assessed differences between caregiver salaries and agency charges. This study was considered exempt by the Northwestern University IRB. We phoned 432 agencies that advertised to supply home health care and caregiver services in senior-dense areas of Illinois, Wisconsin, Indiana, Arizona, and Florida. Agencies that (1) had 2 or less employees or (2) did not offer non-nursing home services were excluded. Telephone interviews were conducted with surveyors posing as prospective clients obtaining information on caregivers for a senior with dementia. Agencies were queried about their hiring practices,

training, supervision, services provided and fee schedules.
RESULTS: Of the 432 caregiver agencies contacted, 139 fit the inclusion criteria. Of those surveyed, all performed screening procedures; 98%

perform a criminal background check at the state level, but only 55% perform a federal check. Other screening measures include phoning references (100%), drug screening (33%), checking driving records (30%), requiring proof of auto insurance (4%), credit check (5%), and psychological evaluation (2%). Some agencies stated that they perform an elder abuse record check, social security number trace, national caregiver background check, circuit court access program medical assistant exclusion list, and state caregiver check. On further investigation, we found no evidence of these databases and were unable to verify their existence. All agencies reported that caregivers could assist with reminding clients of medications, accompanying seniors to physician appointments, and following physician orders. Although these activities require strong health literacy, no agencies reported assessing potential caregivers health literacy. Agencies primarily determined skill sets through self-report via questions of the caregiver (100%) during the hiring interview. Training of caregivers was extremely variable and included providing a manual, post-hiring training in the home of the senior by a care manager or nurse, shadowing other caregivers, or family effort after hiring. The range of time spent on training was 8 hours to 4 days. On average, agencies charged seniors an hourly rate of $19.31 ($12-$28). Caregivers received $8-10 an hour on average from prior reports. Of the agencies, 64% did not provide health insurance for their employee caregivers.

CONCLUSION: Using an agency to hire caregivers may give seniors and their families a false sense of security regarding the background and skill set of the caregivers. Recent studies have shown that caregivers make errors on medication regimens. More stringent screening, education, and training of caregivers by agencies are needed to ensure adequate care of their senior clients.

EFFECTS OF MEDICARE PRESCRIPTION DRUG COVERAGE ON NON-DRUG MEDICAL SPENDING J. Michael McWilliams 1; Alan M Zaslavsky 1; Haiden A Huskamp1. 1Harvard Medical School, Boston, Massachusetts. (Tracking ID # 10977)

BACKGROUND: The Medicare prescription drug benefit (Part D) has increased use of prescription drugs, decreased out-of-pocket spending for prescription drugs, and decreased cost-related non-adherence among elderly adults. The national effects of Part D on hospitalization rates and non-drug medical spending, however, have not been clearly defined.

METHODS: We used longitudinal survey and linked Medicare claims data from the nationally representative Health and Retirement Study to measure quarterly non-drug medical spending and utilization from 20042007 among 3,224 elderly beneficiaries reporting less generous prescription drug coverage (drugs partially or not at all covered) and 2,495 reporting more generous coverage (drugs mostly or completely covered) in 2004. To estimate effects of the implementation of Part D, we fitted generalized linear models comparing non-drug utilization and spending before and after 2006 by prior drug coverage. We estimated these effects for the entire cohort, for adults with drug-sensitive chronic conditions, and for adults with low incomes. For comparison, we conducted similar analyses for a control period from 20022005, prior to Part D implementation. Applying a similar analysis to biennial survey data, we compared changes from 20042008 in prescription drug coverage, out-of-pocket spending, and cost-related non-adherence for beneficiaries with less or more generous drug coverage in 2004. We then compared these differential changes to differential changes occurring in a control cohort from 20022004. Comparisons were adjusted for baseline sociodemographic and health characteristics, the complex
survey design, repeated measures, survey non-response, and missing claims due to Medicare Advantage enrollment.

RESULTS: After the first quarter of 2006, spending on acute and post-acute care tended to be lower for beneficiaries with less generous prior drug coverage ($313/quarter; P=0.08) than was expected from preceding trends and changes in spending for beneficiaries with more generous prior drug coverage. Spending on acute

and post-acute care after 2006 was significantly lower than expected for beneficiaries with drug-sensitive chronic conditions ($413/quarter; P=0.03) and low incomes ($781/quarter; P=0.01) who had less generous drug coverage in 2004. Hospitalization rates also tended to be lower than expected after 2006 for those with less generous prior drug coverage (0.014/ quarter; P=0.08). Spending on other non-drug services did not differentially change after 2006 for beneficiaries with less generous prior drug coverage ($4/quarter; P=0.97). In a control cohort from 20022005, spending on acute and post-acute care did not differentially change after the first quarter of 2004 for beneficiaries with less generous drug coverage in 2002 ($19/quarter; P=0.90). Beneficiaries who had less generous drug coverage in 2004 reported better drug coverage (+20.5 percentage points with more generous coverage; P<0.001), lower out-of-pocket spending on drugs ($152/month; P=0.002), and less cost-related non-adherence (2.4 percentage points; P=0.04) than was expected in 2008 in the absence of Part D.

CONCLUSION: The implementation of Medicare Part D was associated with lower spending on acute and post-acute care for beneficiaries with less generous drug coverage before 2006. These benefits were concentrated among those with drug-sensitive chronic conditions, for whom increased use of prescription drugs might prevent costly complications, and among those with low incomes, who were less likely to be able to afford prescribed medications before 2006 and more likely to qualify for subsidized Part D coverage without a coverage gap. Hence, the costs of provisions in the Patient Protection and Affordable Care Act to reduce cost-sharing in the doughnut hole of standard Part D coverage may be partially offset by reduced Medicare spending on Part A services for these groups. Moreover, these findings would support policies incentivizing Part D plans to design drug coverage and formularies to minimize Part A spending.

RELIABILITY OF AN INTERACTIVE COMPUTER PROGRAM FOR ADVANCE CARE PLANNING Jane R. Schubart 1; Michael Jay Green 1; Megan Whitehead 1; Elana Farace 1; Benjamin H. Levi1. 1Penn State College of Medicine, Hershey, Pennsylvania. (Tracking ID # 10978)

BACKGROUND: The 1990 Patient Self Determination Act requires healthcare institutions to inform patients about advance directives (ADs) and offer individuals the opportunity to express their wishes regarding end-of-life care. Despite widespread efforts to promote ADs, completion rates remain low. Making Your Wishes Known: Planning Your Medical Future is an interactive computer program that guides individuals through the process of advance care planning. The program explains common health conditions that can impair patients communication of preferences, as well as interventions that commonly involve life or death decisions. Users are helped to reflect on and articulate their personal values/goals relating to medical care, disability, death/dying, and quality of life (QoL). The program includes a decision aid that translates health care preferences into a detailed AD document. An important step in establishing the validity of this decision aid is to demonstrate reliability in generating an AD that reflects an individuals values/preferences and, in the absence of major life changes, remains stable over time. This study examines the test/re-test reliability of the AD document generated by the computer program.

METHODS: Participants were recruited from a list of patients who expressed interest in advance care planning. Inclusion criteria were age >30, English speakers, >8th grade reading level, cognitively able to use the program, and not depressed. Participants completed the decision aid at 2 study sessions, 46 weeks apart, each lasting 13 hours. At the second session, participants completed a questionnaire about interim life events that might influence responses to end-of-life healthcare decisions. Generalizability Theory (GT) was used to assess multiple reliability indices and to determine the relative importance of various sources of error using 2 scales the medical Wishes scale and the QoL scale. Wishes scores involved 8 binary items (e.g., kidney dialysis, mechanical ventilation, feeding tube) under 5 clinical scenarios (stroke that would/would not improve, coma that was/was not reversible, and dementia). QoL scores were determined by the values statements selection.

RESULTS: 24 participants completed the study (19 women and 5 men; ages 4389). Under classical theory

testing, both the Wishes and QoL scales had high internal consistency in both time periods (Cronbach Coefficient Alpha=0.830.95, 0.860.89) meaning that the items comprising them fit together). Test-retest reliability was moderate to high for QoL (Pearson Correlation Coefficient=0.83). Using the GT models, reliability was low for Wishes across the scenarios (G-index=0.21), implying that rankings for specific treatments tend to vary, but improved (G-index=0.49) if the scenario was held constant, suggesting that under some scenarios the reliability of the scale may actually be high. The G-index for QoL was high (G-index=0.81), indicating that formulations of general goals/values remain stable across time. The study construct did not take into account the influence of the decision aid itself on individuals Wishes rankings.
CONCLUSION: Using our computer-based decision aid, specific wishes vary over time, but general values regarding quality of life remain consistent. Future studies will examine whether individuals wishes for specific medical treatments show greater stability after accounting for the educational impact of the decision aid.
HEALTH BELIEFS OF STROKE SURVIVORS IN AN URBAN COMMUNITY Revathi Balakrishnan 1; Judith Z. Goldfinger 2; Kezhen Fei 2; Carol R. Horowitz2. 1Mount Sinai School of Medicine, NEW YORK, New York; 2Mount Sinai School of Medicine, New York, New York. (Tracking ID # 10981)
BACKGROUND: Secondary prevention of stroke depends on the control of hypertension and hyperlipidemia and use of anti-thrombotic medications. Fewer than half of all stroke survivors have these risk factors controlled, and recurrent strokes and inadequate risk factor control are more common in minority populations. A research team formed from a community-academic partnership aimed to identify health beliefs that may contribute to poor risk factor control among stroke survivors in the predominantly minority population in Harlem and Bronx, New York for potential areas of intervention.
METHODS: Adults over 40 years of age with a history of stroke or transient ischemic attack (TIA) within the past 5 years were recruited from community and clinical sites to enroll in the Prevent Return of All Inner-city Strokes through Education (PRAISE) trial. Upon enrollment, participants completed a survey that assessed patient factors related to recurrent stroke, including demographics, health status, social support, and relationship with doctors. Blood pressure, direct LDL cholesterol and body mass index (BMI) were also measured. The composite outcome of the study was control of all three primary risk factors for stroke: blood pressure <140/90 mmHg, LDL cholesterol <100 mg/dL, and reported regular use of an anti-thrombotic.
RESULTS: Of 330 stroke and TIA survivors, 46% were African American, 33% were Hispanic, and 13% were Caucasian; 64% were female. Most participants (69%) reported residual stroke symptoms and most (70%) worried about future strokes, but only 19% identified blood pressure and only 13% identified cholesterol as major risk factors for stroke. Only one-third (31.5%) had the composite outcome of all three primary risk factors controlled. Half of the study participants reported their blood pressure was well controlled; of these people, nearly one-third (28%) did not have their blood pressure at goal. Of the 39% who reported their cholesterol was well controlled, 38% did not have their LDL at goal. While nearly all (93%) participants were under the care of a primary care doctor, one-third did not strongly believe that medications help prevent future strokes, 35% did not fully understand their medications, nearly half forget to take medications, and half believed doctors prescribe too many medications. Also, 47% believed racial discrimination occurs in doctors offices and only 23% believed that Blacks and Latinos could receive the same care as Caucasians. CONCLUSION: In this urban, predominantly minority population of stroke survivors, despite the presence of symptoms, concern for future strokes, access to a primary care physician, and a desire to prevent recurrent strokes, there remains a gap in the knowledge of stroke risk factors and the role that medications fulfill in their control. This is reflected by the inadequate use of anti-thrombotic medication, poor control of blood pressure and LDL cholesterol. In addition, this study revealed perceived racial disparities in doctors offices and access to care. These findings highlight the need for interventions that can facilitate health education among those at risk for future strokes and the need to foster more effective relationships with healthcare providers in the urban community.
RELIANCE ON VA OUTPATIENT SERVICES BY MEDICARE-ELIGIBLE VETERANS Chuan-Fen Liu 1; Willard

G. Manning 2; James F. Burgess 3; Paul L. Hebert 4; Christopher L. Bryson 5; John Fortney 6; Mark Perkins 5; Nancy D. Sharp 5; Matthew L. Maciejewski7. 1Department of Veterans Affairs, Seattle, Washington ; 2Department of Health Studies, University of Chicago, Chicago, Illinois ; 3VA Boston Healthcare System; School of Public Health, Boston University, Boston, Massachusetts ; 4VA Puget Sound Health Care System; Department of Health Services, University of Washington, Seattle, Washington ; 5VA Puget Sound Health Care System, Seattle, Washington ; 6Central Arkansas Veterans Healthcare System; University of Arkansas for Medical Sciences, North Little Rock, Arkansas ;
7Durham VA Medical Center; Duke University Medical Center, Durham, North Carolina . (Tracking ID # 10984)
BACKGROUND: Patients who obtain outpatient care in more than one health care system disrupt continuity of care and may have a lower quality of care and worse health outcomes, particularly among individuals with complex chronic conditions. The Department of Veterans Affairs (VA), the largest integrated health care system in the United States, served 5.5 million veterans in 2008. However, a significant proportion of veterans who use the VA also have coverage through Medicare. To transform primary care delivery, VA is implementing a patient centered medical home model system wide using the team-based approach to provide patient-centered care to further improve access, coordination, and continuity of care. This study examines longitudinal changes in reliance on VA healthcare system for primary and specialty care over four years among a cohort of VA Medicare-eligible veterans.
METHODS: This is a retrospective cohort study. The study sample included 15,520 Medicare-eligible veterans who used VA primary care in 2000. We merged VA administrative and Medicare claims data to examine outpatient use during Fiscal Years (FY) 20012004. Patients

were censored at the year of death. VA outpatient care reliance was defined as the proportion of total (VA/Medicare) visits received in VA for primary care or specialty care. We estimated VA outpatient care reliance using beta-binomial regressions because of a U-shape distribution indicating that significant number of veterans concentrated at high and low VA reliance.
RESULTS: Of 869,000 primary and specialty care visits in the study period, 39% occurred within VA. VA primary care reliance was substantially higher than VA specialty care reliance (66% vs. 50% in FY2001; $p<0.001$)) and both primary and specialty care reliance decreased throughout the study period (55% vs. 32% in FY 2004; $p<0.001$). Significant shifts occurred at both extremes of VA reliance. From FY2001 to FY2004, the proportion of patients in the top decile of VA
primary care reliance decreased from 38% to 30%, while the proportion in the bottom decile doubled from 10% to 20% (Figure). Similarly, the proportion of patients in the top decile of VA specialty care reliance decreased from 24% to 13%, while the proportion in the bottom decile doubled from 23% to 47%.
CONCLUSION: VA primary and specialty care reliance by a cohort of Medicare-eligible VA primary care patients decreased substantially over 4 years. By the fourth year, only half of primary care visits and one-third of specialty care visits occurred in VA for this population of primary care users. Decreasing VA outpatient care reliance may have had substantial impacts on chronic disease management and continuity of care. Increasing use of non-VA services complicates VAs implementation of patient centered medical home models and performance measurement.

RISK OF RESIDENT CLINIC HANDOFFS: SHOWING UP IS HALF THE BATTLE Amber T. Pincavage 1; Shana Ratner 1; Megan Prochaska 1; Meryl Prochaska 1; Julie Oyler 1; Vinny Arora1. 1University of Chicago, Chicago, Illinois. (Tracking ID # 10986)
BACKGROUND: Continuity of care in the primary care setting is associated with greater patient satisfaction and fewer hospital admissions. Nationally, many patients experience a change in their PCP when departing Internal

Medicine (IM) residents handoff their patients to junior residents. No studies to date have examined the specific patient risks relating to these handoffs. Our study aims to characterize patients at higher risk of adverse events after a clinic handoff.
METHODS: In June 2010, graduating IM residents listed clinic patients they perceived to be at high risk during the clinic handoff on a signout worksheet which included reasons for high risk status, target follow-up date, and tasks to be done. During a designated handoff meeting, departing residents discussed their patients with the junior resident taking over their clinic. Clinic coordinators used worksheets to facilitate scheduling of patients. For all patients, signouts and charts were reviewed to determine if and when patients were scheduled and if they saw their new PCP. We also examined associations between follow-up, patient factors (no show rates), and outcomes (ED visits or hospitalizations) in the three months after the transition. PGY2 residents assuming care we resurveyed regarding their beliefs of the clinic handoff process.
RESULTS: Thirty graduating residents identified 258 clinic patients as high risk. Mean age was 61 (range 2795), 63% were female, and on average the patients were transitioning to their 3rd PCP in 5 years. Patients were deemed high-risk due to complexity (59%), new diagnoses (28%), psychiatric diagnoses (18%), and non-adherence (12%). Nearly all patients (97%, 250/258) were scheduled for their follow-up appointment. However, one third (29%, 75/258) of patients no showed or cancelled their first visit with their new PCP. Ultimately, less than half (44%, 113/258) of patients saw the correct PCP. The average time between visits with the old and new PCP was 110 days (range 11 to 350). Six months after the handoff, one fifth (19%, 50/258) of patients had not yet been seen. A significantly higher overall No Show rate (NSR) (reported in Epic) was more likely to be noted among patients missing their first visit with their new PCP (22% vs. 16% NSR, $p<0.001$), transitioning to the wrong PCP (19% vs. 16% NSR, $p=0.05$), and those lost to follow-up (21% vs. 17% NSR, $p=0.02$). Overall, 26% (68/ 258) of patients visited the ED or were hospitalized during the 3 months after the handoff. Patients who missed at least one appointment with their PCP in the last year were more likely to have an acute care visit in the ED or hospital (33% vs. 22%, $p=0.038$). Most (95%) PGY-2 residents completed surveys. While half (47%) of residents worried about missing important patient data during the transition, a similar proportion (48%) reported they do not take ownership of a patient until the first clinic visit.

CONCLUSION: Resident clinic handoffs are a vulnerable time for high risk patients. While most patients were scheduled for appointments, over half were not seen by the correct resident who was to take over their care. Patients who miss appointments are especially at risk of adverse consequences during this care transition. Because residents do not feel responsible for patients until after their first clinic visit, improving patient attendance to the first visit with their new PCP is imperative. Future interventions to improve resident clinic handoffs should incorporate these findings.
ASSOCIATION OF INCARCERATION WITH TRAUMA, SUBSTANCE USE RELATED HEALTH CONSEQUENCES, AND HEALTH CARE UTILIZATION Nicole Redmond 1; LeRoi S. Hicks 2; Debbie M. Cheng 3; Donald Allensworth-Davies 4; Michael R. Winter 4; Jeffrey H. Samet 3; Richard Saitz3. 1Brigham and Womens Hospital, Dorchester, Massachusetts ;
2Brigham and Womens Hospital, Boston, Massachusetts ; 3Boston Medical Center, Boston, Massachusetts ; 4Boston University School of Public Health, Boston, Massachusetts . (Tracking ID # 10993)
BACKGROUND: Recently released inmates are at significantly higher risk of death due to drug overdose, suicide, homicide, and cardiovascular disease relative to the general population. Whether these mortality differences are due to the higher prevalence of drug dependence among inmates, or due to an independent effect of incarceration, is not clear. Among substance dependent adults, we explored the effects of incarceration on outcomes that may be intermediate markers for mortality: a) traumatic injuries, b) substance use-related health consequences, and c) hospital and/or emergency department (ED) utilization.
METHODS: We analyzed survey data (baseline, 3, 6, and 12 month follow-up) collected for the Addiction Health

Evaluation and Disease management (AHEAD)study, a randomized clinical trial to test the effectiveness of chronic disease management for substance dependence in primary care. The following 3 outcomes (past 3 months, assessed at 3, 6, and 12 months) were evaluated: (1) any traumatic injury; (2) substance use related health consequences (defined as any of the following while using drugs and/or alcohol: accident, suicide attempt, physical/sexual assault, or an overdose requiring ED/medical attention); and (3) a composite variable for hospital and/or ED utilization excluding addiction treatment or detoxification (defined as reporting yes to any medical or psychiatric hospitalization or any ED visit). The main independent variable was self-reported recent incarceration, defined as spending at least one night in jail or prison <3 months prior to the research interview. In longitudinal analyses, incarceration was modeled as a time-dependent and time-lagged (assessed at the interview prior to outcome) variable. Covariates included sociodemographic and clinical characteristics, drug dependence type (alcohol, drug, or both, determined by diagnostic interview), randomization group and past 3-month value of the outcome at baseline (i.e., at study entry). We used generalized estimating equations logistic regression models to evaluate the association between recent incarceration and each of the three dichotomous outcomes, adjusting for all covariates.
RESULTS: Of 553 subjects, 404 (73%) were male with a mean (SD) age of 38.3 (10.1) years; 260 subjects (47%) were non-Hispanic White, 175 (32%) were non-Hispanic Black, 73 (13%) were Hispanic, and 45 (8%) were of other race/ethnicity. Other cohort features were the following: 95 (17%) were alcohol dependent only, 144 (26%) were drug dependent only, and 314 (57%) were both drug and alcohol dependent; 93 (17%) reported recent incarceration at study enrollment. Recent incarceration was not significantly associated with traumatic injury (adjusted odds ratio [AOR]=1.10, 95% CI: 0.73-1.65) or health care utilization (AOR= 0.92, 95% CI: 0.68-1.24). However, recent incarceration was associated with higher odds for substance use-related health consequences (AOR=1.43, 95% CI: 1.03-1.98).
CONCLUSION: Although larger samples and/or longer follow-up may be necessary, we did not detect significant effects of incarceration on injury or health care utilization, despite adjustment for sociodemo-graphic, clinical and substance dependence characteristics. However, among people with alcohol and/or drug dependence, incarceration appears to be associated with higher odds of substance use related health consequences. Substance use related health consequences may explain, at least in part, the increased risk of death faced by former inmates.
TOTAL RECALL IS A MYTH: ASSESSING PATIENT RECALL OF HEALTH INFORMATION PRESENTED USING ALTERNATIVE FACTS &MYTHS MESSAGE FORMATS Kenzie A. Cameron 1; Tiffany Brown 1; Michael E. Roloff 2; Elisha M. Friesema 1; Sara Hauber 1; Jason A. Thompson 1; David W. Baker1. 1Northwestern University Feinberg School of Medicine, Chicago, Illinois; 2Northwestern University, Evanston, Illinois. (Tracking ID # 10995)
BACKGROUND: Preventive health messages using a Facts &Myths format attempt to reinforce accurate information and refute false information. Some research cautions against the use of such a format, reporting that myths may be misremembered as facts. However, communication research proposes that a message containing original arguments (facts), counterarguments (myths), and a refutation of counterarguments will be more persuasive than a facts only message. Given the ubiquity of the Facts &Myths format, we sought to identify how alternative Facts &Myths formats affect patients retention of accurate information.
METHODS: We conducted a randomized clinical trial of four alternative messages related to influenza/influenza vaccination. The control message was a Flu Vaccine Facts &Myths flyer disseminated by the Centers for Disease Control and Prevention (CDC control), which presents facts, myths, and some general evidence in support of the facts. Three alternative message formats were created: (1) Facts Only, (2) Facts &Myths, and (3) Facts, Myths, and Refutations, a message including additional evidence to refute the myths presented. Patients were recruited from a General Internal Medicine practice between September 2009 - February 2010 (N=126), completed a telephone pre-test, and were randomized to receive one of the 4 messages. The message was

mailed to patients one week prior to a scheduled physician visit. This abstract reports on a subset of patients (N=87) who reported receiving and reviewing a message, and who completed an in-person interview immediately prior to their visit. Participants were read 8 statements and asked to recall if the statements had been (1) presented as a fact, (2) presented as a myth, (3) presented, but I dont recall if it was a fact or a myth, or (4) not presented in the mailed message. Responses were analyzed to assess recall accuracy (range 08) for each of the 4 message formats and the difference among message formats.
RESULTS: Participants accurately recalled the presentation of a mean of 4.44 statements (SD=2.02). An ANOVA demonstrated significant differences in recall accuracy between message formats (F=8.65, p<.001): CDC control - M=4.77 (SD=1.82); Fact Only - M=3.00 (SD=1.74); Facts &Myths - M=4.52 (SD=1.97); and Facts, Myths and Refutations - M=5.76 (SD=1.65). Scheffes post-hoc analysis revealed significant differences in recall accuracy between the Fact Only and Facts, Myths and Refutations (p<.01); and Fact Only and CDC Control (p<.05) formats; the difference in recall accuracy approached signifi-

cance between the Fact Only and the Facts &Myths formats (p=.052). No other significant differences emerged between message formats on recall accuracy.
CONCLUSION: When designing patient education messages we need to understand what information receivers will retain, and their recall of the veracity, or truth value of information presented in the messages. Participants receiving the Fact Only format demonstrated lower recall accuracy than all other formats, suggesting that merely presenting individuals with factual information does not automatically assure recall accuracy. Presenting participants with alternatives that included facts and myths resulted in less than ideal recall, yet recall was significantly better than for a message presenting only facts. Thus, our study found no evidence to suggest that presentation of facts and myths in a message is counterproductive to recall accuracy.

EFFICACY AND TOLERABILITY OF ONCE-DAILY GABAPENTIN EXTENDED-RELEASE(G-ER)FORTHETREATMENTOFPOSTHERPETIC NEURALGIA IN PATIENTS AT LEAST 65 YEARS OLD

Michael Sweeney 1;
Rekha Sathyanarayana1. 1Depomed, Inc, Menlo Park, California. (Tracking ID # 10996)

BACKGROUND: The risk, severity and duration of postherpetic neuralgia (PHN) all increase with subject age. Furthermore, treatment decisions must consider the greater likelihood of concomitant medications in older patients. Immediate-release gabapentin is approved for treatment of PHN and has a low propensity for drug-drug interactions; but requires multiple daily dosing and is associated with a high frequency of dizziness and somnolence. The efficacy and tolerability of once-daily gabapentin extended-release (G-ER; 1800 mg) for treatment of PHN has recently been examined in a double-blind, placebo-controlled, Phase 3 study. In this analysis of data from that study, we examined the efficacy and tolerability of G-ER in patients who were at least 65 years old and subsequently compared these patients with the overall study population.
METHODS: Patients with PHN of duration >6 months and an average daily pain (ADP) score >4 were enrolled. After 1 week of baseline assessments, patients were randomized to G-ER (titrated to 1800 mg over 2 weeks) or placebo with their evening meal for a total treatment period of 10 weeks, followed by 1 week of dose tapering. The primary efficacy endpoint was baseline observation carried forward change in ADP. Rates of adverse events also were recorded. The primary efficacy endpoint and rates of adverse events also were assessed separately in patients who were >65 years old.
RESULTS: The overall intent-to-treat population included 450 patients (G-ER, n=220; placebo, n=230); 280 patients were at least 65 years old (G-ER, n=139, placebo, n=141). The safety population included two additional patients (one <65 years old, placebo; one >65 years old, (G ER). In the overall study population, the mean +/SD baseline ADP scores in the G-ER group and placebo groups were comparable (6.6+/1.4 vs

6.5+/1.4, respectively). Comparable baseline scores also were observed in patients >65 years old (G-ER, 6.8+/1.5; placebo, 6.5+/1.3). In the overall study population, ADP scores were reduced significantly at endpoint in the G-ER group when compared with placebo (least squares [LS] mean difference SE, -0.49+/0.20; p=0.0125). Similarly, in patients who were >65 years old, the reduction in ADP scores was significantly greater in the G-ER group compared with placebo (LS mean difference +/SE, -0.65+/0.25; p=0.0088). Compared with G-ER-treated patients in the overall population, a smaller proportion of G-ER-treated patients in the older subgroup reported at least 1 adverse event (52.5% vs 47.1%, respectively), but the proportions were comparable for the placebo groups of the overall population and of the older subgroup (39.4% vs 39.7%, respectively). Dizziness and somnolence in G-ER treated patients were observed less frequently in the older subgroup compared with the overall population (dizziness:10.7% vs 11.3%, respectively; somnolence: 4.3% vs 5.4%, respectively) although those frequencies were higher than observed in the respective placebo groups (dizziness: 2.8% and 1.7%, respectively; somnolence:1.4% and 3.0%, respectively). No other adverse events were observed in >5% of any group of the overall population or older subgroup and consistently more frequently in the G-ER group compared with placebo. CONCLUSION: G-ER provided significant reduction in pain intensity compared with placebo in both the overall study population and in the older subgroup of patients. G-ER was well tolerated overall and in the older subgroup of patients. The frequencies of dizziness and somnolence in G-ER treated patients, both overall and in the older subgroup, suggest a lower rate than observed in previous clinical trials of immediate-release gabapentin.

Disclosures: This analysis was supported by Depomed, Inc. and Abbott. Medical writing support was provided by Ed Parr, PhD, of Envision Scientific Solutions, and supported by Abbott.

IMPACT OF HOSPITAL TEACHING INTENSITY ON THE QUALITY OF CARE IN HOSPITALS Stephanie K. Mueller 1; LeRoi S. Hicks1.

1Brigham and Womens Hospital, Boston, Massachusetts. (Tracking ID # 10998)

BACKGROUND: Studies examining the quality of care that a patient receives in teaching versus non-teaching hospitals have demonstrated mixed results and many were conducted prior to the implementation of the Accreditation Council for Graduate Medical Education (ACGME) residency work hour restrictions. Thus, a more current examination of the association between hospital teaching intensity and quality of care is overdue.

METHODS: We linked 2008 Hospital Quality Alliance (HQA) and 2007 American Hospital Association (AHA) data for each medical and surgical hospital in the U.S. Main outcome measures included 30 day readmission rate and mortality rate for 3 conditions: acute myocardial infarction (AMI), congestive heart failure (CHF), and pneumonia. The predictor of interest was teaching intensity, defined as number of residents-tobed ratio and classified into either: (1) non-teaching (zero residents/ bed), (2) low teaching intensity (00.25 residents/bed), (3) medium teaching intensity (0.25-0.6 residents/bed) and (4) high teaching intensity (> 0.6 residents/bed). We utilized linear regression to examine the relationship between teaching intensity and each clinical outcome adjusted for hospitals: geographic location, ownership, urban versus rural setting, nursing intensity (nurses/1000 patient days), presence of an ICU, insurance mix, hospital size and presence of hospitalists.

RESULTS: Of the 2423 hospitals reporting quality outcome data, 1528 (63%) were non-teaching, 699 (29%) were low teaching intensity, 116 (5%) were medium teaching intensity, and 80 (3%) were high teaching intensity. After adjustment for hospital characteristics, increasing teaching intensity was significantly linearly associated with readmission rates for all three conditions and conversely associated with mortality rates for AMI and CHF (see Table).

CONCLUSION: In this nationally-representative sample of medical and surgical hospitals we found that increased teaching intensity is associated with higher readmission rates but lower mortality for the most common of inpatient medical diagnoses. Our findings suggest that teaching intensity may be associated with higher quality of inpatient care, but poorer quality transitions of care.

Reference group

DOES MEDICARE PART D PROVIDE ADEQUATE DRUG COVERAGE FOR COMMON HEALTH CONDITIONS Chien-Wen Tseng 1; Tetine Sentell 2; Emmett Keeler 3; Randi Chen 4; R. Adams Dudley5. 1U of Hawaii Dept. of Family Medicine, Honolulu, Hawaii ; 2University of Hawaii Dept. of Public Health, Honolulu, Hawaii ; 3RAND, Santa Monica, California ; 4Pacific Health Research Institute, Honolulu, Hawaii ; 5UCSF School of Medicine, San Francisco, California . (Tracking ID # 11000)

BACKGROUND: Medicare Part D plans provide important drug coverage for 28 million Medicare beneficiaries but vary widely in which drugs they cover and the copayments charged. Such variation among Part D formularies means that some drugs are widely covered by nearly all plans at affordable copayments, while other drugs are covered by only some plans or are covered only with high copayments. To understand the clinical impact of such Part D formulary variation, we examined which common health conditions may currently lack widely covered drugs at affordable copayments. Beneficiaries whose health conditions are treated by these drugs are at greater risk for high out-of-pocket drug costs, cost-related medication non adherence, and losing coverage for their current medications if they seek to switch plans.

METHODS: We analyzed 3,693 Part D plan formularies nationwide using the June 2009 Centers for Medicare and Medicaid Services (CMS) Prescription Drug Plan Formulary and Pharmacy Network Files. Seven common health conditions were examined; hypertension, hyperlipidemia, diabetes, heartburn, asthma or chronic obstructive pulmonary disease (COPD), depression, and Alzheimers. For each condition, we determined whether the corresponding treatment classes had widely covered and affordable drugs. The definition of widely covered was varied from 80% to 90% of plans. The definition of affordable was varied from $15 to $35 copayment per month. Sensitivity analyses found these findings to be robust to the definition of widely covered and affordable, and results are presented for drugs which are covered by 90% of plans at copayments $35.

RESULTS: A total of77 (43%) out of 180 drugs were widely covered and affordable (average coverage: 98% of plans, average copayment $5.10)
and 103 drugs were non-widely covered or had high copayments (average coverage: 48% of plans, average copayment $35).

Out of seven conditions, there were widely covered and affordable drugs in almost all treatment classes for hypertension, depression, heartburn, and dyslipidemia. In contrast, there were no widely covered and affordable drugs for two treatment classes for diabetes (thiazolidinediones and insulin), nor for most treatment classes for asthma/COPD (short or long-acting beta-agonist, steroid inhaler, combination beta-agonist/steroid, other), nor for Alzheimers.

All 77 widely covered drugs were generic, and no brand-name drugs were widely covered by 90% of plans at $35 copayments. Generic drugs were on average covered by 91% of plans (range 13% to100%) and the average copayment was $7. Most but not all of the 99 generic drugs included were widely covered and affordable (77 of 99 drugs=78%). Brand-name drugs were on average covered by 45% of plans and none were widely covered at copayments of $35 or less. The average brand-name copayment was $40 (range $17 to $71, standard deviation $12). CONCLUSION: Medicare beneficiaries who need medications for chronic diseases such as asthma, diabetes, and Alzheimers remain at risk for high out-of-pocket drug costs given the lack of widely covered and affordable drugs in Part D formularies for treating these conditions. Even as the Part D coverage gap is phased out, policymakers need to evaluate how to address variation in formularies and high copayments for drugs for treating these common health conditions.

NO MOMENT WASTED: THE PRIMARY CARE VISIT FOR DIABETIC ADULTS Shari Bolen 1; Paulette Sage 2; Adam Perzynski 2; Kurt Stange2.

1MetroHealth Medical Center/Case Western Reserve University, Cleveland, Ohio; 2Case Western Reserve University, Cleveland, Ohio. (Tracking ID # 11003)

BACKGROUND: Although quality of care guidelines are straightforward, diabetes visits within the primary care

setting are often more complex than adhering to these guidelines. We sought to take an in-depth look at what happens when the health care needs of people with diabetes are addressed by exemplar clinicians caring for the underserved.

METHODS: We conducted a qualitative study of diabetes visits from a safety net primary care clinic with high quality of care scores for diabetes patients. We recruited adults with type 2 diabetes from the 4 primary care physicians at the clinic until no new themes emerged in analyses. We audiotaped, observed, and transcribed the doctor-patient visits. Using a grounded theory approach, two investigators independently coded and analyzed transcripts for all health issues that arose during the visit, and marked whether the physician or patient first initiated the discussion on a particular health issue.

RESULTS: Fifteen patients participated. In a mainly African American (93%) middle-aged (mean age 61 years) female (64%) population, mean blood sugar, blood pressure, and cholesterol were under fairly good control (HbA1c 7.5%, BP 134/81 mmHg, and LDL 100 mg/dl). However, nearly one-half of patients were above recommended goals in at least one category. The mean visit length was 27 minutes (range 1838 minutes) for a scheduled 20 minute visit, and did not include time for finishing the note. The average number of total health issues discussed at the visit was 25 (range 16 to 31), with an average of 15 brought up first by the physician and an average of 10 brought up first by the patient. The health issues were grouped into the following domains from most to least frequently discussed: chronic diseases, prevention, health behavior, social environment, medications, acute symptoms, intrapersonal, and coordination of care. Physicians most frequently initiated discussions in chronic diseases, prevention, and health behavior. Patients most frequently initiated discussions of social environment and acute/new symptoms followed by prevention and health behavior -which were also frequently raised by physicians.

CONCLUSION: Primary care visits by diabetes patients are complex. Emerging new models of primary care delivery and quality measurement should support and allow adequate time to address the complementary priorities of patients and physicians as they work together on the complex tasks of improving patients health.

COGNITION AND CHOICE OF TRADITIONAL MEDICARE OR MEDICARE ADVANTAGE J. Michael McWilliams 1; Christopher C Afendulis 1; Thomas G McGuire 1; Bruce E Landon1. 1Harvard Medical School, Boston, Massachusetts. (Tracking ID # 11006)

BACKGROUND: Since the Medicare Modernization Act of 2003, increased payments to Medicare Advantage (MA) plans have been associated with a dramatic proliferation in the number of plans available to Medicare beneficiaries and more generous benefits for MA enrollees. Too many or overly complex insurance options may result in suboptimal choices by Medicare beneficiaries. In particular, those with cognitive deficits may have difficulty identifying the most valuable option in their enrollment decisions.

METHODS: For 6,672 participants from the nationally representative Health and Retirement Study, we analyzed survey data, linked Medicare enrollment data, and county-level administrative data on MA plans from 20042007, to determine: 1) if the availability of more plans has increased or decreased enrollment in MA; and 2) if beneficiaries with lower cognitive functioning have been less responsiveness to expanded benefits in MA. Logistic regression was used to estimate effects of within-county increases in the number of plans available and generosity of plans benefits on beneficiaries enrollment in MA or traditional Medicare. Generosity of benefits was measured as the expected monthly out-of-pocket costs in MA for a standardized population of beneficiaries, averaged across all plans available in a given county and year. Results were compared by cognitive functioning, which was assessed in surveys by a validated instrument modeled after the Min-Mental State Examination. All analyses were adjusted for sociodemographic and
health characteristics of participants, county fixed effects, the incomplete linkage to enrollment files, and the

complex design of the survey. RESULTS: The mean number of MA plans increased twofold or more each year from 2004 to 2007 in U.S. counties with at least 1 plan. Increases in available MA plans up to 15 were associated with significant increases in MA enrollment (P=0.004), but increases between 1530 plans were not (P=0.84). Increases above 30 plans were associated with significantly decreased enrollment in MA (P<0.001). By 2007, over 95% of study participants faced lower expected out-of-pocket costs in MA than in traditional Medicare with Medigap coverage, based on county-level averages. Decreased expected out-of-pocket costs in MA (more generous benefits) were associated with increased MA enrollment among participants with high cognitive functioning (P=0.02) but not among participants with low cognitive functioning (P=0.56). CONCLUSION: Medicare beneficiaries were less likely to enroll in MA when faced with numerous choices. Those with lower cognitive functioning were less responsive to the generosity of MA benefits in their enrollment decisions. Simplifying choice in MA could improve beneficiaries decisions, strengthen value-based competition among plans, and extend the benefits of choice to seniors with impaired cognition. In particular, the role of insurance exchanges established by the Patient Protection and Affordable Care Act could be expanded to serve Medicare beneficiaries and MA plans.

USINGA REGIONAL HEALTHINFORMATION EXCHANGE TO IMPROVE IDENTIFICATION OF POST-DISCHARGE FOLLOW-UP PROVIDERS Mustafa Fidahussein 1; John Hook 1; Joe Kesterson 1; Martin Were1.

1Regenstrief Institute, Inc., Indianapolis, Indiana. (Tracking ID # 11012)

BACKGROUND: Determining who patients should follow-up with post-discharge is a key step in transitioning care from an inpatient to outpatient setting. Typically, this follow-up provider information is contained within the discharge summary, and inpatient providers rely greatly on it to determine who to communicate the patients hospital course, discharge summary, and any test results returning after discharge. Unfortunately, no studies exist that evaluate how complete and accurate the follow-up information documented in discharge summaries is, and whether strategies exist to improve identification of the providers who discharged patients actually follow-up with after hospitalization. We set out to determine (a) the follow-up patterns of patients discharged from two large hospitals in central Indiana, and (b) the potential role of a regional health information exchange (RHIE) in improving identification of the providers with whom these patients follow-up with post-discharge. METHODS: We performed this study at two large urban Midwestern hospitals (Hospital A and Hospital B) which are served by comprehensive electronic health record systems (EHRs) and which participate in the Indiana Network for Patient Care (INPC) RHIE. The study involved 679 randomly-selected patients (306 from Hospital A and 373 from Hospital B) who were admitted to the General Internal Medicine Hospitalist Services (GIMHS) teams during Jan-Feb 2009 at these institutions. Discharge summaries for the study patients were each reviewed independently by two physicians who abstracted the names of the intended follow-up providers that were mentioned in the summaries. If there were disagreements between the reviewers on whether a particular follow-up provider was mentioned, the reviewers discussed the case to achieve consensus. Electronically stored encounter data from the INPC were also queried to extract all outpatient physician encounter data for the study patients that occurred 1214 months prior to the relevant admission and 35 months after discharge (Jan 1, 2008 -Jun 1, 2009). Using this data, we determined the frequency with which patients actually followed up with the intended outpatient providers,

and also with other providers who were not mentioned in the discharge summary. We also determined how often historical visit information contained in the RHIE could be used to inform likely outpatient follow-up providers for patients, especially when no information about the follow-up providers was available in the discharge summary. RESULTS: Of the 679 study patients, 458 (67%, [180, 59% Hospital A &278, 75% Hospital B]) had at least one follow-up provider mentioned in the discharge summary, with the other 221 (33%, [126, 41% Hospital A &95, 25% Hospital B]) having no follow-up provider mentioned. Of the 458 patients with a

provider mentioned in the discharge summary, 185 (40%, [84, 47% Hospital A &101, 36% Hospital B]) followed-up in clinic with at least one of the mentioned providers, 132 (29%, [61, 34% Hospital A &71, 26% Hospital B]) followed-up with none of the providers mentioned in the summary, and 141 (31%, [35, 19% Hospital A &106, 38% Hospital B]) did not follow-up with any provider. Historical encounter information from the RHIE revealed that of the 317 patients who had a follow-up provider mentioned in the discharge summary and who followed-up post-discharge with any provider, 182 (57%, [83, 57% Hospital A &99, 58% Hospital B]) followed with at least one of the same providers they had been seeing prior to admission. Of the 123 patients who did not have any follow-up providers mentioned in the discharge summary but still followed-up post-discharge with any provider, 58 (47%, [43, 52% Hospital A &15, 16% Hospital B]) followed-up with at least one of the same providers they had been seeing prior to admission. Overall, of the 440 patients who had a clinic visit post-discharge, 240 (55%, [126, 55% Hospital A &114, 55% Hospital B]) saw at least one of the same providers they had visited with prior to their admission. Of the 458 patients that had at least one follow-up provider mentioned in the discharge summary, 182 (40%, [74, 41% Hospital A &108, 39% Hospital B]) were seeing at least one of these providers prior to admission. Of these 182 patients, 94 (52%, [43, 58% Hospital A &51, 47% Hospital B]) followed-up with the at least one of the same providers post-discharge.

CONCLUSION: A care system which relies largely on follow-up provider information contained within discharge summaries is highly inadequate at identifying the actual providers patients follow up with after they are discharged from the hospital. We found that 33% of discharged patients had no follow-up providers identified. Even when follow-up providers were mentioned in the discharge summary, almost a third of the patients still saw other providers. Regional Health Information Exchanges, which contain encounter information that occur after hospital discharge, offer a valuable resource in improving identification of the true follow-up providers for patients discharged from the hospital. Additionally, historical visit information within these systems can help predict who the likely post-discharge follow-up provider will be for patients being discharged from the hospital. We observed that more than half of the patients actually followed up with a provider they had seen prior to the admission. Making this historical provider information available during discharge planning could potentially increase the likelihood that the right follow-up providers will be identified at the time of a patients hospital discharge.

PERCEPTION OF CLINICIAN ROLES AND RESPONSIBILITIES DURING CARE TRANSITIONS OF OLDER ADULTS Nancy L Schoenborn 1; Alicial. Arbaje 2; Kenric A. Maynor 3; Kathryn J. Eubank 4; Joseph A. Carrese5. 1Johns Hopkins Bayview Medical Center, Johns Hopkins University School of Medicine, Baltimore, Maryland ; 2Division of Geriatric Medicine and Gerontology, Johns Hopkins University School of Medicine, Baltimore, Maryland ; 3Geisinger Health System, Danville, Pennsylvania ; 4Geriatrics Section, Department of General Internal Medicine, University of Texas at Southwestern, Dallas, Texas ; 5Division of General Internal Medicine, Johns Hopkins University School of Medicine, Baltimore, Maryland. (Tracking ID # 11019)

BACKGROUND: Older adults with complex care needs frequently require care in multiple settings, and they are at high risk of receiving suboptimal care during care transitions. Clinician roles and responsibilities during care transitions remain poorly defined. We sought to characterize the perceived roles and responsibilities of inpatient- and outpatient-based clinicians during care transitions, and explore barriers to clinicians fulfilling their perceived roles.

METHODS: This was a qualitative study involving one-hour semi-structured in-depth interviews conducted with forty participants directly involved in care transitions of older adults (18 physicians, 3 nurse practitioners (CRNPs), 3 physician assistants (PAs), 10 case managers, 4 social workers, and 2 home care coordinators). These participants were from a variety of settings, including an acute care hospital, a skilled nursing facility (SNF), two community-based outpatient practices, and one home healthcare agency. Interviews explored the roles and responsibilities of clinicians (physicians, CRNPs, PAs) during care transitions of older adults, as perceived by themselves and by others. Audiotapes of the interviews were transcribed, coded, and analyzed,

generating several themes and subthemes.
RESULTS: Participants averaged 45.3 years of age and 17.2 years in practice. Seventy-two percent were women, and 15% were ethnic minorities. Slightly less than half (45%) were from outpatient clinics and home care, 27.5% from an acute hospital, and 27.5% from a SNF. Content analysis revealed several major themes:1) Essential components of clinician roles during care transitions. These included: Review of clinical information upon receiving patient; Communication with patient and family; Communication with multi-disciplinary staff; Medication reconciliation; Assessment of discharge needs and available support at home; Discharge summary; Post-discharge follow up and care; and Communication with clinicians in other settings.2) Tension between routine and ideal roles.
We found differences between what clinicians did routinely and what they would do ideally in transitions. For example, a hospitalist would routinely send the discharge summary to the primary care provider but ideally would call the primary care provider on admission and discharge of the patient.3) Agreement between self and others perceptions of ideal roles.4) Patient and clinician factors prompting clinicians to go the extra mile and move from routine to ideal roles.
Clinicians were more likely to go above and beyond their routine when the patient was medically or socially more complex, in high risk situations such as a major change in status, and when the clinician was personally more invested (e.g., when she knew the receiving clinician personally or developed a strong interest in the patients case).5) Barriers to fulfilling ideal roles.
These included: healthcare system barriers such as reimbursement and staff turnover, care transition process barriers such as lack of access to other providers, and lack of knowledge and education regarding care transitions.
CONCLUSION: This study characterizes the roles and responsibilities of clinicians during care transitions of older adults. We report discrepancies between perceived roles of clinicians in an ideal care transition and actual practice, and we describe perceived barriers to fulfilling the ideal role. We also describe patient and clinician factors that may prompt clinicians to do more than the routine and act closer to the ideal role. Future investigations could explore ways to overcome some of the barriers, and whether to target certain high-risk transitions.

PHARMACY SUPPORT IN VA PRIMARY CARE CLINICS AND MEDICATION ADHERENCE AMONG PATIENTS WITH DIABETES Beverly Mielke 1; Mark Perkins 2; Edwin Wong 2; Chuan-Fen Liu 3; David Au 4; Christopher Bryson2. 1UW Medicine, VA Puget Sound Healthcare System, Seattle, Washington ; 2VA Puget Sound Health Care System, Seattle, Washington ; 3Department of Veterans Affairs, Seattle, Washington .
(Tracking ID # 11022)
BACKGROUND: While there has been extensive research into patient specific predictors of adherence and patient specific interventions to improve adherence, little work has focused on organizational level factors that may either facilitate or hinder adherence. Pharmacists working in primary care clinics are an integral part of many patient-centered medical homes. We examined whether the presence of pharmacists in VA primary care clinics was associated with medication adherence among patients with diabetes. METHODS: We obtained refill data for all patients with diabetes on an oral medication seen in VA primary care clinics during fiscal years 2006 and 2007. We calculated a medication possession ratio using an algorithm developed specifically for the VA data sources, classifying patients as adherent if they had more than 80% of their oral therapy regimen during the first quarter of 2007. For all clinics with more than 100 such patients, we calculated an adjusted proportion of patients adherent in that clinic. Adjustment included patient level factors such as age, comorbidities, and diabetes severity from diagnostic codes. We then used organizational data from the VA Primary Care Survey,

which reported the number of full time equivalents (FTE) of pharmacists working within primary care. We used generalized estimating equations both to produce the adjusted proportions and to examine the association between pharmacy FTE per thousand patients with diabetes and proportion of adherent patients.
RESULTS: There were 212 clinics overall, comprised of 139 VA medical centers (VAMC) and 73 community-based outpatient clinics (CBOCs) in the sample, with a total of 304,472 patients represented. Overall, 71% of clinics had some pharmacist support, with 69% of VAMCs and 74% of CBOCs in the sample reporting support. There were 0.95 (range 07.6) pharmacist FTE per 10,000 clinic patients and 1.5 (0 to 14.4) pharmacist FTE per 100,000 patient-visits per year on average. The overall proportion of adherent patients was 70.8%, with wide clinic-level variation from 57.9% to 79.8% adherent patients. The adjusted proportion of patients adherent in clinics staffed with pharmacists (70.7%, 95% CI69.9% to 71.4%) and clinics without pharmacists (71.3%, 95% CI 70.1 to72.4%) was not different. Among all clinics, there was a small negative association between pharmacy FTE and adherence (0.27% per FTE, 95% CI 0.51 to 0.02%). In all other analyses after adjusting for the number of patients per clinic, or restricting to clinics with pharmacists, there were no significant associations between FTE and adherence.
CONCLUSION: This observational analysis of pharmacy FTE in primary care clinics did not explain the wide variation observed in clinic-level medication adherence. In addition to considering the usual threats to validity in cross-sectional observational data, other external organizational support, such as telephone wait times and administrative support to facilitate the mechanics of refills, may be more important in promoting adherence than high-level internal support such as pharmacists.
A RANDOMIZED CONTROLLED TRIAL OF PEER MENTORING AND FINANCIAL INCENTIVE TO IMPROVE GLUCOSE CONTROL IN AFRICAN AMERICAN VETERANS Judith A. Long 1; Erica Jahnle 2; Diane Richardson 1; Kevin Volpp1. 1Philadelphia VA Center for Health Equity Research and Promotion, Philadelphia, Pennsylvania; 2University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania. (Tracking ID # 11023)
BACKGROUND: Minority populations have disproportionately high rates of Diabetes Mellitus (DM), poor DM control, and the consequences of poor control micro-vascular complications. Interventions that improve DM control in minority population have the potential to reduce important health disparities. In this study we conducted a randomized controlled trial to test the effectiveness of peer mentoring and financial incentives in improving glucose control relative to usual care in a population of African American veterans.
METHODS: All participants were African America veterans, with persistently poor DM control (last 2 HbA1c readings >8%), between the ages of 50 and 70 years. Participants were randomized to one of three arms (usual care, peer mentoring, or financial incentives), with follow-up 6 months after enrollment. Participants had a study HbA1c drawn at enrollment and at follow-up. In addition they were called monthly to assess for hypoglycemic symptoms. Those in the peer mentoring arm were matched to a trained mentor who previously had poor DM control (HbA1c >8%) but now was in good control (HbA1c <8%). Mentors were called monthly to reinforce the training and given $20 a month for speaking with their mentee at least four times/month. Participants randomized to the financial incentive arm were told they could earn $100 at six months if their HbA1c dropped by one point and $200 if the HbA1c dropped by two points or to 6.5%. We used an intention to treat analysis and assumed no change from baseline in HbA1c for those lost to follow-up who did not have a current (+/1 month) HbA1c in the electronic medical record.
RESULTS: A total of 118 veterans were enrolled and randomized to the 3 arms (39 to usual care, 39 to peer mentoring, and 40 to financial). The mean baseline HbA1c by arm was: usual care 9.9 (SD1.6), peer mentoring 9.8 (SD 1.8), and financial incentive 9.5 (SD1.5). The mean baseline HbA1c for peer mentors (based on chart review that made them eligible for the study) was 6.7% (SD 0.6). Follow-up HbA1c was missing for 2 people in the usual care arm, 3 in the peer mentoring arm, and 4 in the financial arm. HbA1c dropped by 0.1% in the control arm, 0.9% in the peer mentoring arm, and 0.3% in the financial incentive arm. After adjusting for

baseline HbA1c, the mean change relative to control was 1.02 points (95% CI 1.75 to 0.29) in the peer mentoring arm and 0.53 points (95% CI 1.22 to 0.15) in the financial incentive arm. The intervention was well tolerated. Participants reported <3 minor hypoglycemic symptoms per month 91% of the time (511/563 calls). In addition, there were only two hospitalizations for hypoglycemia (1 in the control arm and 1 in the financial incentive arm). CONCLUSION: Peer mentors had a strong and statistically significant effect in improving glucose control in a population of veterans with persistently poor DM control whereas financial incentives had only a marginal influence on glucose control. Peer mentors may be a relatively low-cost and culturally sensitive means to improving glucose control and reducing racial disparities in diabetic outcomes.

RACIAL/ETHNIC DISPARITIES IN CANCER SCREENING RATES AMONG PATIENTS OF HEALTH CENTERS Quyen Ngo-Metzger 1; Ravi Sharma 1; Leiyu Shi 2; Seiji Hayashi 1; Charles Daly 1; Robert Politzer 3; Quyen Ngo-Metzger1. 1Health Resources and Services Administration, Rockville, Maryland ; 2Johns Hopkins School of Public Health, Baltimore, Maryland ; 3Consultant, Columbia, Maryland. (Tracking ID # 11025)

BACKGROUND: Certain racial/ethnic minority populations in the US have higher cancer prevalence and mortality, underscoring the need for

prevention and early detection. In order to rectify any disparities, evidence-based screening guidelines must be implemented effectively in minority communities.

Health Centers are Federally Qualified Health Centers supported by the Health Resources and Services Administration. They serve nearly 1 in 4 low-income (below 100% Federal Poverty Level) individuals in the US and 1 out of 7 uninsured Americans, many of whom are racial ethnic minorities. For patients of Health Centers, our objective is to assess the presence and magnitude of disparities among racial/ethnic groups and other key variables in the use of three types of cancer screening tests -Pap smear, mammogram, and colorectal screening (CRS), including sigmoidoscopy, colonoscopy, and home blood stool test - after accounting for confounding factors.

METHODS: Cross-sectional analyses using the 2009 Health Center Patient Survey. This face-to-face interview survey comprises a nationally-representative sample of 4,558 patients seen at a Health Center in the last 12 months including 1,278 non-Hispanic white, 1,142 African American, and 1,973 Hispanic patients. We estimated logistic regression models to predict the likelihood of obtaining each of three types of screening tests, after controlling for the following factors: the presence and source of health insurance coverage, presence and number of comorbidities, income relative to the Federal Poverty Level, employment status, self-reported health status, tobacco use, alcohol use, gender, age group, educational attainment, work disability or work limitation, and preferred language. RESULTS: Among health center patients, African Americans are as likely as non-Hispanic whites to receive all three types of screening (Pap, OR=1.54, 95%CI: 1.12, 2.12; Mammogram, OR=1.60, CI: 1.07, 2.40; CRS, OR=1.34, CI: 1.01, 1.77). For Pap smear and Mammogram use, there are no disparities evident between Hispanics and non-Hispanic whites (OR=1.41 (1.03, 1.95); OR=1.37 (0.93, 2.01) respectively). Regardless of race/ethnicity, smoking is strongly associated with lower likelihood of screening (Pap, OR=0.70 (0.54, 0.92); Mammogram, OR=0.51 (0.36, 0.73); CRS OR=0.79(0.62, 1.00). Additionally, lack of health insurance is strongly associated with lower likelihood of screening (Pap, OR=0.66 (0.52, 0.84); Mammogram, OR=0.54 (0.38, 0.75); CRS, OR=0.47 (0.37, 0.60).

CONCLUSION: Among Health Center patients, racial/ethnic minorities appear to be as likely as Whites to receive cancer screening, even after controlling for important clinical and demographic factors. Although smoking is a risk factor for cancer, in this study, smoking is associated with a decreased rate of cancer screening. We find that disparities due to health insurance exist: those who lack insurance coverage were less likely to be screened than those with coverage. These findings are consistent with other national data that show disparities due to lack of health insurance. Expansion of coverage may reduce disparities in cancer screening in

all settings. Furthermore, more research is needed to better understand the association between smoking and lack of cancer screening. Providers may need additional interventions to increase cancer screening among smokers.

A PERSONAL HEALTH RECORD MODULE IMPROVES DOCUMENTATION OF FAMILY HISTORY Jeffrey L. Schnipper 1; Lynn A. Volk 2; Jonathan S. Wald 3; Tejal K. Gandhi 2; Deborah H. Williams 1; Blackford Middleton2. 1Brigham and Womens Hospital, Boston, Massachusetts;
2Partners HealthCare System, Wellesley, Massachusetts; 3JSW, Inc., Sharon, Massachusetts. (Tracking ID # 11026)

BACKGROUND: Collecting and documenting detailed patient family history information is important to identify those at high risk for disease who may benefit from increased surveillance and/or risk factor modification. Currently, effective methods are lacking for systematically collecting and documenting this information for use in clinical decision support and patient care. This study evaluated the use of a family history module within an electronic personal health record (PHR) on the frequency and comprehensiveness of documented family history information. METHODS: We randomized 11 primary care practices within an integrated delivery system in the Northeast that used the Patient Gateway PHR. In the intervention practices, consented patients received access to an electronic Family History module three weeks before a scheduled office visit requesting detailed information on their personal and family history of six target conditions (breast and colon cancer, coronary artery disease, diabetes, glaucoma, and osteoporosis). Patients submitted eJournals that could be viewed by physicians during the visit where the information could be verified and easily added to the electronic health record (EHR). Study patients included those who submitted eJournals and had an associated visit. Control patients submitted eJournals about topics unrelated to family history. Study outcomes included mean number of conditions documented in the EHR per patient and mean quality score reflecting the comprehensiveness of the documented history. Scores for each condition were calculated by giving one point each for number of relatives, the degree of relationship, and the age of onset. Differences in documentation before and 30 days after the visit in the two arms of the study were analyzed using Wilcoxon rank sum test. RESULTS: 652 of 975 patients (66.9%) invited to complete a family history module submitted an eJournal. The mean number of conditions per patient documented in the EHR increased significantly more after the visit in the intervention arm compared to the control arm. The increase in quality score was greater in the intervention group, although the difference was not quite statistically significant. A weighted score which integrated quantity and quality of documented family history information also increased more in the intervention arm than in the control arm (Table).

CONCLUSION: An electronic PHR module requesting updated family history information from patients prior to an office visit was associated with a significant increase in the number of conditions documented in the EHR. There was also a trend towards more comprehensive information regarding number of relatives, degree of relationship, and age of onset for each condition, information crucial to determine patient risk and guide management.

HEALTH INFORMATION EXCHANGE AND QUALITY OF CARE Lisa Kern 1; Yolanda Barron 1; Rina Dhopeshwarkar 1; Rainu Kaushal1.
1Weill Cornell Medical College, New York, New York. (Tracking ID # 11027)

BACKGROUND: Health information exchange, or the electronic sharing of clinical data across health care providers, has become a national priority. However, evidence on the effectiveness of health information exchange has been limited. We previously found, in a cross-sectional study, that health information exchange was associated with higher ambulatory quality of care. However, it was not possible in that study to rule out confounding by physicians baseline quality of care. This study was designed to address that limitation. Our

objective was to determine any association between health information exchange and quality of care, adjusting for baseline quality of care.
METHODS: We conducted a longitudinal cohort study over two years (Clinicaltrials.gov Registration #NCT00225563). We included primary care physicians in the Taconic Independent Practice Association in the Hudson Valley region of New York State. We included all of those primary care physicians who had at least 150 patients with MVP Healthcare and had quality data at baseline and follow-up. All physicians had access to an electronic portal, through which physicians could view test results, radiology reports, discharge summaries and other reports for their patients over time, regardless of the ordering physician. We used usage of the portal as the independent variable. For the dependent variable, we used health care quality at follow-up, as measured by 13 metrics from the Health Plan Employer Data and Information Set (HEDIS) and 2 patient satisfaction metrics. We used generalized estimation equations to measure associations between usage and quality at follow-up, adjusting for 11 physician characteristics (including adoption of electronic health records, case mix, resource utilization and health care quality at baseline).
RESULTS: We included 138 primary care physicians. The mean practice size was 4 physicians per practice. Nearly half (43%) of the physicians were users of the portal. Non-users performed at or above average for 51% of the quality metrics at both baseline and follow-up (p=1.00). Users performed at or above average for 57% of the quality metrics at baseline and 64% at follow-up (p=0.06), a relative improvement of 12%. Adjusting for physician characteristics and baseline quality, use of the portal was independently associated with higher quality of care at follow up (Odds Ratio 1.42; 95% Confidence Interval 1.04, 1.95; p=0.03).
CONCLUSION: Health information exchange, which is presently being encouraged by federal incentives, was associated with modest improvements in ambulatory quality.
MEDICAL JOURNALS IN THE 21ST CENTURY: HOW CAN THEY REFLECT THE MANY FACES OF GENERALISM? Jocalyn Clark 1;
Jocalyn Clark2. 1Public Library of Science (PLoS), Toronto, Ontario;
2PLoS, Toronto, Ontario. (Tracking ID # 11028)
BACKGROUND: As a prime mode of dissemination for researchers and practitioners in general and internal medicine, medical journals aim to publish the best science and debate across all areas of medical education, research, policy, and practice. Individually and collectively, general medical journals strive to serve their diverse readerships by promoting quality research and reporting, medical professionalism, and the integrity of the scientific literature.
But what is the evolving role of general medical journals in the 21st century? Beyond being venues for the publication of science, journals like Journal of General Internal Medicine (JGIM), BMJ, PLoS Medicine and the other leading general medical journals are now interestedand often requiredto engage in broader activities that help improve the world in which we all practice and teach. These responsibilities include arbitrating plagiarism, authorship, competing interests, and other editorial crimes and misdemeanours (JGIM Jan 2011: p1); intervening when necessary in allegations of research misconduct; promoting best publication practice and ethics; organizing as groups of editors to set standards on trial registration and interactions with the pharmaceutical industry; and advocating for social responsibility and the health of vulnerable populations.
METHODS: In this session, Dr Jocalyn Clarksenior editor at PLoS Medicine, former assistant and associate editor at BMJ, assistant professor of medicine at the University of Toronto, member of SGIM, and member of the editorial policy committee of the World Association of Medical Editors (WAME)will report 3 recent cases that reflect the new roles and responsibilities of medical journals. She will discuss the leadership agenda needed to address the challenges and external pressures that both journals and the profession face, and how GIM practitioners can shape and influence that agenda. Evidence shows that none of these cases was simple or straightforwardbut each case provides an opportunity to reflect and debate the role of journals within the broader world of general and internal medicine.

RESULTS: Ghostwriting. Publishing ethics say that ghostwriting is unethical and unacceptable; but it is pervasive in the medical literature. The astonishing extent of ghostwriting in the HRT literature was revealed recently when PLoS Medicine &The New York Times partnered to intervene in litigation that resulted in the public release of 1000 s of documents showing how HRT was over-promoted by Wyeth and the risks to womens health downplayed. How can journals fight against ghostwriting and what can GIM profession do to help? Editors Competing Interests. Recent published research has revealed the extent of income from advertisements, reprints, and industry-supported supplements received by leading general medical journals, raising questions about the competing interests of editors. Given that most journals have concerned themselves mostly with the competing interests of authors and reviewers, what are the ways that journals can examine and manage their own potential for conflict? Journals Social Responsibility. If medical journals are to reflect the stated social responsibility commitments of professional associations like SGIM, they must orient their journal scope and priorities to address the needs of vulnerable populations. PLoS Medicine recently undertook an extensive re-visioning of its scope to reflect the global burden of disease and to prioritize papers addressing global health issues. How do general medical journals promote social responsibility, and how can GIM practitioners influence this aspect of journals?
CONCLUSION: The many faces of generalism demand that general medical journals in the 21st century assume new and evolving leadership roles to reflect the diversity of GIM and the external pressures that professionals and journals face. Continued debate and collaboration are required.

PERCEPTIONS OF RATES OF UNINTENDED PREGNANCY AMONG PRIMARY CARE PROVIDERS Eleanor Bimla Schwarz 1; Eleanor Bimla Schwarz 1; Sara M. Parisi 1; Mindy Sobota 2; Melissa Nothnagle 3; Cynthia Chuang4. 1University of Pittsburgh, Pittsburgh, Pennsylvania ;
2Oregon Health Sciences University, Portland, Oregon ; 3Brown University/Memorial Hospital of Rhode Island, Pawtucket, Rhode Island ;
4Penn State College of Medicine/Milton S. Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 11029)
BACKGROUND: Primary care providers (PCPs) treat many women of reproductive age and are well positioned to address risk of unintended pregnancy. As contraceptive effectiveness is a major factor in womens contraceptive decision making, it is important for PCPs to convey accurate information on the risk of unintended pregnancy with and without available methods of contraception.
METHODS: We distributed an online survey to 550 PCPs trained in General Internal Medicine or Family Medicine and practicing in Western Pennsylvania, Central Pennsylvania, Rhode Island, or Oregon, in 2009. The survey focused on PCPs experiences using electronic medical records and clinical decision support. In addition, the survey contained 6 open-ended questions to assess their knowledge of the prevalence of unintended pregnancy in the United States, risk of pregnancy among non-users of contraception, and the failure rates of available contraceptive methods with typical use. Responses were considered to be correct if they were within two percentage points above or below the typical use failure rates provided by the 19th edition of Contraceptive Technology: for condoms (15%), oral contraceptive pills (8%), contraceptive injections (3%), and IUDs (< 1%). Similarly, estimates of the prevalence of unintended pregnancy in the US were considered correct if they ranged from 48-52%, and estimates of the risk of pregnancy with use of no contraception were considered correct if they were between 83-87%.
RESULTS: One hundred and seventy-two PCPs completed the online survey, a response rate of 31%. The majority (54%) of respondents underestimated the prevalence of unintended pregnancy in the US and 81% underestimated the risk of pregnancy among women using no contraception. On average, those that underestimated the prevalence of unintended pregnancy underestimated it by 23+/8 percentage points. Those that underestimated the risk of pregnancy among women using no contraception underestimated it by a mean

of 35+/20 percentage points. The majority of PCPs also underestimated the typical use failure rate of most contraceptive methods, with the exception of the IUD. Specifically, 86% of PCPs underestimated the typical use failure rate of oral contraceptive pills, 62% underestimated the typical use failure rate of condoms, and 16% underestimated the typical use failure rate of contraceptive injections. Although the majority of PCPs correctly reported the failure rate of IUDs as <1%, they were more likely to overestimate the failure rate of IUDs than any other contraceptive. Male PCPs were significantly more likely to underestimate the prevalence of unintended pregnancy than were female PCPs (70% vs. 42%, p=0.001). But male and female PCPs were equally likely to underestimate the risk of pregnancy among women using no form of contraception (80% males vs. 83% females, p=0.53).
CONCLUSION: Many PCPs have inaccurate perceptions of rates of unintended pregnancy with typical use of available contraceptives, and many underestimate the risk of pregnancy when no contraception is used. Whether more accurate perceptions of rates of unintended pregnancy would improve PCPs provision of preconception and contraceptive counseling is unknown, but deserves further study.
REDUCING DISPARITIES IN ACCESSING PRIMARY CARE: THE ROLE OF HEALTH CENTERS Quyen Ngo-Metzger 1; Leiyu Shi 2; Seiji Hayashi 1; Charles Daly 1; Ravi Sharma 1; Robert Politzer3. 1Health Resources and Services Administration, Rockville, Maryland ; 2Johns Hopkins School of Public Health, Baltimore, Maryland ; 3Consultant, Columbia, Maryland. (Tracking ID # 11030)
BACKGROUND: Disparities in access to primary care in different types of health care settings are found to be due to race/ethnicity, health insurance, income, and health needs. The purpose of this study is to examine the experience of primary care by patients seen at health centers (HCs) compared to mainstream healthcare settings such as physician offices (POs) HMOs, and hospital outpatients (HOs). The focus is on racial/ethnic (predisposing), health insurance, income (enabling) and health (need) disparities, and the role of the healthcare system in overcoming these.
METHODS: Comparative effectiveness study based on cross-sectional analyses of two nationally representative surveys. For patients seen at HCs, the 2009 Health Center Patient Survey was used. The survey, sponsored by the Health Resources and Services Administration, has a probability sample of 4,562 patients representing over 13 million HC medical patients seen during 2008. For patients seen at other healthcare settings, the 2008 National Health Interview Survey was used. To reflect the design of the Health Center Patient Survey, only respondents with at least one physician visit in mainstream healthcare settings (n=21,545) were included. Similar measures of primary care accessibility (e.g., usual source of care USC, unable or delayed in getting medical care, unable to get dental care, unable to get mental care, unable to get prescription drugs) were used in both analyses. In addition to race, income, insurance, and health status, other covariates in the multivariate analyses were age, gender, education, marital status, employment, disability, and residential region.
RESULTS: Patients seen at HCs experienced comparable or better accessibility to primary care compared to other settings, e.g., 96% of HC patients identified a USC compared to 85% for patients nationally. Whereas there were no racial/ethnic and health-status related disparities and limited insurance-related disparities in HC settings, significant disparities (racial/ethnic, insurance, and income) existed in other settings. For example, in terms of racial/ethnic disparities, nationally 17% African Americans and 29% Hispanics did not have a USC, compared to 12% whites (p<.01). 12% African Americans and 11% Hispanics were unable to get needed medical care compared to 8% whites (p<.01). Nationally 49% uninsured did not have a USC, compared to 9% privately-insured (p<.01). 27% uninsured were unable to get needed medical care compared to 4% privately-insured (p<.01). In terms of income disparities, nationally 24% low-income patients did not have a USC, compared to 10% higher-income patients (p<.01). 15% low-income patients were unable to get needed medical care compared to 4% higher-income patients (p<.01). These national-level disparities (two-fold for racial/ethnic groups and three-plus-fold for insurance and income groups) persisted after controlling for other patient

sociodemographic characteristics.
CONCLUSION: Patients seen at HCs report comparable or better accessibility to primary care compared to other healthcare settings. Unlike other healthcare settings where significant disparities existed in primary care quality among patients with different racial/ethnic, insurance, and income groups, few disparities were noted among HC patients. As safety-net providers for uninsured and vulnerable populations, HCs provide high-level accessibility to primary care and overcome health disparities.

ASSOCIATION OF EDUCATIONAL DEBT WITH QUALITY OF LIFE, BURNOUT, AND MEDICAL KNOWLEDGE: A NATIONAL STUDY OF INTERNAL MEDICINE RESIDENTS Colin P. West 1; Tait D. Shanafelt 1; Joseph C. Kolars2. 1Mayo Clinic, Rochester, Minnesota; 2University of Michigan Medical School, Ann Arbor, Michigan. (Tracking ID # 11031)
BACKGROUND: Physician debt has steadily increased in recent years, and the median debt of the medical school graduating class of 2010 was $160,000. Increased educational debt has been associated with decreased career satisfaction, depressive symptoms, and cynicism among care providers. However, despite the established prevalence of distress in medical students and physicians, there are no data on the relationship between debt and other specific aspects of well-being such as burnout or quality of life (QOL). Associations with competency have also not been explored.
METHODS: We conducted a study of United States residents using the 2008 Internal Medicine In-Training Examination (IM-ITE) survey. Educational debt was assessed, along with quality of life (QOL) and symptoms of burnout. Medical knowledge was measured by scores on the IM-ITE. Associations between debt, well-being factors, and medical knowledge were analyzed in multivariable models.
RESULTS: Data were obtained for 16,394 residents, representing 74.1% of all eligible U.S. internal medicine residents in the 20082009 academic year. QOL exhibited little association with debt. However, the presence of at least one symptom of burnout was more common among residents with greater amounts of educational debt (odds ratio, 1.72 [CI 1.49 to 1.99]; $p<0.001$ for debt >$200,000 relative to no debt). IM-ITE scores were lower at higher debt levels, with a difference of 5.0 points between residents with no debt and residents with debt exceeding $200,000. This difference exceeded the 4.1-point and 2.7-point differences seen as residents progressed through their first and second years of training, respectively. CONCLUSION: Debt burdens were associated with increased symptoms of burnout and lower medical knowledge scores. These associations with well-being and a key training competency have not previously been reported, and emphasize the potential for debt to impact both physician well-being and patient care skills. Further study of the effects of debt on physicians is warranted.
TREATMENT WITH DALTEPARIN IS ASSOCIATED WITH LOWER RISK OF BLEEDING COMPARED TO TREATMENT WITH UNFRACTIONATED HEPARIN, IN PATIENTS WITH CHRONIC KIDNEY DISEASE Manuela Calvo 1; Manuela Calvo 1; William Southern2. 1Albert Einstein College of Medicine, Bronx, New York; 2Albert Einstein College of Medicine, Sleepy Hollow, New York. (Tracking ID # 11033)
BACKGROUND: Subcutaneously administered low-molecular-weight heparins (LMWH) have emerged as the drugs of choice for hospitalized patients requiring anticoagulation because of their favorable safety profile and ease of use. However, because LMWHs are excreted by the kidneys, and accumulate in patients with chronic kidney disease (CKD), intravenous infusion of unfractionated heparin (UFH) is often used in patients with CKD. We sought to examine the safety of using Dalteparin, a LMWH that has shown minimal tendency to accumulate, in patients with CKD. We hypothesized that any risk associated with accumulation of Dalteparin would be offset by the risks of intravenous infusion of UFH, which requires more frequent monitoring and adjustment of dosing. We therefore compared the risks of bleeding in patients with CKD who are treated with Dalteparin vs. UFH.

METHODS: In this retrospective cohort study we examined all patients with CKD (GFR <60), admitted to the medical service of an urban academic medical center from January 1, 2006 to June 30, 2010 who were treated with treatment doses of Dalteparin or UFH. Treatment
doses were defined as 10000 units of daily for a minimum of three days for Dalteparin and intravenous infusion for a minimum of three days with at least one activated partial thromboplatin time 50 seconds for UFH. Smaller doses were thought likely to be used for prophylaxis, and were excluded. Demographic characteristics, laboratory values, ICD-9 code diagnoses, and inpatient medications were extracted for each admission from the electronic medical record. The primary outcome was bleeding, defined as an ICD-9 code for any bleeding event within 60 days of the initiation of anticoagulant therapy. Patients treated with dalteparin vs. UFH were compared with respect to demographic characteristics, length of stay, admitting diagnosis, co-morbidities, history of bleeding, treatment with warfarin, laboratory values (creatinine, liver function tests, hemoglobin, platelet count, INR, aPTT) and bleeding rates using t-tests and chi-squared tests, as appropriate. We constructed logistic regression models to examine the independent association between choice of anticoagulant (Dalteparin vs. UFH) and bleeding rates, after adjustment for demographic and clinical characteristics of patients.
RESULTS: Of 3546 patients with CKD treated with anticoagulants, 2045 (58%) received Dalteparin and 1501 (42%) received UFH. Patients treated with dalteparin were older, and had fewer comorbidities. A total of 355 bleeding events were identified .The incidence of bleeding was 7.6% in the dalteparin group vs. 11.7% in the UFH group (p<0.001). After adjustment for demographic and clinical characteristics, treatment with dalteparin was associated with significantly smaller risk of bleeding (OR 0.69, 95% CI:0.55-0.88) when compared with treatment with UFH.
CONCLUSION: The use of dalteparin in patients with renal insufficiency was associated with a lower rate of bleeding events compared to the use of UFH in a group of patients with similar characteristics. Dalteparin appears to be safe to use in patients with CKD.
RESEARCH WITHOUT RESULTS: INADEQUATE PUBLIC REPORTING OF CLINICALTRIAL RESULTS Ravi K. Gopal 1; Traci E. Yamashita 2; AllanV. Prochazka1. 1Denver VAMC, Denver, Colorado; 2University of Colorado Denver Health Science Center, Aurora, Colorado. (Tracking ID # 11035)
BACKGROUND: With a goal to increase transparency of the medical literature, required registration of randomized trials began in 1997. The online database clinicaltrials.gov launched in 2000 to meet these requirements. The Food and Drug Administration Amendment Act (FDAAA 801) of 2007 requires basic results reporting starting in September 2008. This law mandates that the study sponsor or principal investigator submit results no later than 1 year after primary completion date, but may be extended for 1 year upon request under good cause. We aimed to evaluate the rate of compliance with results reporting by applicable trials registered inclinicaltrials.gov and the peer-reviewed publication rate for completed studies with results. METHODS: From all 99,315 records in clinicaltrials.gov, we excluded not applicable studies per FDAAA 801 (without a United States site, phase 0 and 1, non-interventional studies), then grouped records by primary completion date into the year before required reporting, October 2006 to September 2007 (0607), and one and two years after required reporting of results, October 2007 to September 2008(0708) and October 2008 to September 2009 (0809). Abstracted data from the records included presence of results in clinicaltrials.gov, funding source, trial phase, enrollment size, and publication listed in clinical trials.gov or found in pubmed.gov by searching for clinical trials registration number. The primary and secondary outcomes were the rate of results reported in clinicaltrials.gov and publication rate among studies reporting results. Bivariate comparisons between the outcomes with funding and phase were tested with the chi-squared statistic. Mean number of subjects enrolled was compared using the t-test. Logistic

regression models were determined using stepwise selection from all study characteristics. Number enrolled was mean-centered and transformed to represent a unit change of 100 subjects.

RESULTS: We identified 1097 records in 0607, 2231 in 0708, and 2923 in 0809. Study characteristics did not differ over the study period including funding source, study phase, and number subjects enrolled. Results reporting increased from 6.8% (n=75) prior to mandatory reporting to 19.7% (n=427, p<.001) in 0708 and 10.8% (n=316, p<.001) in 0809. In regression analysis, odds ratios for reporting results was 3.34 (95%CI: 2.56-4.35) for 0708 and 1.75 (95% CI: 1.34-2.30) for 0809, versus 0607. Industry funding had positive association with reporting (OR1.60, 95%CI: 1.14-2.25) while NIH funding (OR .60, 95%CI: .42-.87) and other U.S government funding (OR .19, 95%CI: .06-.63) were negatively associated. Focusing on the 818 records that had results in clinictrials. gov, 60% (n=45) in the year prior to mandatory reporting had a peer reviewed published paper that could be found in clinicaltrials.gov or pubmed.gov. This rate decreased to 32.8% (n=140, p<.001) in 07 08 year and further to 19.9% (n=63, p<.001) in the 0809 year. In regression analysis, the odds of records with peer-reviewed published results decreased after required reporting (0708 OR: .31, 95%CI .19-.53; 0809 OR: .16, 95%CI .09-.28). Studies that were NIH funded (OR3.55, 95%CI: 2.08-6.06), Phase III (OR 2.56, 95%CI: 1.82-3.60), and larger enrollment (OR 1.02, 95%CI 1.01-1.04) were more likely to publish their results. A total of 1,112,461 subjects were enrolled in studies over the study period in which no results were reported.
CONCLUSION: Clinical trial registry has increased the transparency of published trials, but this represents a small minority of trials. Reporting of basic results for all applicable registered trials has increased but not reached its goal of universal reporting, with industry funded studies leading the way. Unfortunately, patients are still being left on the cutting room floor. Enticements with either a stick or carrot and barriers to reporting need to be identified to improve data reporting and hence transparency.

EFFICACY OF ELECTRONIC TOOLS TO ASSIST WITH IDENTIFICATION OF AND COUNSELING FOR OVERWEIGHT PATIENTS Joyce Tang 1; Robert F. Kushner 1; David W. Baker1. 1Northwestern University, Chicago, Illinois. (Tracking ID # 11040)

BACKGROUND: Although overweight (Body Mass Index [BMI] 2529.9 kg/m2) is associated with serious health consequences, physicians often do not recognize patients who are overweight and infrequently counsel them about weight loss. Our objective was to evaluate a set of electronic health record (EHR)-embedded tools to assist with identification and counseling of overweight patients.

METHODS: Physicians at an academic GIM clinic were randomized to activation of an EHR-embedded tool set (n=15) or to serve as usual care controls (n=15). The tool set included: automated calculation of BMI; physician point-of-care alert for overweight (BMI 2729. 9 kg/m2); a counseling template to help physicians counsel patients on action plans; and an order set to facilitate entry of overweight as a diagnosis and order relevant patient handouts. We queried the EHR weekly to obtain names of patients for whom the tool set was used. These patients were surveyed by phone 3 weeks after their appointment and queried about progress toward their goal and perspectives about counseling received. Medical records were reviewed for a random sample of patients with BMI 2729.9 kg/m2 who had a visit with an intervention group physician (n=100) or with a control group physician (n=100) during the study period in order to assess physician recognition of overweight as a problem (i.e. listed as an encounter diagnosis or problem in the assessment and plan) and documentation of weight-specific counseling (i.e. recommendation for weight loss or maintenance). Outcomes for intervention and control groups were compared using chi
square tests. Intervention physicians also completed an anonymous survey rating the tools and ranking barriers to tool use.

RESULTS: Intervention group physicians were more likely than control physicians to document a diagnosis of overweight (28% vs. 8%, respectively; p<0.001) and to document weight-specific counseling (32% vs. 18%, respectively; p=0.02). Two-thirds of intervention physicians documented counseling in at least 20% of their overweight patients, but only 36% of control physicians did. When documenting weight-specific counseling, intervention group physicians used the tool about half the time. Overall, the tool was used in response to only 10.7% of alerts, but 5 physicians used the tool in response to 2040% of prompts. When the tool was used,

physicians nearly always entered overweight as an encounter diagnosis (97%) and documented an action plan (98%). Sixty-one patients for whom the tool was used were interviewed by phone 3 weeks after their visit (63% response rate). Virtually all patients reported taking steps toward their goal (98%), and most said counseling increased their motivation (93%) and led to changes in their diet or exercise habits (88%). Most intervention physicians responding to a survey (73% response rate) agreed that the tool alerted them to patients they did not realize were overweight (91%) and improved the effectiveness of their counseling (82%). Physicians estimated the tool required 7.5 minutes to use, and rated time as the most important barrier to tool use.
CONCLUSION: EHR-based alerts and management tools increased documentation of overweight, the frequency of counseling, and short-term behavior change among the vast majority of patients for whom the tools were used. Although a subgroup of physicians used the tools frequently, overall tool usage was low due to time constraints. Future efforts to increase physician counseling need to identify ways of overcoming the time constraints of a routine office visit.
FACTORS AFFECTING LEARNERS DAILY PRIORITIES DURING WARD ATTENDING ROUNDS AND ATTENDING PHYSICIANS ADAPTABILITY Brita Roy 1; Nidhi Huff 2; Analia Castiglioni 1; Lisa Willett 1; Carlos Estrada 3; Robert Centor1. 1University of Alabama at Birmingham, Birmingham, Alabama ; 2University of Alabama at Birmingham, Birmingham, Alabama ; 3Birmingham VAMC, The University of Alabama at Birmingham, Birmingham, Alabama. (Tracking ID # 11041)
BACKGROUND: Understanding learners expectations and priorities for ward rounds is essential to enhance learning. In prior work, we identified domains necessary for successful ward rounds from the learners perspective. However, learners may prioritize domains differently due to daily changes in competing demands. This study aims to assess factors that affect the relative importance of each domain to learners on a daily basis and the frequency that attending physicians focus on those domains.
METHODS: In a prospective observational study, trainees from 39 different internal medicine inpatient ward teams at 3 hospitals from September-November 2010 independently completed daily evaluation cards. Each day, trainees (a) documented their teams total patient census (<5, 610, and >11 patients), (b) day of call cycle (pre-call, call, post-call, and other), (c) ranked the 2 domains their attending demonstrated best, and (d) selected the domain that was most important. Domains of successful ward rounds have been previously described, and included: Teaching Process(i.e. sharing decision-making process, physical exam skills), Learning Environment (i.e. being approachable, respectful), Role Modeling (i.e. teaching by example, bedside manner), and Team Management (i.e. efficiency, providing autonomy). Patients were admitted only on call days, every fourth night, maximum of 10 admissions in a 24-hour period; at least 1 trainee completed a 30-hour shift on the post-call day. We used Chi square tests to evaluate associations between census/call cycle and domain selected (Chi for trend).

RESULTS: Trainees completed 831 cards, evaluating 41 attendings. Team Management was the most important domain for learners on post-call days (40%) compared to non-post-call days (NPCD) (22%) (p<0.001), and attendings were ranked highly in Team Management on post-call days (ranked as a top attribute on 51% of post-call days, vs. 38% of NPCD; p=0.002). As patient census increased, Team Management was increasingly important to trainees (p-trend <0.001), but was not ranked as a top domain for attending performance (p-trend=0.56).
Teaching Process was most important on NPCD (29%) compared to post-call days (19%) (p=0.007), and attendings performed well in this domain on NPCD (59%) vs. post-call days (51%) (p=0.07). Teaching Process had no association with importance (p-trend=0.36) or performance (p-trend=0.56) as patient census increased. The importance of Role Modeling and Learning Environment was unchanged between post-call and NPCD days

(p=0.05, p=0.53; respectively). As patient census increased, Role Modeling became less important (p-trend=0.07), but attending physicians performed better in this domain (p-trend=0.04). Attending performance in Learning Environment decreased as patient census increased (p-trend=0.001), and it was a lower priority for learners (p-trend=0.02).
CONCLUSION: On post-call days and days with higher patient loads, efficiency and autonomy is the priority for trainees, but on other days attendings should focus on sharing decision making process. Success on ward rounds requires emphasis of different skills on different days: the best ward attendings recognize trainee fatigue and work load, and apply a diverse and adaptable skill set for changing needs.
CHRONIC CANCER MEDICATION ADHERENCE IN BREAST CANCER SURVIVORS: A QUALITATIVE STUDY Jenny J Lin 1; Helen-Maria Lekas 2; Liliana Serrano 3; Nina Bickell1. 1Mount Sinai School of Medicine, New York, New York ; 2Columbia University, Mailman School of Public Health, New York, New York ; 3Mount Sinai Medical Center, New York, New York. (Tracking ID # 11043)
BACKGROUND: Adherence to chronic medication is challenging but critical. As more primary cancer treatments are delivered orally and are under the patients control, understanding factors motivating cancer treatment adherence grows in importance. For women with breast cancer estrogen receptor-positive (ER+) tumors, primary adjuvant therapy requires five years of a daily anti-hormonal agent. While nonadherence tends to be higher among those experiencing side effects or with more negative views of anti-hormonal medications, other women with similar side effect profiles continue to adhere. We undertook this study to identify breast cancer survivors perceptions about and experience with hormonal therapy to inform an intervention to improve adherence.
METHODS: To date, we conducted 3 (2 English, 1 Spanish) of 6 focus groups with women diagnosed with early-stage ER + breast cancer for whom hormonal therapy was prescribed. We assessed their medication adherence, explored their beliefs about medication risks and benefits, medication side effects and barriers and facilitating factors to treatment adherence. We asked about quality of life issues, support needs, and psychosocial issues such as the symbolic meanings of continued cancer medication use (e.g., a perpetuation of the patient role). Each groups discussion was taped, transcribed verbatim and thematically analyzed.
RESULTS: We identified 4 major themes associated with medication adherence: (1) resilience exemplified by the ability to endure and cope with both medication side effects and cancer diagnosis; (2) belief that hormonal therapy is a preventive measure to decrease risk for recurrence (rather than ongoing treatment for breast cancer); (3) trust of physicians and the medical communitys knowledge; and (4) ability to exercise control over the uncertainty associated with cancer and its recurrence. Personal resilience in being able to cope with a cancer diagnosis and endure medication side effects was very
important (I consider myself a trooper). Patients almost universally felt that daily hormonal therapy helped prevent recurrence of breast cancer, although there was some difference in perceptions of how much risk reduction the medications afforded. Some felt that though the risk reduction may be very, very small, they continue to adhere for that 2% reduction in risk. Trust in
theirpersonalphysiciansandintheknowledgeofthemedicalsystemwasakey factor to continued adherence (I trust my oncologist implicitly). Women also felt that taking hormonal therapy was a personal choice (you choose to treat yourself and its up to you to find out all the best options). Some barriers to medication adherence included a misunderstandingof why oneneeded to take
themedication,poortrustoforcommunicationwithphysicians(e.g.notfeeling comfortable discussing side effects), worry about risks associated with medication and concerns about becoming dependent on medication.
CONCLUSION: Factors affecting breast cancer patients adherence to cancer medication are similar to other chronic diseases such as physician trust, physician-patient communication and beliefs about risks and benefits of medications. However, breast cancer patients also express issues of resilience, ability to endure medication side effects and risk of cancer recurrence as important aspects to medication adherence. As cancer survivors

live longer and more primary care physicians manage these patients and their chronic issues, it is important to recognize and support the factors that facilitate better medication adherence in these patients.

FACILITY CHARACTERISTICS DO NOT EXPLAIN HIGHER DIAGNOSTIC MAMMOGRAPHY FALSE POSITIVE RATES AT FACILITIES SERVING VULNERABLE WOMEN L. Elizabeth Goldman 1; Rod Walker 2; DianaL. Miglioretti 2; Rebecca Smith-Bindman 3; Karla Kerlikowske1. 1University of California San Francisco, San Francisco, California ; 2Group Health Research Institute, Seattle, Washington ; 3Univerisity of California San Francisco, San Francisco, California. (Tracking ID # 11044)

BACKGROUND: Facilities serving vulnerable women have higher diagnostic mammography false positive rates than facilities that serve primarily non-vulnerable women. False positives can lead to anxiety, unnecessary biopsies, and contribute to additional healthcare costs. Whether facility characteristics such as the availability of on-site breast ultrasound or biopsy, affiliation with an academic service, or profit status explain these differences in quality is unknown.

METHODS: We examined 78733 diagnostic mammograms obtained to evaluate a breast problem performed at Breast Cancer Surveillance Consortium facilities from 19992005. We used hierarchical logistic regression to determine if adjusting for facility characteristics accounts for differences in false positive rates between facilities serving vulnerable and non-vulnerable women. Facilities were assigned vulnerability indices according to the proportion of mammograms performed on women with lower educational attainment, racial/ethnic minority status, limited household income, or rural residence.

RESULTS: Higher false positive rates for diagnostic mammography interpretations to evaluate a breast problem at facilities serving vulnerable women were not explained by facility characteristics. While both availability of ultrasound and biopsy services onsite were associated with greater odds of a false positive in 7 of 8 models ($p<0.05$; ORs ranging from 1.24 to 1.88), adjustment for the availability of these services did not attenuate the association between vulnerability and false-positive rates. Prior to adjustment, odds ratios comparing the odds of a false positive between facilities on the basis of the binary vulnerability indices were: lower educational attainment (OR 1.33; 95% CI 1.03, 1.74); racial/ethnic minority status (OR1.33; 95% CI 0.98, 1.80); limited household income (OR 1.56; 95% CI 1.26,1.92); rural residence (OR 1.38; 95% CI 1.10, 1.73). After adjustment, these estimates were practically unchanged.

CONCLUSION: Availability of on-site diagnostic services may contribute to higher utilization of medical care overall, but it does not explain the higher

false-positive rates of diagnostic mammography at facilities serving vulnerable women. Future studies of diagnostic mammography interpretations should evaluate whether higher false positives rates at facilities serving vulnerable women are driven by radiologists concerns of a high cancer prevalence and low likelihood of follow-up in their patient populations.

ANTICOAGULATION OUTCOMES IN ATRIAL FIBRILLATION: IMPACT OF MENTAL ILLNESS Susan M. Frayne 1; Minang Turakhia 1; Rudolf Moos 1; Sarah A. Friedman 1; Susan Schmitt 1; Dan Berlowitz 2; Ciaran Phibbs1. 1VA Palo Alto Health Care System, Menlo Park, California; 2VA Bedford, Bedford, Massachusetts. (Tracking ID # 11045)

BACKGROUND: Warfarin anticoagulation can reduce stroke risk in atrial fibrillation (AF), but can harm patients with difficulty adhering to its rigorous monitoring requirements and complex dosing regimen. While clinicians often perceive patients with mental health conditions (MHC) as being at risk for non-adherence, little empiric evidence guides anticoagulation clinical decision-making in this population. We examined whether presence of comorbid MHC is associated with adverse anticoagulation outcomes: stroke, major hemorrhage, or death.

METHODS: Using the Veterans Health Administration (VA) National Patient Care Database linked to Medicare data, we identified 77,431 non-institutionalized patients with AF at the start of the observation period (FY2004) receiving warfarin from VA. We considered patients to have MHC Yes if they had an MHC ICD9 code (derived

from AHRQ Clinical Classifications Software algorithm) both at baseline and in the observation period. Patients were MHC No if they had no MHC ICD9 code in FY02-FY04. The 12,701 with ambiguous MHC status (ICD9 code at baseline or in the
observation period, but not both) were excluded from main analyses, leaving N=64,730 in the main analytic cohort. The primary outcome was the composite of stroke, major hemorrhage and death. Admissions for strokes and major hemorrhage were identified from ICD9 codes in inpatient VA and Medicare records, using established algorithms. Death was identified from VA Vital Status file (derived from VA and non-VA sources). Logistic regressions estimated adjusted odds ratios of MHC on the primary outcome and on its components, first controlling for age (AOR1), then also controlling for sex, race/ethnicity and CHADS2 stroke risk index (AOR2). RESULTS: Comparing the 10,731 MHC Yes versus the 53,999 MHC No, mean (SD) age was 72 (9.8) versus 75 (7.7) and mean (SD) CHADS2 was 3.0(1.5) versus 2.9 (1.5). 20.4% versus 16.0% had the primary (composite) outcome, 5.1% versus 4.3% died in FY04, 2.4% versus 1.3% had a stroke, and 14.4% versus 11.4% had a major hemorrhage. Patients with MHC Yes were more likely than those with MHC No to have the composite outcome in unadjusted and adjusted analyses (Table). This was true for each specific MHC as well; those with psychotic disorders and alcohol use disorders did particularly poorly. Examining components of the composite outcome, for stroke, AOR2 was 1.41; for hemorrhage, AOR2 was 1.27; and for death, AOR2 was 1.18 ($p<.05$ for each AOR2).
CONCLUSION: Warfarin-treated AF patients with MHC had significantly higher risk of stroke, hemorrhage, and death, even after adjustment for covariates. This effect was most pronounced for patients with psychotic or alcohol use disorders, pointing to the possibility that these represent high-risk subgroups. Identification of mediators of this relationship could inform efforts to improve AF-related outcomes in this vulnerable population, such as intensifying oversight of warfarin treatment or evaluating safety and efficacy of alternative stroke prevention therapies.
Table: Odds ratios for Primary Outcome, MHC Yes (and specific MHCs) versus MHC No
P <.05 for every odds ratio in table*AOR1, adjusted for age; **AOR2, adjusted for age, sex,
SYNDROMIC SURVEILLANCE OF INFLUENZA-LIKE-ILLNESS USING AUTOMATED VA DATA - PRELIMINARY RESULTS FROM THE IDAHO INFECTIOUS DISEASE REPORTING NETWORK William G Weppner 1;
Andrew Wilper 1; Joanne Mitten 2; Jay Tiumalu 3; Rick Tivis 3; Dennis Stevens4. 1Univ. of Washington/Boise VAMC, Boise, Idaho ; 2Boise VAMC, Boise, Idaho ; 3Idaho State University, Boise, Idaho ; 4Boise VAMC, University of Washington, Boise, Idaho. (Tracking ID # 11056)
BACKGROUND: Syndromic surveillance of disease uses existing health care information to help better identify and predict clinically relevant outbreaks of disease such as influenza. Currently, influenza-like illness(ILI) disease monitoring in Idaho is based on laboratory data combined with periodic person-to-person reports collected by Idaho state workers. This is time consuming an relies on voluntary reporting. Our objective was to study whether syndromic surveillance of ILI using data from the Veterans Administration electronic medical record (CPRS) correlates to officially reported influenza activity levels in the State of Idaho. METHODS: The Boise Veterans Affairs Medical Center (VAMC) provides care to over 20,000 veterans living in Idaho with clinics in Boise and surrounding sites. Using data from the Veterans Integrated Service Network (VISN 20) data warehouse for influenza from 2009, we identified ILI cases from these clinics using ICD-9 codes collected as weekly counts. Additional counts of fever (>100.5F) hypoxia (O2 <92%), lab tests for
influenza (A/B antigen, culture; novel flu), and prescriptions for antivirals (oseltamivir) were summed individually, and in an unweighted fashion as total weekly counts; Spearman correlation and multivariate logistic regression were used with predictors from the same week &preceding week. This was correlated with weekly flu activity as reported by the CDC; this reports geographic spread of influenza, as reported by state epidemiologists. The VA Puget Sound IRB approved this study. RESULTS: Using comparisons with epidemiologist-reported flu activity

level, all clinical data elements had statistically significant associations using Spearman correlation: sum of total counts of predictors r=0.57 (p<0.0001); lab tests r=0.51 (0.0001); ICD-9 codes r=0.47 (p=0.0003); prescription r=0.38 (p=0.005); fever r=0.31 (p=0.02); hypoxia r=0.28 (p=0.04). Total counts accounted for one-third (r2=0.3) of variance. Similar results were found for preceding week counts. In logistic regression, both ICD-9 and lab counts were significant predictors (Wald 2=6.80, p=0.009, Wald 2=7.15, p=0.007 respectively). CONCLUSION: Limitations include that we were only able to sample a small percent of the overall state population using VA data; accordingly, young people, women and children are underrepresented in this sample. Despite this, this study suggests that data obtained from electronic health records may be useful in predicting ILI on a regional basis. The combination of ICD-9 codes, vital signs, lab, and pharmacy data provided the best correlation with influenza. ICD-9 and lab counts

both contribute independently to prediction and should be considered to build a stronger model of prediction in our data.

(Tracking ID # 11057)

BACKGROUND: Antipsychotic medications are associated with potential adverse events among older patients, and recent studies report a high prevalence of use of these agents in U.S. nursing homes. Little is known, however, about antipsychotic use in Veterans Administration (VA) nursing homes, which, unlike their counterparts in the private sector, participate in a national formulary with a centralized pharmacy benefit manager. In this study, we estimated the prevalence of antipsychotic use by older VA nursing home patients and identified demographic, health status, and organizational factors associated with antipsychotic prescribing.

METHODS: We conducted a cross-sectional study of 3,692 Veterans over age 64, who were admitted between January 2004-June 2005 to 133 VA nursing homes, also known as Community Living Centers (CLCs). These patients had at least a 90-day stay and one drug dispensing record and were not admitted for respite or palliative care. We used VA Pharmacy Benefits Management dispensing data to examine antipsychotic prescribing. We used ICD-9 codes from VA inpatient and outpatient files in the year before admission and the Minimum Data Set to identify evidence-based indications for antipsychotic use (e.g., schizophrenia, dementia with psychosis). Independent variables included patient demographics, health status, and facility characteristics (urban/rural, region of US, bed size, presence of Alzheimers/Dementia Special Care Unit). We conducted multivariate analyses using Generalized Estimating Equations to identify the factors independently associated with receipt of an antipsychotic.

RESULTS: Overall, 25.7% (948/3692) of patients were prescribed an antipsychotic. Of these patients, 93% had regularly scheduled administration, and 90% received atypical agents. Only 59.3% of antipsychotic users had a documented evidence-based indication. Veterans with dementia but no psychosis were as likely as those with an evidence-

based indication to receive an antipsychotic (OR 1.10, 95% CI 0.82-1.47). Patients with aggressive behavior (OR 2.74, 95%CI 2.04-3.67), and those receiving anxiolytic/hypnotic medications (OR 2.30, 95%CI1.64-3.23) or drugs for dementia (OR 1.52, 95% CI 1.21-1.92) had higher odds of being prescribed an antipsychotic. Veterans residing in an Alzheimers/Dementia Special Care Unit were more likely to be prescribed an antipsychotic (OR 1.66, 95% CI 1.26-2.21). CONCLUSION: Antipsychotic prescribing is common in older VA nursing home patients, including those without a documented evidence-based indication for use. The odds of use are increased in Veterans residing in Alzheimers/Dementia Special Care Units and in those with aggressive behavior and taking concomitant anxiolytic/ hypnotics. Quality improvement efforts are needed in VA, as well as non-VA, nursing homes to reduce potentially inappropriate antipsychotic prescribing and increase the use of non-pharmacological behavior modification approaches. The effect on nursing homes of FDA antipsychotic warnings issued subsequent to the study period should be examined, both within and outside of the VA system.

RETAIL CLINICS EFFECTS ON PRIMARY CARE RELATIONSHIPS Rachel O Reid 1; J. Scott Ashwood 2; Mark W Friedberg 3; Ellerie Weber
4; Claude M Setodji 2; Ateev Mehrotra4. 1University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania ; 2RAND Corporation, Pittsburgh, Pennsylvania ; 3RAND Corporation, Boston, Massachusetts ; 4University of Pittsburgh, RAND Corporation, Pittsburgh, Pennsylvania. (Tracking ID # 11061)

BACKGROUND: Retail Clinics (RCs) are convenience-focused clinics located in retail stores. Staffed by nurse practitioners, they provide walk-in care for a limited set of acute and preventive concerns and saw 5 million visits in 2009. Physicians and policymakers are concerned that retail clinics may negatively impact primary care relationships. In theory, each RC visit to could represent one fewer visit to a primary care provider (PCP) and, therefore, one fewer opportunity to build a primary care relationship or receive preventive or chronic care. In this study we empirically evaluate these concerns.

METHODS: We performed a retrospective cohort analysis of a database of de-identified insurance claims from a sample of 14.8 million patients in 20 insurance markets from the years 20079. We sampled all patients who had an index visit to an RC for one of 11 simple acute conditions and randomly selected control patients who had an index visit to a PCP for one the same conditions.

We included 94,235 patients who were younger than 65 years, living within 20 miles of an RC, and continuously insured for 1 year before and after an index visit: 29,575 with RC index visits and 64,660 with PCP index visits. For each patient, we compared care delivered in the 365 days before and after the index visit. Using a difference-indifferences approach, we evaluated the impact of the RC visit on two proxies for a primary care relationship: (1) receipt of a preventive health examination or (2) having two or more visits to the same PCP. We used multivariate logistic regression to estimate the marginal effect of visiting a retail clinic on subsequent receipt of primary care.

RESULTS: Compared to visiting a PCP for a similar concern, visiting an RC was associated with 1.4% ($p=0.001$) increased likelihood of having a subsequent preventive health examination. Adjusted rates of preventive examinations were 27.2% before and 28.9% after an RC index visit, compared to 45.9% before and 46.2% after a PCP index visit. Compared to visiting a PCP, visiting an RC was associated with 2.5% ($p<0.001$) decreased likelihood of having two or more visits with the same PCP. The adjusted percentages of patients having two or more PCP visits were41.8% before and 42.8% after an RC index visit, compared to 51.8% before and 55.3% after a PCP index visit.

CONCLUSION: Compared to visiting a PCP for an urgent health condition, visiting an RC may modestly increase the likelihood of receiving subsequent preventive examinations and moderately decrease the subsequent likelihood of having multiple visits to the same PCP. It is possible that some preventive issues that can be addressed in an acute visit to a PCP cannot be addressed at a comparable visit to an RC. Concerning PCP continuity, after visiting RCs patients may substitute RC visits for PCP visits or may simply seek less

primary care. These first empirical analyses of the impact of RC care on PCP relationships find effects of mixed direction and modest magnitude. Physicians concerns that RCs will undermine primary care relationships may not be substantiated.

OUTPATIENT AND INPATIENT PAID MALPRACTICE CLAIMS AND THE FOCUS OF PATIENT SAFETY EFFORTS Tara F. Bishop 1; AndrewM. Ryan 1; Lawrence P. Casalino1. 1Weill Cornell Medical College, New York, New York. (Tracking ID # 11071)

BACKGROUND: Since the landmark Institute of Medicine Report, To Err is Human, there has been significant progress in patient safety, but most initiatives have centered around inpatient care. This study sought to compare the volume of paid malpractice claims for errors in the outpatient versus inpatient settings. The number and dollar amount of paid malpractice claims may be taken as an indicator of errors in each setting.

METHODS: Using data from the National Practitioner Databank (NPDB), we performed a cross-sectional comparison and trend analysis of malpractice payments for errors in the outpatient and inpatient settings. The NPDB is a repository of all malpractice claims paid on behalf of licensed health care providers. For the cross-sectional analysis, we limited our sample to claims paid in 2008. For the trend analysis, we examined payments made from 2004 to 2008. We only included payments made on behalf of a physician (MD or DO) including resident physicians. We excluded entries in which only disciplinary action by a credentialing or licensing body occurred. We calculated the absolute number and proportion of malpractice claims paid for physicians in the inpatient, outpatient, and both (for the same case) settings and used linear regression analysis to determine whether these proportions changed over time. We used the Chi-squared test to multiple logistic regression to compare differences in payments amounts by setting. We also performed chi-squared test to compare differences in the types of errors and outcomes of events by setting. RESULTS: In 2008, there were 10,535 malpractice claims paid on behalf of physicians. Of these payments, 5,020 or 47.7% were for errors in the inpatient setting, 4,487 or 42.5% were for errors in the outpatient setting, and 1,028 or 9.6% were for errors in both settings. The proportion of payments for errors in the outpatient setting increased a small but significant amount from 41.2% in 2004 to 42.6% in 2008 ($p=0.003$). Mean payment amount for errors in the outpatient setting was significantly lower than in the inpatient setting ($291,834 vs $369,227, $p<0.001$) as was median payment amount ($155,000 vs. $195,000, $p<0.001$). This difference remained significant even after accounting for differences in the type of error and patient and physician characteristics. In the outpatient setting, the most common types of errors were diagnostic (46.5%), treatment (22.5%), and medication (7.6%) errors. In the inpatient setting, the most common types of errors were surgical(35.4%), diagnostic (19.9%), and treatment (17.4%) errors. Obstetric(13.9% vs. 1.5%) and anesthesia (3.7% vs. 1.4%) errors were more common in the inpatient setting. In bivariate analysis, the proportion of the types of error was significantly different between the inpatient and outpatient settings ($p<0.001$). Major injury was the most common outcome in both the inpatient (37.2%) and outpatient (32.3%) settings.

A small but significantly higher percentage of inpatient malpractice payments were for an outcome of death (34.5% vs. 32.3%, $p<0.001$). CONCLUSION: A high proportion of paid malpractice claims are for errors in the outpatient setting. These findings suggest that we need similar focus on error reduction in the outpatient setting as has been done in the inpatient setting.

EFFECTS OF A WALKING INTERVENTION ON SYSTEMIC INFLAMMATION IN PERSONS WITH DIABETES MELLITUS AND PERIPHERAL ARTERIAL DISEASE Tracie Collins 1; Scott Lunos 1; James Hodges1. 1University of Minnesota, Minneapolis, Minnesota. (Tracking ID # 11073)

BACKGROUND: We sought to determine whether a walking intervention would reduce inflammation in patients with diabetes mellitus and peripheral arterial disease (PAD).

METHODS: We obtained blood samples from a consecutive subset of patients with diabetes mellitus and PAD (as defined by an ankle-brachial indexan objective measure of lower limb blood flow <0.9) who were part of a larger, two-arm, six-month trial. The two study arms were attention control and a home-based walking

intervention. All participants were contacted bi-weekly for six months and, during each call, the study coordinator discussed participants efforts to manage their diabetes mellitus and, as indicated, hypertension, hyperlipidemia, and smoking. For participants randomized to the intervention group, each phone call also included a stage of change based intervention to motivate the use of home-based walking at least three days each week for 50 minutes each session. Also, each intervention participant completed a 50-minute walking session with an exercise instructor one additional day each week. The study was funded by the American Diabetes Association. Participants completed baseline and six-month assessments of co-morbidities, exercise behaviors, and walking ability. Linear regression was used to assess the relationship between group assignment, walking ability, or exercise behaviors with each biomarker.
RESULTS: We obtained blood samples on 55 participants (control=25 and intervention=30). At baseline, median values for the biomarkers were as follows; soluble intercellular adhesion molecule (ICAM) 245.94, interleukin-6 (IL-6) 3.18, soluble vascular cell adhesion molecule (VCAM) 828.63, monocyte chemoattractant protein (MCP-1) 414.09, B2 microglobulin 2.80, total cholesterol 168.00, triglycerides 174.00, high-density lipoprotein (HDL) 40.00, low-density lipoprotein (LDL)81.00, and C-reactive protein (CRP) 2.82. There were no significant differences between the control and intervention groups in baseline characteristics with the exception in use of cilostazol (26% of the control group used this medication versus 8% of the intervention group, P=0.008). At 6 months and based on change in the intervention group minus change in the control group, we observed the following: ICAM 5.15 (SE 11.58, P>0.20), VCAM 29.62 (SE 48.99, P>0.20), total cholesterol 9.77 (SE 6.85, P=0.16), triglycerides 10.90 (SE 34.53, P>0.20), HDL 3.61 (SE 2.09, P=0.09), LDL 1.67 (SE 5.83, P>0.20), CRP0.19 (SE 1.41, P>0.20). In analyzing treadmill walking distance as a predictor of inflammation, we observed that ICAM changed by 1.81 (SE5.63, P>0.20); VCAM changed by 11.17 (SD 23.85, P>0.20), LDL by 0.95 (SE 2.77, P>0.20), and HDL by 0.57 (SE 1.04, P>0.20), for every 1 SD change in area under the curve for treadmill walking distance. We observed similar changes in biomarkers when looking at additional measures of walking ability including responses to the Walking Impairment Questionnaire and Exercise Behaviors Survey.
CONCLUSION: Our results suggest that some biomarkers of inflammation (ICAM, VCAM, total cholesterol, triglycerides, and LDL) may be improved by exercise in persons with diabetes mellitus and PAD.

Surprisingly, HDL which is traditionally managed with an increase in physical activity, did not improve as walking distance improved.
HEALTHCARE DISPARITIES EXPERIENCED BY ADULTS ON THE AUTISTIC SPECTRUM Christina Nicolaidis 1; Dora Raymaker 2; Katherine McDonald 3; Sebastian Dern 4; Elesia Ashkenazy 2; William Cody Boisclair 5; Amanda Baggs6. 1Oregon Health &Science University, Portland, Oregon ; 2Autistic Self-Advocacy Network, Portland, Oregon ;
3Portland State University, Portland, Oregon ; 4AASPIRE member at large, Berlin, N/A ; 5AASPIRE member at large, Atlanta, Georgia ;
6AASPIRE member at large, Burlington, Vermont. (Tracking ID # 11075)
BACKGROUND: There has been a great increase in the recognition of Autism Spectrum Disorders (ASD). Current estimates are that up to 1% of the adult population may be on the autistic spectrum. Though studies have shown that people with developmental disabilities experience significant disparities in care, most studies have recruited participants through disability services or institutional settings and may not have included the wide heterogeneity of ASD. Autistic adults who use the Internet represent an understudied population of healthcare users who may experience important barriers to care. Our objective was to identify disparities in healthcare for autistic adults who use the Internet, as compared to Internet users without disabilities.
METHODS: The Academic Autistic Spectrum Partnership in Research and Education (AASPIRE), a partnership

between researchers, autistic self-advocates, family members, healthcare workers, and disability service providers, used a Community Based Participatory Research (CBPR) approach where community members served as equal partners in each stage of the project. We conducted an online survey via the Gateway Project, an online registration system for research projects committed to inclusion, respect, accessibility and community relevance. Gateway Project participants, age 18 or older, completed an assessment of autistic traits (the Autism Quotient) and provided information on autism-related diagnoses. Gateway Project participants who reside in the US and self-identify as being on the autistic spectrum were invited to participate in a survey on unmet healthcare needs, healthcare utilization, healthcare satisfaction, barriers to healthcare, general and psychological well-being, and healthcare self-efficacy using standardized instruments. Our team of academic and community partners adapted all instruments to be accessible to autistic adults. We matched autistic participants by age and sex with non-autistic adults without disabilities and invited them to take the same survey. We analyzed data using Stata software. We used t-tests and chi-squared tests for bivariate analyses and used logistic and linear regression for multivariate analyses. Primary analyses include all adults who consider themselves to be autistic. Secondary analyses limit autistic participants to those who score 32 or greater on the Autism Quotient and to those who have formal medical diagnoses on the autistic spectrum.
RESULTS: 360 participants (199 autistic, 161 non-autistic without disabilities) completed the survey. Both groups had high educational attainment (>90% with at least some college), but the autistic group had lower income (53% vs. 29% with <$25,000 annually). In multivariate analyses, after adjustment for age, sex, race/ethnicity, personal and parental educational level, income, and type of health insurance, autistic adults had higher odds of having unmet health needs (physical health, OR 2.3, p=0.01; preventive health OR 2.0, p=0.045; mental health, OR 5.1, p<0.001), higher odds of using the emergency room within the past year (OR 3.2, p=0.001), lower odds of complying with preventive care such as pap smears (OR 0.32, p=0.006), lower satisfaction with health care (p<0.001), lower healthcare self-efficacy (p=<0.001), and a greater number of barriers to healthcare in each category (p<0.001). Secondary analyses limiting the autistic group to either those who had formal medical diagnoses or those who scored high on the AQ did not significantly alter the results.
CONCLUSION: Autistic adults who use the Internet report receiving significantly worse healthcare than Internet users without disabilities. Healthcare providers should be made aware of potential barriers to care for autistic adults - including adults such as those in our sample, with overall high educational attainment and the communication and intellectual skills necessary to use the Internet. Future research is needed to find ways to improve healthcare for adults across the entire autistic spectrum.
TWENTY PERCENT OF TENNESSEE MEDICAID RECIPIENTS WHO PARTICIPATED IN WEIGHT WATCHERS LOST 5% OR MORE OF THEIR INITIAL WEIGHT Nia S. Mitchell 1; Misoo Ellison 1; James Hill 1; Adam Gilden Tsai1. 1University of Colorado, Denver, Colorado. (Tracking ID # 11078)
BACKGROUND: Obesity and its associated medical problems are crucial issues for internists in the United States, as well as the health care system as a whole. Low socioeconomic groups have higher rates of obesity than the general population. Although there is some evidence that commercial weight loss programs are effective, they are still too expensive for the most vulnerable populations. In an effort to help control obesity, Tennessee Medicaid (TennCare) partnered with Weight Watchers to offer its recipients access to the weight loss program for a nominal fee. The aim of this study was to determine the weight change among adult Medicaid beneficiaries that participated in Weight Watchers.
METHODS: Weight Watchers is a well known commercial weight loss program that helps its participants lose weight through group support and information about healthy eating, portion control, exercise, and behavior modification. Participants attend weekly group meetings led by Weight Watchers employees who have successfully lost weight with the program. Program participants paid a $1 copayment for each visit and TennCare covered the other $10. The current study is a retrospective analysis of weight change among 1,192

overweight and obese TennCare recipients who participated in Weight Watchers in 2006 and 2007. Weight change in kg was calculated as the difference from the first date of participation to the last. Weight change was also calculated as percentage change from initial weight. Weight change was subsequently categorized as weight loss or gain of 0 to 5%, >5 to 10%, and >10%. Analyses were stratified by gender and by initial BMI category for women (overweight vs. obese) because the starting weights for males vs. females and for overweight vs. obese females were significantly different. The average weight loss was also calculated based on the number of meetings attended.
RESULTS: During the study period, 1,965 Medicaid recipients participated in the program and 1,192 individuals were eligible for analysis with at least one follow-up weight measurement. The average starting weight for females was 111.4 kg (SD=27.7) and the average starting weight for males was 144.3 kg (SD=43.0); and the average baseline BMIs for females and males were 41.1 (SD=9.4) and 45.4 (SD=13.1), respectively. The average weight loss for all participants was 3.0 kg, equal to 2.7% of initial weight. Twenty percent of participants lost 5% or more of their initial body weight while participating in the program. There was no statistical difference in weight loss between overweight or obese females or between males and females.
The average number of meetings attended was 9.9 (SD=10.2), with a range of 2 to 92 meetings and a median of 7. Over 13% of the participants (N=160) only attended 2 meetings. On average, these participants lost 0.5% (SD=6.4) of their initial weight. Over 23% of the participants (N=276) attended 13 or more meetings, and they lost an average of 6.4% of their initial weight.

CONCLUSION: Twenty percent of the TennCare recipients who participated in Weight Watchers lost a clinically significant amount of weight, even though the average weight loss among all participants was modest. Participants who attended more meetings were more likely to lose a clinically significant amount of weight. Obesity and its associated comorbidities place a significant burden on Medicaid budgets and on the primary care providers who treat Medicaid patients. Thus, partnerships that allow low-income patients to access weight loss programs may provide a valuable weight management tool and should be explored further.
NOMINAL GROUP TECHNIQUE TO IDENTIFY ATTRIBUTES OF TOP ATTENDING PHYSICIANS Nidhi Gupta Huff 1; Brita Roy 2; Carlos Estrada 3; Robert Centor 4; Analia Castiglioni 2; Lisa Willett 2; Stuart Cohen2.
1University of Alabama at Birmingham, Fultondale, Alabama ;
2University of Alabama at Birmingham, Birmingham, Alabama ;
3Birmingham VAMC, The University of Alabama at Birmingham, Birmingham, Alabama ; 4University of Alabama at Birmingham, Birmingham VAMC, Birmingham, Alabama. (Tracking ID # 11079)
BACKGROUND: Ward attending rounds remain a cornerstone of residency education; however, data is limited on characteristics that define exceptional attendings. We created a study to identify attributes of top ranked attending physicians.
METHODS: Internal medicine residents and students on general medicine services at an academic medical center participated in nominal group technique (NGT) sessions to generate a list of attributes describing their ward attending. Participants voted on attributes based on perceived importance. For attributes with three votes or more, six physicians independently assigned them to our five previously identified domains of teaching excellence: role modeling, teaching process, learning environment, team management, and setting expectations. Attendings were placed into top, middle, and bottom tertiles using a preexisting, standard evaluation (E-value). E-value rank was compared with the number of votes in each domain. Correlation between attending rank and number of votes within domains were calculated using Pearson Correlation Coefficient (r).
RESULTS: A total of 264 residents and students participated in 17 NGT sessions for 23 attending physicians. This generated 66 attributes, which fit within the five domains of teaching excellence. Top ranked attendings received the most votes in the teaching process domain (54% of votes); attributes included: sets aside time to

teach, explains the decision making process, teaching at the bedside, and asks questions. Attending rank and teaching process votes were significantly associated (r=.998; p=.036) with no significant trends in other domains. CONCLUSION: Teaching excellence in top rated attendings is characterized by engaging learners by explaining the decision making process and setting aside time to teach.

ACCURACY OF DO NOT RESUSCITATE (DNR) IN ADMINISTRATIVE DATA L. Elizabeth Goldman 1; Philip W. Chu 1; Dennis Osmond 1; Andrew Bindman1. 1University of California San Francisco, San Francisco, California. (Tracking ID # 11080)

BACKGROUND: Having a Do Not Resuscitate (DNR) order, defined as a physician order of DNR within 24 hours of admission, is strongly associated with in-hospital death. The Center for Medicare and Medicaid Services is beginning to require the collection of whether patients have DNR orders on admission that could be used as a risk adjustment variable in hospital quality assessments. The validity of this approach is partially dependent on whether DNR is accurately reported by hospitals. The objective of this study is to test the accuracy of a DNR data element in California administrative data, the only state that currently requires the collection of this information.

METHODS: We used an audit by registered nurses (RN) of 1673 medical records from 48 California hospitals to compare DNR coding in the 2005 Patient Discharge Data (PDD) to RN re-abstraction and determined whether patient characteristics were associated with coding accuracy. Subjects were selected using a probability sample of patients with acute myocardial infarction, community-acquired pneumonia, or congestive heart failure. Overcoding a DNR order was considered to have occurred when the PDD recorded a DNR order, and the RN reabstraction said there was none. Undercoding a DNR order was considered to have occurred when the PDD did not record a DNR order, and the RN abstraction did.

RESULTS: The PDD overcoded a DNR order in 191 (11.4%) records and undercoded a DNR order in 71 (4.2%) records. Among those overcoded, the record did confirm a DNR order in 99 (46.6%) but it was incorrectly documented in the PDD because the order was written more than 24 hours after admission. The odds of DNR being inaccurately coded increased significantly with patient years of age, [(overcoding OR1.03; p=0.002); (undercoding OR 1.04; p<0.0001)] and undercoding was higher among those patients who died (OR 2.01; p=0.007)]. CONCLUSION: Among hospitalized patients with one of three common medical conditions, DNR coding in administrative data is inaccurate in more than one in seven cases. While there are important reasons to include DNR status in risk adjusted mortality rates to judge hospital quality, the finding that the recording of DNR status is particularly problematic among patients who died suggests that this variable as currently reported by hospitals in California is invalid. Further work needs to be done in developing data reporting standards for DNR if it is to become a useful component in performance measurement.

BENEFITS OF WALKING THERAPY IN PATIENTS WITH DIABETES MELLITUS AND PERIPHERAL ARTERIAL DISEASE WHO ARE LIMITED BY LEG PAIN OR FATIGUE Tracie Collins 1; Winta Ghidei 2; Jasjit Ahluwalia3. 1University of Minnesota, Minneapolis, Minnesota ;
2University of Minnesota, Center for Health Equity, Minneapolis, Minnesota ; 3University of Minnesota, Executive Director, Center for Health Equity, Minneapolis, Minnesota. (Tracking ID # 11083)

BACKGROUND: Patients with diabetes mellitus and peripheral arterial disease (PAD - defined by an ankle-brachial index - an objective measure of lower limb blood flow - <0.9) are limited by walking from both leg pain and fatigue or fatigue only. Commonly health care providers focus on leg pain, but not fatigue when managing patients with PAD. Walking therapy is an important treatment option for patients with PAD to reduce leg pain and improve quality of life. We conducted a secondary analysis of a clinical trial in which we randomized patients with diabetes mellitus and PAD to an attention control and a home-based walking intervention. This secondary analysis compared treadmill walking

distance, both maximal and onset to pain, at baseline and at 6 months in both the intervention and control groups for those stopping the treadmill secondary to leg pain and fatigue, or fatigue only. METHODS: All participants (n=145) were contacted bi-weekly for six months and, during each call, the study coordinator discussed participants efforts to manage their diabetes mellitus and, as indicated, hypertension, hyperlipidemia, and smoking. Participants completed baseline and six-month assessments of treadmill walking distance, both maximal walking distance and onset to pain distance. Linear regression was used to assess the relationship between group assignment and each outcome.
RESULTS: Of the 145 patients randomized (mean age 66.5 years, SD10.1 years), eight terminated treadmill testing for reasons other than leg pain and fatigue or fatigue only, 106 terminated treadmill testing secondary to leg pain and fatigue (control=54; intervention=52), and 31 terminated testing secondary to fatigue only (control=12; intervention=19). Comparing change from baseline to 6-months among participants who terminated treadmill testing because of leg pain and fatigue, control participants improved their maximal walking distance by 48.0 (20.9) meters as compared to 24.3 (21.6) meters for intervention participants (p=NS) and onset to pain distance increased by 50.2 (21.7) meters for control participants as compared to 54.6 (28.4) meters for intervention participants (p=NS). For persons who terminated treadmill testing for fatigue only, change from baseline to 6-months in maximal walking distance was 28.4 (52.7)) meters for control participants compared to46.7 (31.7) meters for intervention participants (p=NS) and onset to pain distance was 38.0 (52.6) meters for control participants as compared to 139.1 (34.6) meters for intervention participants (p=0.10). CONCLUSION: A home-based walking intervention may have more benefit for improving onset to pain distance as compared to maximal walking distance in persons with diabetes mellitus and PAD who are limited by fatigue (i.e., deconditioning). Further research is needed to address the benefits of home-based walking for persons with diabetes mellitus and PAD who are limited not only by leg pain but also fatigue.
EQUITY IN THE RECEIPT OF TAMIFLU DURING THE PANDEMIC FLU? William Shrank 1; Sebastian Schneeweiss 2; Michael A. Fischer 2; Jerry Avorn 2; Greg Brill 3; Julie Slezak 4; Josh Liberman 5; Troy Brennan 6; Niteesh Choudhry2. 1Brigham and Womens Hospital, Harvard Medical School, Boston, Massachusetts ; 2Brigham and Womens Hospital, Boston, Massachusetts ; 3Harvard University, Boston, Massachusetts ; 4CVS Caremark, Chicago, Illinois ; 5CVS Caremark, Hunt Valley, Maryland ; 6CVS Caremark, Woonsocket, Rhode Island . (Tracking ID # 11084)
BACKGROUND: Tamiflu is a potentially life-saving therapy for the management of influenza. During the recent pandemic flu, lay press reports raised concerns about differential access to Tamiflu based on patient income. However, little is known about the relationship between patient characteristics and receipt of Tamiflu therapy. In a sample of patients insured by a large, national pharmacy benefits manager, we evaluated patient characteristics associated with Tamiflu receipt during the pandemic flu.
METHODS: We identified patients continuously enrolled in a pharmacy benefit insurance plan from CVS Caremark between October, 2008 and May, 2010. Pharmacy claims were used to examine whether patients received a prescription for prophylactic or therapeutic doses of Tamiflu during the study period. Independent, patient-level variables included gender, age, geographic region, number of unique medications (a proxy for comorbidity) and median income in zip code of residence. We fit a logistic regression model to assess patient characteristics associated with Tamiflu receipt. In addition, we used county-level information about rates of influenza diagnosis during the study period for 19 states to assess the relationship between patient characteristics and Tamiflu receipt, controlling for disease burden.
RESULTS: The study cohort consisted of almost 26 million patients throughout the US who, on average, were 41 years old; 52.5% were female, and they used an average of 1.9 unique medications in the first 4 months of the study period. Overall, 1.26 million patients (4.8%) filled a prescription for Tamiflu during the study period. In multivariate analyses, beneficiaries aged 5064 and 65 or older had 51.2% and77.1% lower odds, respectively,

of receiving Tamiflu than young adults (age 1834). (p<0.001 for both) Patients in the Southern U.S. and those taking more medications were more likely to receive Tamiflu. (p<0.001 for both) Patients in the highest income quintile had 32% greater odds of receiving Tamiflu than those in the lowest quintile. In the 19 states with influenza diagnosis data, we found no statistically significant relationship between rates of diagnosis and the likelihood of Tamiflu receipt. Geographic variations became insignificant after controlling for influenza disease burden, and the relationship between income and Tamiflu receipt strengthened. Patients in the highest income quintile had 64% greater odds, and patients in the second highest quintile had 32% greater odds, of receipt of Tamiflu than those in the lowest quintile. (p<0.001 for both)
CONCLUSION: We found that income in the zip code of residence is more strongly related to Tamiflu receipt than rate of influenza diagnoses during the pandemic flu. These findings corroborate concerns about equity of treatment in the setting of pandemic flu, and they call for more equitable solutions to distributing potentially life-saving treatments.
A POOLED SAFETY ANALYSIS OF ROFLUMILAST FOR THE TREATMENT OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE: TIME TO ONSET, DURATION AND SEVERITY OF ADVERSE EVENTS B Wagner 1;

PMA Calverley 2; LM Fabbri 3; KF Rabe 4; H Mosberg5. 1Forest Research Institute, Jersey City, New Jersey ; 2University Hospital Aintree, Liverpool, N/A ; 3University of Modena &Reggio Emilia, Modena, N/A ; 4Krankenhaus Grohansdorf, Grohansdorf, Germany; 5Nycomed, Konstanz, N/A . (Tracking ID # 11086)
BACKGROUND: The Centers for Disease Control (CDC.gov) recently reported that chronic obstructive pulmonary disease (COPD) rose from previously being the 4th leading cause of death in 2008 to 3rd in the US and its incidence is believed to be increasing in the US. Despite current treatments, patients with COPD continue to experience exacerbations, which can accelerate the progression of the disease and increase mortality. Therefore, there is an important unmet need to achieve optimal treatment for patients to help reduce exacerbations of COPD. The selective phosphodiesterase 4 (PDE4) inhibitor roflumilast (ROF) was shown to significantly reduce the incidence of moderate or severe COPD exacerbations by 17% compared with placebo and to improve lung function in 2 identical 12-month pivotal trials in patients with severe airflow limitation, bronchitic symptoms, and a history of exacerbations. In two 6-month studies of moderate-to-severe COPD patients treated concomitantly with salmeterol or tiotropium, roflumi-last also significantly improved lung function and reduced the proportion of patients experiencing a moderate or severe exacerbation. To further characterize this new treatment, the safety and tolerability of roflumilast were analyzed in a pooled COPD safety population.
METHODS: The COPD safety pool comprised 12,054 patients with moderate-to-very severe COPD from 14 randomized, double-blind studies of ROF 250 g (n=797) or 500 g (n=5766) once-daily vs placebo (n=5491). The incidence of the most frequent (2% higher for ROF vs placebo [PBO]) individual adverse events (AEs), serious AEs, and rates of withdrawals due to AEs are reported for all dose groups. The

incidence by severity (by system organ class [SOC]), duration, and time to onset for the most frequently experienced AEs are reported for the 500 g dose.
RESULTS: AE incidence was 67.2%, 60.7%, and 62.8% and serious AEs was 13.5%, 7.2%, and 14.2% for ROF 500 g, 250 g, and PBO, respectively. Withdrawals due to AEs were 14.3% for ROF 500 g, 8.9% for ROF 250 g, and 9.2% for PBO. The most frequently reported AEs were exacerbations (19.8%, 21.2%, 23.1%), diarrhea (10.1%, 4.9%,2.6%), decreased weight (6.8%, 0.8%, 1.8%), nausea (5.2%, 2.3%, 1.4%), and headache (4.6%, 3.5%, 2.0%) for ROF 500 g, 250 g and PBO, respectively.For ROF 500 g compared to PBO, between-treatment weight loss was 2.14 kg (P<0.0001); ~80% of patients regained half of their lost weight by 3 months after ROF discontinuation. The incidence of infections was similar (25.9% ROF 500 g vs 27.5% PBO), with no difference in pneumonia (1.8% vs 2.0%, respectively). Fewer cardiovascular AEs were reported with ROF 500 g (5.7%) than PBO (5.9%); no difference in potential proconvulsant effects was seen. Mesenteric

vasculitis was not seen in any patient, and depression or suicidality affected very few patients in either group (3 for ROF and 1 for PBO during treatment and 2 for ROF 3 weeks after treatment cessation). AE frequency by SOC at any intensity was similar (2% difference) for ROF 500 g and PBO, except for moderate respiratory, thoracic, and mediastinal disorders, which were 2% lower with ROF and mild/ moderate gastrointestinal disorders, or mild/moderate nervous system disorders were 2% higher with ROF. For time to onset for AEs, during the first 4 weeks AE incidence was higher with ROF 500 g (27.6%) than PBO (14.1%), while the incidence of AEs with onset later than 4 weeks was higher with PBO (85.9%) than ROF 500 g (72.4%). The majority of AEs in all treatment groups lasted <4 weeks. Weight decrease, diarrhea, nausea, and headache were more often experienced for <4 weeks with ROF 500 g vs PBO. For AEs of 26 weeks duration, there were slightly more AEs in patients in the ROF 500 g group vs PBO. In most cases, COPD exacerbations and diarrhea lasted <4 weeks.
CONCLUSION: In this large safety population of moderate-to-very severe COPD patients, oral, once-daily roflumilast was well tolerated. No unexpected AEs related to roflumilast treatment were identified. The most common AEs were generally mild-to-moderate in severity and short-lived (<4 weeks).

PERCEPTIONS OF ALERT FATIGUE BY PCPs USING AN INTEGRATED ELECTRONIC HEALTH RECORD

Hardeep Singh 1; Christiane Spitzmueller 2; Mona Sawhney 1; Donna Espadas 1; Varsha Modi 1; Dean Forrest Sittig3. 1VA Health Services Research and Development Service (VA HSR&D) Center of Excellence, Michael E. DeBakey Veterans Affairs Medical Center, Houston, Texas ; 2Department of Psychology, University of Houston, Houston, Texas ; 3University of Texas Health Science Center, Houston, Texas . (Tracking ID # 11088)

BACKGROUND: Integrated electronic health records (EHRs) facilitate communication and overcome previous concerns about missing clinical information during primary care visits. The Veterans Affairs (VA) EHR uses the View Alert notification system to generate asynchronous alerts to clinicians about significant events of various priorities (e.g., diagnostic test results, referrals, orders for signature, communication from other providers). We evaluated the extent to which EHR-based notifications were acted upon and their potential to cause primary care providers (PCPs) to perceive too much information (information overload) or feel overwhelmed by the quantity of information they receive (alert fatigue).
METHODS: We conducted a cross-sectional, web-based survey of VA PCPs to assess their perceptions and practices related to alert management. We developed initial survey items after an extensive literature review and refined the survey content after pilot testing with several PCPs and soliciting expert input. The final survey tested the following constructs: 1) follow-up action on high-priority alerts; 2) follow-up action on all alerts; 3) information overload; 4) alert fatigue. We also assessed individual PCP characteristics and their alert burden. We used a large administrative VA database to identify all PCPs with a minimum patient panel size of 250, a strategy designed to exclude trainees and subspecialists. The survey was administered through a commercial internet-based survey service. Invitation emails and subsequent reminders were followed by telephone attempts to reach non-respondents.
RESULTS: Of 5001 PCPs invited, 2590 (51.8%) responded. Characteristics of respondents included 55.4% female; 31.1% non-white, and31.5% non-physician providers; 82.1% had 2 or more years in VA practice, and 49.0% had prior experience using a non-VA EHR. Respondents reported a median alert burden of 63 per day (range 1-500); 54.1% perceived over half of their alerts to be unnecessary. Regarding actions on alerts, 93.2% reported they followed up on all high-priority alerts, whereas only 77.6% reported they followed up on all alerts. Just over two-thirds of PCPs reported perceived information overload (68.7%) and alert fatigue (67.3%). The majority (81.1%) believed managing alerts took too much time away from normal duties, and 87.3% reported that they used personal time (after hours or weekends) to manage alerts through remote EHR access or working in the office. About a third (30.5%) reported receiving some protected clinical time to manage alerts; compared to those without protected time, fewer respondents in this group indicated they experienced

information overload (64.9% vs. 70.7%, P=.004) and alert fatigue (64.4 vs. 68.5%, P<.05).
CONCLUSION: In a national survey of VA PCPs, the majority of respondents endorsed information overload and fatigue related to large numbers of EHR-based asynchronous alerts. Not all EHR alerts were considered necessary, and responses suggest that a significant proportion of alerts are not acted upon. PCPs with protected (i.e., paid) time to manage alerts were marginally less likely to report alert fatigue. Future research is needed to quantify the various types of alerts PCPs receive and to review the necessity of all types of alerts to reduce alert volume.
EFFECTS OF AN EDUCATIONAL INTERVENTION ABOUT TOBACCO USE ON MEDICAL STUDENTS IN ARGENTINA Jonatan Konfino 1;
Jonatan Konfino 2; Raul Mejia 2; Daniel Ferrante 3; R. Iermoli 2; Eliseo Perez-Stable4. 1Hospital de Clnicas Jos de San Martn, Universidad de Buenos Aires, Argentina, N/A; 2Hospital de Clnicas Jos de San Martn, Buenos Aires, N/A; 3Ministerio de Salud de la Nacin, Buenos Aires, N/A;
4University of California San Francisco, San Francisco, California. (Tracking ID # 11090)
BACKGROUND: In Argentina smoking prevalence among medical students is 30% and similar to that in the general population. The objective of this study was to implement and evaluate a brief educational intervention about tobacco use on fourth year medical students in Buenos Aires.
METHODS: At the beginning of the fourth year of the 6-year medical school, students assigned to rotations at the Universidad de Buenos Aires Hospital de Clinicas were divided into four groups. Each group attended classes at specific locations with different teachers and there was no structured contact among the different groups. Students were assigned to intervention or control based on a cluster-randomized trial design. All fourth year medical students from the Hospital de Clnicas were invited to participate in March 2009. Participants completed the Global Health Professions Student Survey (GHPSS). About half of the students then attended the modified Spanish version of the Rx for

Change Course, about tobacco cessation for students in the health sciences. Three months later, all participants completed the GHPSS againRESULTS: We invited 354 students to participate and 299 (84%) accepted. Of these 299, 70% were women, 26% had an outside job and 20% lived alone. The median age was 23 years. Although 88 (29%) were smokers, only 50 (57%) smoked cigarettes daily. Among smokers, 78% were women. Among the 299 students, 51% were exposed to second hand smoke (SHS) in their home in the previous week and 90% were exposed outside their homes. There was a high level of knowledge regarding tobacco consumption as 93%of the students answered correctly all the questions such as Smoking during pregnancy increases the risk of disease in the newborn, such as Sudden Death Syndrome? Only 3%of students had ever received information about smoking cessation and most were interested in receiving it for themselves or for their future patients. 40% of respondents considered that medical advice or smoking cessation counseling by physicians was not effective. No significant changes were observed in tobacco consumption or in the students beliefs about cessation counseling after the implementation of the educational intervention.
CONCLUSION: Providing knowledge on tobacco did not change students consumption or attitudes about tobacco use and cessation. Teaching medical students about helping their patients quit smoking should be a priority in Latin American medical education. New educational strategies will need to be developed to modify students attitudes and behavior about tobacco use.
THE EFFECT OF ELECTRONIC MEDICAL RECORD ALERTS ON PROCESSES OF CARE RELATED TO PREVENTING FALLS IN COMMUNITY-DWELLING ELDERLY PATIENTS David R. Goldmann 1;
Craig A Umscheid 1; Peter Gabriel 1; Mark Weiner 1; Susan Day 1; Asaf Hanish 1; Jesse Chittams 1; Bruce Kinosian2. 1University of Pennsylvania, Philadelphia, Pennsylvania; 2University of Pennsylvania/Department of

Veterans Affairs, Philadelphia, Pennsylvania. (Tracking ID # 11092)
BACKGROUND: Falls represent a significant cause of morbidity and mortality for vulnerable elders. Electronic medical records (EMR) have the potential to educate providers about fall prevention and simplify providing indicated care. We tested whether active or passive EMR alerts with links to order sets for management resources improved guideline-adherent fall prevention by generalists compared to usual care for community-dwelling elderly patients.
METHODS: We used a concurrent cohort design to measure two fall-related care processes (physical therapy referral and adjustment of high-risk medications) during three study periods: (1) no intervention (8 months), (2) a passive alert recommending physical therapy (PT) referral (6 months), and (3) an active alert recommending medical review for culprit drugs (6 months). Eligible patients 1) were 70 or older; 2) had been seen at least twice yearly during any of the two years prior to the beginning of the study by general internal medicine physicians in the three study practices (clinics A, B and C); and 3) responded during the study period to an eight-item health assessment questionnaire (HAQ), which included two items on past falls and fear of falling. The passive alert (Fig 1) containing fall-related assessment actions, resource links, and a PT referral link was seen by clinicians in all 3 practices in Period 2; the active alert (Fig 1) indicating that a high-fall risk medication was on the patients medication list and providing links to medication substitution protocols and other resources was seen in clinics B and C in Period 3. An educational intervention was delivered to all practices between the two alert periods. The passive alert was placed in the best practices section of the EMR; the active alert appeared on the screen and required a response before the provider could proceed. We
compared PT referrals, change in high-risk medications, and responses to the alerts across the practices within periods and across periods. RESULTS: In Period 1, 1377 of 3718 (37%) eligible patients answered the HAQ, with 392 of the 1377 (28.5%) answering positively to one or both falls questions. The percentage of those answering positively was not significantly different among the practices. In Period 2, 14/192 passive alert firings elicited a direct response from the clinician (7.3%); in Period 3, 41/ 184 passive alert firings elicited a direct response (22%). Of 21 concurrent active firings of the active alert in Period 3, all elicited a response. The medication list was reviewed in 12 (57%), and in 4 cases culprit drugs were stopped (19%). The Table illustrates how the proportion of PT referrals changed across the three study periods and practices.
CONCLUSION: One-time alerts to initiate preventive measures in elderly patients at increased risk for falls prompted a modest increase in PT referrals in 1 of 3 general internal medicine practices during a period in which an active alert regarding fall-risk related medication was operating concurrently. While very high-risk medications were present in only a minority of those elders at risk for falling, use of an active medication alert was associated with increased response to the passive PT referral alert.

COMMUNITY HEALTH CENTERS OUTPERFORM PRIVATE PHYSICIAN OFFICES ON AMBULATORY CARE PERFORMANCE MEASURES L. Elizabeth Goldman 1; Philip W. Chu 1; Max J. Romano 2; Randall S.

Stafford3. 1University of California San Francisco, San Francisco, California ; 2Johns Hopkins University, Baltimore, Maryland ;
3Stanford University, Palo Alto, California . (Tracking ID # 11093)
BACKGROUND: Community health centers (CHC) serve as a safety-net for many low-income and minority patients. Many are designated as Federally Qualified Health Centers, Federally Qualified Health Center look-alikes, and Indian Health Centers that receive cost-based reimbursement to provide comprehensive services to patients with higher burdens of chronic disease. Under health care reform, continued safety-net support will be predicated on demonstrated quality and efficiency. Currently, there is little data directly comparing the quality of safety-net care to that in private offices and none account for patient social and medical complexity.

METHODS: We examined the performance of CHC to private practice physicians on 18 previously established outpatient quality indicators using the 20062008 National Ambulatory Medical Care Survey, a national sample of office-based and community health center-based physician visits. CHC surveyed included Federally Qualified Health Centers, Federally Qualified Health Center look-alikes, and Indian Health Centers. Quality indicator performance was defined as the percentage of applicable visits receiving appropriate care. We compared unadjusted performance, as well as adjusted for patient age, sex, type of insurance, number of chronic diseases, depression, median zip code percent poverty and bachelors degree to account for visit complexity.
RESULTS: Across all U.S. providers, performance on the 18 indicators was variable. Adherence ranged from 14% to 100%. Compared to private office care, however, CHCs performed better on 6 indicators ($p<0.05$) and no differently on 11 indicators. Adjusting for visit complexity, CHCs performed better on 8 indicators and no differently on the remaining indicators.
CONCLUSION: CHC provide as good or higher quality care on select well established ambulatory care measures for patients in the setting of a greater chronic disease burden and socioeconomically complex patients. Future work should monitor performance on ambulatory care quality indicators with implementation of reimbursement modifications and performance incentives.
Table Private Practice Compared to CHC Performance on Quality Indicators
ENHANCING RESIDENTS CLINICAL SKILLS IN SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT FOR SUBSTANCE USE DISORDERS Neda Ratanawongsa 1; Jennifer Manuel 1; Daniel Ciccarone 1; Jennifer Hettema 2; Brad Shapiro 1; Sharad Jain 1; Diana Coffa 1; Carrie Cangelosi 3; Jacqueline Tulsky 1; David Hersh 4; Paula Lum1. 1UCSF, San Francisco, California ; 2University of Virginia, Charlottesville, Virginia ; 3San Francisco General Hospital, San Francisco, California ; 4San Francisco Department of Public Health, San Francisco, California . (Tracking ID # 11096)
BACKGROUND: Although substance use disorders cause significant morbidity and mortality in their patient populations, many internal medicine residents are not competent or confident in their skills with screening, brief intervention, or referral to treatment (SBIRT). In needs assessment surveys at our county hospital, residents who ranked discomfort and lack of experience as significant barriers were less confident in their abilities to engage in SBIRT, and half of our continuity clinic patients reported lack of counseling about substance use by their providers. To respond to this need for experiential clinical learning, we implemented and evaluated two specific methodologies within an SBIRT residency curriculum: a narrative reflection clinical case discussion and a clinical observation checklist exercise.
METHODS: Beginning in July 2009, we implemented an 8-week, 32-hour longitudinal SBIRT curriculum for internal medicine residents, comprised of small group discussions, motivational interviewing (MI) role-play, and site visits to local substance use treatment programs. To respond to gaps in experiential learning, we developed a narrative reflection-based case discussion facilitated by SBIRT-trained clinical faculty, in which residents were asked to write about and discuss a memorable experience talking with a primary care patient about drug or alcohol use that was particularly rewarding or challenging. Reflection prompts asked about challenges and

rewards in the encounter, helpful people/resources, wishes for what could have been different, questions/insights in caring for patients with substance use disorders, and goals for the next conversation. In July 2010, adapting SBIRT skills card and the validated Behavioral Change Counseling Index, we developed a clinical observation checklist to track residents implementation of SBIRT skills with their continuity patients comprised of check-off boxes for specific SBIRT tasks, rating scales for communication style, and qualitative comments for what residents should keep, stop, and start doing. We implemented the checklist in a formative feedback exercise in which trained faculty observers rated residents interactions with 2 clinic patients, followed by a debrief and goal-setting for future

practice-based improvement. Using an editing analysis style, we coded the qualitative comments from the narratives, discussions, rating checklists, and debriefings about insights, challenges, and rewards in residents SBIRT interactions.

RESULTS: To date, 32 residents have participated in at least 2 clinical case reflection exercise discussions and at least 1 observation checklist exercise. Qualitative analysis from the narrative reflections/discussions reveals that residents felt increasing self-efficacy applying MI skills to engage in discussions about substance use with patients whom they found frustrating: It was really nice to just set aside his other, numerous, health concerns and focus on this issue of central concern to him. For me, relaxing about the time pressures allowed much more of my recent and past training in strong interpersonal communication and motivational interviewing to come out, in a reasonably natural way or It was rewarding to listen to his perspective on his ETOH, why he drinks and his own very good insights into the negative sides of drinking. However, residents cited lack of time, competing responsibilities, lack of precepting support, and patient resistance as continued barriers to applying SBIRT skills in clinic: I wish I had a bit more time to chat about her life, her family, and her daily struggles or I wish we could have had more time to talk about his alcoholism. Pt has other medical issues including diabetes, which he is very concerned about and he wanted to address that. Analysis of qualitative checklist data revealed that residents screened skillfully for drug use disorders and employed patient-centered listening skills, while struggling with rolling with resistance and formulating specific action plans. Residents set objectives for themselves to assess for drug use disorders more systematically and employ MI skills more regularly across other behavior change topics.

CONCLUSION: In this SBIRT residency curriculum, reflective practice exercises using narrative-prompted facilitated discussions and clinical observation exercises revealed improving self-efficacy and improving MI skills in conversations with patients about substance use disorders, but also continuing challenges related to systems-based practice and rolling with patient resistance. These clinical exercises suggest that experiential learning, using structured reflection and observation tools, is a valuable educational method for identifying continuing needs and evaluating the impact of a competency-based SBIRT curriculum.

A CLINICAL RISK INDEX FOR LONG TERM SURVIVAL OF HOSPITALIZED OLDER PATIENTS Kala M. Mehta 1; Edgar Pierluissi 1; W. John Boscardin 1; Katharine A. Kirby 1; Louise C. Walter 1; Mary-Margaret Chren 2; Robert M. Palmer 3; Steven Counsell 4; C. Seth Landefeld1. 1Division of Geriatrics, University of California, San Francisco, San Francisco, California ; 2Department of Dermatology, University of California, San Francisco, San Francisco, California ;
3Division of Geriatric Medicine and Gerontology, University of Pittsburgh, Pittsburgh, Pennsylvania ; 4Indiana University Center for Aging Research and Department of Medicine, Indiana University School of Medicine, Indianapolis, Indiana . (Tracking ID # 11099)

BACKGROUND: Predicting long term survival in hospitalized older adults may help guide decision-making for patients, families and clinicians. There are no long-term prognostic indices for this population. Thus, our

objective was to develop and validate a clinical index for older, hospitalized adults in a cohort with near-complete mortality data up to 15 years.
METHODS: We developed this prognostic index in 1482 patients >=70 years discharged from the general medical service of a teaching hospital (mean age, 79.6 years; 61% female) and validated it in 1564 similar patients discharged from another teaching hospital (mean age80.5 years, 67% female). All patients were followed until death or 10 years after discharge. Independent predictors of mortality were examined using Kaplan-Meier survival analysis. The clinical index was identified using multiple Cox proportional hazards analyses with a best subsets method of variable selection.
RESULTS: The cumulative incidence of death at 1, 5, and 10 years was 30%, 66%, and 86%, respectively. In the development group, independent (p, 0.01) risk factors for death were older age; male gender; >=2 dependent activities of daily living (ADL) at hospital discharge; body mass index<=18; chronic kidney disease; congestive heart failure; chronic lung disease; cancer; and severe cognitive impairment. A clinical risk index with these risk factors stratified patients according to risk of death (Table 1). CONCLUSION: Using clinical information at hospital discharge, this risk index accurately stratified hospitalized older adults according to their risk for death over 10 years. Risk for death over time differed greatly according to the clinical index: few patients with low predicted risk died in one year, and almost all patients with high predicted risk had died by 10 years.
Table 1. Death rates according to quintities of predicted risk derived from the development cohort at 1, 5, and 10 years.
MEDICARE POST-HOSPITALIZATION SKILLED NURSING BENEFIT IN THE LAST SIX MONTHS OF LIFE
Katherine N Aragon 1; Kenneth Covinsky 1; Yinghui Miao 1; W John Boscardin 1; Alexander Smith1.
1University of California San Francisco, San Francisco, California. (Tracking ID # 11101)
BACKGROUND: Older adults often transition to skilled nursing facilities (SNFs) following acute hospitalization in the last months of life under the Medicare SNF benefit. However, current Medicare policy prohibits concomitant payment for both SNF and Hospice services. We sought to examine patterns of SNF use following hospitalization in the last 6 months of life.
METHODS: We used the Health and Retirement Study (HRS), a nationally represented study of older adults, linked to Medicare claims data. From Medicare claims, we determined the number of individuals age 65+ who used the SNF benefit in the last 6 months of life following hospitalization, and their admitting diagnosis to SNF. Using linked data from the HRS, we examined demographic, social, and clinical correlates of SNF use.
RESULTS: Our sample included 4,516 patients who died between 1994 and 2006 (mean age 83 [SD 8], 54% female, 87% white). Age-adjusted use of the SNF benefit in the last 6 months of life increased from 17% in 1994 to 36% in 2006. The most common admitting diagnoses were heart failure (9%), hip fracture (6%), and rehabilitation (5%). Use of the SNF

benefit was greater among patients who were: older (>85 36%, <85 26%), poorer (lowest quartile of net worth 34%, highest quartile 28%), and did not have cancer (no cancer 32%, cancer 26%) (all p<.001). These differences persisted after adjustment for age, sex, race/ethnicity, marital status, educational attainment, region, chronic conditions, and year of death. After using the SNF benefit 18% of patients enrolled in hospice and 27% died in a hospital. Among patients who died in 2006, 14% used the post-hospitalization SNF benefit 2 or more times in the last 6 months of life.
CONCLUSION: Over one-third of older adults now receive care in a SNF at the end of life under the Medicare SNF benefit. Many older adults shuffle between the hospital and SNF at the end of life. Although Medicare policy prohibits payment for hospice when patients are using the SNF benefit, many patients use the benefit near the end of life, suggesting a need to incorporate palliative services into the Medicare SNF benefit.
FACTORS ASSOCIATED WITH OBESITY IN A PRIMARY CARE POPULATION Adam Gilden Tsai 1; Jeanne Rozwadowski 2; Rachael Meir 3; David Brody 3; Jeanette Waxmonsky1. 1University of Colorado, Denver,

Colorado; 2Denver Health and Hospitals, Denver, Colorado;
3Denver Health Managed Care, Denver, Colorado. (Tracking ID # 11102)
BACKGROUND: Obesity is more prevalent among African-Americans and Hispanics as well as persons of lower socioeconomic status (SES). Lack of health care access and lower SES may also be associated with minority status and obesity. This study attempts to determine whether, in an outpatient health care setting, the relationship between race/ ethnicity and obesity could be explained by health care utilization or by poverty.
METHODS: This was a cross-sectional analysis of adult patients aged 1865 seen in primary care clinics within the past year with documented weight and height. Underweight individuals and women who had been pregnant in the last year were excluded. Weight categories were defined by body mass index (BMI): normal weight (1924.9 kg/m2), overweight (2529.9 kg/m2), obesity (3039.9 kg/ m2), and morbid obesity (>40 kg/m2). The roles of demographic and clinical factors as predictors for being in a higher BMI category were analyzed using ordinal logistic regression. Socio-demographic factors (race/ethnicity, language, household income) were assessed from data collected routinely within clinical encounters. Burden of co-morbid disease was assessed using the Chronic Disease and Disability Payment System, a validated measure for use in Medicaid populations.
RESULTS: Of the 23,428 patients, 25% were non-Hispanic Whites, 51% were Hispanic, and 19% were African-American. Obesity prevalence was 43% overall (compared to 34% nationally). Whites had a lower prevalence of obesity (39%) than Blacks (44%) or Hispanics (47%); $p<0.001$ for both comparisons. In multivariate analyses, all factors were significant except language, % of federal poverty level, and number of visits (see tables). The factors most strongly associated with greater odds of obesity were: female gender, Latino ethnicity, African-American race, increasing age, increasing co-morbidity index, and use of >4 medications.
CONCLUSION: Female gender, Latino ethnicity, African-American race, increasing age, increasing co-morbidity, and medication count are independently associated with obesity. Household income (% of federal poverty level) was not associated with obesity in this analysis. This may be because our patient population is nearly all low income (97% of persons at or below 200% of federal poverty level in the current analysis). Alternatively, this may be explained by similar utilization of care within this system. These results suggest that, in a public health care system with a uniformly low SES group of patients, the association between race/ethnicity and obesity is not explained by poverty or by differential health care utilization.
SHARED DECISION MAKING IN PSA TESTING Alison Rose Landrey 1;
Daniel D Matlock 2; Laura Andrews 1; Thomas D Denberg3. 1University of Colorado Hospital, Denver, Colorado ; 2University of Colorado Hospital, Aurora, Colorado ; 3Atrius Health and Harvard Vanguard Medical Associate, Boston, Massachusetts . (Tracking ID # 11103)
BACKGROUND: With substantial evidence indicating the equivocal benefit of the prostate specific antigen (PSA) test in screening for prostate cancer, the United States Preventive Task Force suggests that a clinician should not order the PSA test without first discussing with the patient the potential but uncertain benefits and the known harms of prostate cancer screening and treatment. Other professional societies have similar recommendations. Evidence also suggests that many men are tested without this discussion. There is thus a need to develop effective ways to aid patients and physicians in having such discussions. This project examines if a low literacy, one-page flyer outlining the risks and benefits of the PSA test, and encouraging patients to talk to their provider about this test, increases the rate of discussions surrounding PSA testing.
METHODS: The flyer was developed iteratively among practitioners at the University of Colorado and was designed for people with a 4th grade reading level. Men between the ages of 50 and 75 who were scheduled for an upcoming annual visit were randomized to either receive the flyer in the mail or no intervention (n=303).Our primary outcome was documentation of discussion of PSA testing. Secondary outcomes included rate of PSA testing and results of a post-visit phone survey assessing patients perception of their participation in the decision making, patient knowledge of PSA testing, the control preferences scale, and acceptability of the flyer. Additionally, clinicians seeing patients in the intervention arm were randomized to receiving a reminder to

discuss PSA screening prior to the visit or no intervention. Chi-Squared analysis was used to evaluate differences between the groups.
RESULTS: There were no differences in chart documentation of PSA discussions (17.6% in the flyer group vs. 13.7%, p=0.36) or the rate of PSA testing (62.5% vs. 58.5%, p=0.49). When clinicians were reminded to discuss the PSA test with their patients, there was a non-significant trend toward patients receiving more testing (72.9% vs. 55.4%, p=0.06). Response rate for the follow-up survey was 53.7% (55.2% in the intervention and 53.0% in the control). Of those patients who reported having received the flyer in the survey, significantly more reported having a discussion around PSA testing with their provider (91.5% vs.57.1%, p<0.001) and reported sharing their feelings surrounding PSA testing (83.0% vs 56.7%, p=0.002). Patients who reported receiving the flyer generally scored better on knowledge questions regarding PSA testing, but this difference was significant for only one of the questions:85.1% vs. 68.6% knew that the PSA test is conducted by a blood sample (p=0.003). The majority of patients preferred an active role in decision making, reporting that the decision should be made either the patient alone (19.7%), by the patient with providers input (32.2%), or by the patient and provider together (40.8%), with similar responses between the groups. Of those who received the flyer, 89% would recommend it to others.
CONCLUSION: Patients who reported receiving the flyer had more discussions with their provider and expressed more of their feelings around PSA testing. Additionally, the flyer improved

knowledge around PSA testing and was highly acceptable to the patients. However, it had no effect on the rate of PSA testing or the rate of documentation of discussions surrounding PSA testing. Interestingly, reminding the provider to discuss PSA testing resulted in a higher rate of PSA testing. Improving patient participation in PSA decision making is important regardless of the rate of PSA testing.
LITERACY-COMPENSATORY STRATEGIES AND RESOURCES OF OLDER LATINOS WITH DIABETES
Kristina M. Cordasco 1; Gery Ryan 2; Blanca X. Dominguez 2; Alexis Huynh 2; Diana C. Homeier 3; Kathyrn Pitkin Derose 2; Catherine A Sarkisian4. 1The VA Greater Los Angeles Health Care System; The RAND Corporation; The University of California, Los Angeles, Los Angeles, California ; 2The RAND Corporation, Santa Monica, California ; 3LAC + USC Medical Center, Los Angeles, California ; 4The VA Greater Los Angeles Healthcare System; The University of California, Los Angeles, Los Angeles, California . (Tracking ID # 11105)
BACKGROUND: Limited health literacy is associated with multiple health disparities. As a foundation for developing patient-centered interventions to decrease these disparities, we identified literacy-compensatory strategies and resources used by older Spanish-speaking Latinos with diabetes and limited health literacy.
METHODS: We conducted semi-structured interviews with monolingual Spanish-speakers who were illiterate (Shortened Test of Functional Health Literacy, sTOFHLA=0), very low literate (sTOFHLA score=18), or limited health literate (sTOFHLA score=916); aged 65 years or more; patients of The Los Angeles County + University of Southern California Medical Center primary care clinics; had visual acuity 20/100; and diagnosed with diabetes for 1 or more years. We asked participants to describe how they manage the prevention, monitoring, responding, and communicating tasks associated with diabetes self-management (Table). All interviews were professionally
translated and transcribed. Using content analysis, two team members (K.C. and B.D.) read the first 30 transcripts and then jointly listed and discussed themes of reported literacy-compensatory strategies and resources. After serially testing these themes against 6 intentionally-selected test transcripts, we presented them to the entire research team. Through discussion, the team further developed and clarified theme definitions. We then reviewed the remaining transcripts and labeled participants statements that illustrated these themes. Transcripts and labeling were managed with Atlas.ti6.0.

RESULTS: Of the 91 participants, 23% were illiterate, 43% were very low literate and 34% had limited health literacy. Participants described using a range of strategies and resources for acquiring information, organizing information and acting on tasks. Strategies can be broadly classified as those in which the participant retains complete control for caring for their health, those in which the participant shares control with others, and those in which the participant relinquishes control to others. Those participants who retain complete control in managing their disease compensate for their literacy deficits by relying on alternative skills, such as memory, and procuring assistance from a variety of resources, including healthcare personnel, neighbors, and available strangers. A second category of participants share control with family members, consistently utilize one or two family-members as their resource when faced with literacy-dependent tasks. In a third category, some patients completely relinquish control of their health to others, so that a caregiver performs all tasks related to the participants health.
CONCLUSION: Older illiterate, low-literate, and limited health literate patients use a range of strategies and resources to compensate for their literacy limitations. Future work should examine if certain strategies and resources are more effective than others, potential determinants of effectiveness, and how interventions can be synergistic with patients strategies and resources.

BLOOD PRESSURE CONTROL IN A HIGH PERFORMING HEALTH-CARE SYSTEM: ARE WE OVERTREATING? Eve Kerr 1; Michelle Lucatorto 2; Rob Holleman 3; Leonard Pogach 4; Mary Hogan 3; Sarah Krein 1; Steven Bernstein 1; Timothy Hofer1. 1VA Center for Clinical Management Research and University of Michigan, Ann Arbor, Michigan ;
2VA Office of Quality and Performance, Washington DC, District of Columbia ; 3VA Center for Clinical Management Research, Ann Arbor, Michigan ; 4Center for Healthcare Knowledge Management, East Orange, New Jersey . (Tracking ID # 11107)
BACKGROUND: In response in part to rigorous performance measurement, the Veterans Health Administration (VHA) and other high-performing healthcare systems have seen dramatic improvements over the past decade in the proportion of diabetic patients whose blood pressure (BP) is less than 140/90 mm Hg. However there is increasing concern that performance measures may also be motivating overtreatment of hypertension, resulting in dangerously low diastolic levels. In collaboration with clinical and research experts in hypertension, we have developed a tightly-linked clinical action measure, which is designed to encourage appropriate clinical action while minimizing unintended consequences like overtreatment; and a measure of potential overtreatment, designed to monitor for overly aggressive treatment in the face of low diastolic BP. We applied these measures to examine what proportion of VA diabetic patients are meeting appropriate quality for hypertension and the degree of potential overtreatment. METHODS: Using data from the national corporate data warehouse, we examined the proportion of diabetic Veterans passing a linked clinical action measure for hypertension between July 2009 and September 2010. The index BP was the last BP recorded prior to July 2010. Passing the

measure was defined as: having an adequate index BP at the visit (BP<140/90; or SBP <150 with either a low diastolic (<65) or on >=3 moderate dose BP medications) or having an appropriate action within 90 days of the index BP (BP medication intensification or repeat BP <140/90). We also examined overtreatment, defined as having an index BP <140/65 and either BP medication intensification within 90 days or being on >=4 BP medications at moderate or high dose. Variability across facilities was assessed using multilevel logistic models.

RESULTS: 696,504 diabetic patients in 129 facilities were eligible. Overall, 93% passed the linked action measure: 81% because they had a BP <140/90 at the visit; and an additional 12% with BP >140/90 who passed on the basis of BP <150/65(1%), SBP <150 on >=3 medications (2%), medication intensification (8%) and repeat BP <140/90 (1%). Facility pass rates varied significantly but over a limited range from 90% to 96% (p<.001). 144,264 patients (20%) had a BP <140/65; of these, 25% had potential overtreatment (21% were intensified, 4% were on >=4 medications). Facility rates of potential overtreatment varied from 21% to 30% (p<0.001). Facility rates of potential overtreatment varied from 21% to 30% (p<0.001). Facilities with higher rates of overtreatment had:(1) higher rates of meeting a stringent (and not promoted in VHA) BP control level of 130/80(p<0.05); and (2) higher proportions of patients on 4 or more antihypertensive agents (p<0.001).
CONCLUSION: Over 90% of diabetic Veterans are receiving appropriate hypertension care, as indicated by a linked clinical action measure, with moderate variation across facilities. Rates of potential overtreatment varied widely across facilities and were associated with higher facility rates of meeting stringent control levels and with complicated drug regimens. Our results show that overall rates of potential overtreatment are currently approaching the rate of under-treatment (5%-7%) and suggest that monitoring and reducing overtreatment may now be equally important for improving quality of care in VHA and possibly in other high performing healthcare systems.

FACTORS INFLUENCING QUALITY OF LIFE IN LATE LIFE DISABILITY Alexander Smith 1; Jennifer King 1; Lindsey Yourman 1; Cyrus Ahalt 2; Catherine Eng 1; Sara Knight 1; Eliseo J Perez-Stable 1; Kenneth Covinsky1.
1UCSF, San Francisco, California; 2SFVAMC, San Francisco, California. (Tracking ID # 11110)

BACKGROUND: While late life disability is widely assumed to negatively impact quality of life, factors influencing quality of life of elders with late life disability have not been well described. We therefore conducted a study of quality of life in a diverse population of elders with late life disability. METHODS: We used qualitative methodology. Subjects were recruited from On Lok, the first Program of All-inclusive Care for the Elderly (PACE). All On Lok enrollees are disabled and meet Medicaid criteria for nursing home placement. Average life expectancy is 4.5 years following enrollment. We interviewed elders in English, Spanish, and Cantonese who had a mini-mental status >20. Respondents were asked to rate their overall quality of life on a 5 point scale (excellent to poor). Open ended questions explored the reasons for their rating, with specific probes about living with disability and dependence. Responses were taped and transcribed. Transcripts were analyzed using grounded theory methodology. Codes were grouped into themes. Recruitment stopped when no new themes emerged.
RESULTS: We interviewed 60 older adults (mean age 78, 62% women, 27% European American, 23% African American, 12% Latino, 37% Chinese American, mean 3 ADL dependencies). 76% of respondents rated their quality of life as good or better. 6 domains emerged that dependent elders felt were important to their quality of life: physical (disability, pain, non-pain symptoms); psychological (depression, anxiety, resilience); cognitive (cognitive impairment); ethical (autonomy, dignity); spiritual/religious (hope, religious coping); and social (life-space, isolation/support). Examples of representative quotes include: It is unfortunate that a lot of your family or other people feel that once you are old you do not know anything anymore and you justkind of in the way (dignity: deserving of respect or esteem); Before I could take the bus to go out but last year since I fell until now I am too afraid to go out on my own (life space: ability to function and participate in society). CONCLUSION: In

this diverse group of very disabled elders, most rated their quality of life as at least good. Many of the factors that influence quality of life, including life-space, resilience, religious coping, and respect for dignity, are missing from standard assessments of quality of life (e.g. SF-36).

RESPECT THE WAY I NEED TO COMMUNICATE WITH YOU: HEALTHCARE EXPERIENCES OF ADULTS ON THE AUTISTIC SPECTRUM Christina Nicolaidis 1; Dora Raymaker 2; Katherine McDonald 3; Elesia Ashkenazy 2; Sebastian Dern 4; Cody Boisclair 5; Amanda Baggs 6; Enyinne Ejiasa 1; Roberta Delaney 7; Way Rhonda8.

BACKGROUND: It in now estimated that up to 1% of the population may be on the autistic spectrum, but little is known about how to provide quality primary care to autistic adults. Our online survey research has found that autistic adults who use the Internet have statistically significant worse healthcare outcomes than non-autistic Internet users. The objective of this qualitative study was to obtain an in-depth understanding of autistic adults experiences with healthcare and recommendations for improving care.

METHODS: The Academic Autistic Spectrum Partnership in Research and Education (AASPIRE) is a partnership between researchers, autistic self-advocates, family members, healthcare workers, and disability service providers. We used a Community Based Participatory Research (CBPR) approach were community members served as equal partners in every stage of the project. We conducted semi-structured, open-ended, in-depth interviews via telephone, email, or instant messenger chat, with adult Internet users who considered themselves to be on the autistic spectrum. Participants had to reside in the US and either carry a formal medical diagnosis on the autistic spectrum or score 32 or greater on the Autism Quotient. We purposefully sampled participants from our earlier online survey to ensure diverse demographic characteristics, diagnosis type, age of diagnosis, preferred communication mode, and healthcare utilization and satisfaction. Interview questions addressed participants positive and negative experiences with healthcare and their recommendations for improving care. Academic and community partners jointly analyzed data using thematic analysis with an inductive approach (consistent with Grounded Theory), at a semantic level with an essentialist paradigm.

RESULTS: 27 autistic Internet users (12 men and 15 women), aged 20 64 years, participated in an individual interview. 63% were White, non-Hispanic. While education levels were high (88% with at least some college), the majority of the participants were unemployed and had a personal income of less than $25,000. We identified five common themes. 1) Difficulty with body awareness can affect ability to report symptoms: I dont know my own body. So when I feel all these different sensations, everywhere, I dont know which is the real problem and which is just sensation. 2) Preference for written communication is not always respected by physicians: I prefer and find it easier to communicate in text But with every doctor I speak to, they wave away the note-card and look at me to ask the same question I have just answered. 3) Difficulty with open-ended questions or vague explanations: BAD: How do you feel? Too vague. 4) Sensory issues can cause difficulty interacting with provider: All of the sensory input makes my brain slow down.... I am not able to bring up my concerns because it is all I can manage to figure out what the doctor is saying so I can respond to his questions. 5) Difficulty with executive function affects ability to navigate health system: With my autism it is very difficult for me to understand and follow all the different appointments and procedures I have to schedule.... No one will help me since apparently people magically become competent at these things before they turn 21. Participants offered

many concrete suggestions for how providers can help improve healthcare interactions with autistic patients. Examples included asking specific, closed-ended questions, allowing patients to communicate in writing, allowing time for patients to process information, and reducing unnecessary sensory stimuli.
CONCLUSION: Autistic adults describe important factors that may adversely affect the health and healthcare of patients on the autistic spectrum and offer concrete ideas of how to improve care. Healthcare providers should be open to accommodations and strategies that may improve interactions with autistic patients, and thereby positively impact health outcomes. We are using information from this study to create interactive tools to improve the primary care of adults on the autistic spectrum.
USE OF COMPLEMENTARY AND ALTERNATIVE MEDICINE AMONG PATIENTS WITH END-STAGE RENAL DISEASE Gurjeet Singh Birdee 1;
Kerri Cavanaugh 1; Russell Rothman 1; Talat Alp Ikizler 1; Russell S Phillips2. 1Vanderbilt University, Nashville, Tennessee; 2Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 11120)
BACKGROUND: Few studies have examined the use of complementary and alternative medicine (CAM) among patients with chronic kidney
disease including end-stage renal disease (ESRD). Mind-body practices, one type of CAM modality, may be a novel therapeutic option for patients with ESRD during dialysis. Examples of mind-body practices are breathing exercises, meditation and yoga. The purpose of this study was to identify the frequency of CAM use, perceptions of mind-body practice, and willingness to learn mind-body practices among patients with ESRD receiving in-center hemodialysis.
METHODS: Adult patients with ESRD on hemodialysis were surveyed at a dialysis center affiliated with an academic medical center in Boston, MA from September 2009 to July 2010. We queried patients regarding: use of 18 common CAM modalities and dietary supplements in their lifetime and the last month; perceived importance of mind-body interaction for health (Likert scale 010 for none to extremely important); and willingness to learn mind-body practices during hemodialysis. Data were analyzed using descriptive statistics for CAM use and bivariate analyses based on demographics including age, sex, race, and dialysis vintage. CAM therapies were grouped into categories based on conventional definitions according to the National Center for Complementary and Alternative Medicine: 1. biologically based practices (e.g. herbs); 2. manipulative/body based practices (e.g. chiropractic); 3. mind-body based practices (e.g. meditation); and 4. alternative medical systems (e.g. homeopathy). Continuous variables are reported as medians and inter-quartile range (IQR), and categorical variables as frequencies. Categorical variables were compared using Fischers exact test.
RESULTS: Among 106 eligible subjects, 89 subjects completed the survey (response rate 84%); 53% were male, 61% black, and their mean age was 62 years. More than half of patients (61%) reported using CAM for health in their lifetime. Among all subjects, the most frequent CAM modalities used in their lifetime were mind-body practices (42%) and manipulation and body-based practices (34%). The most common mind-body practices used were deep breathing exercises (27%), meditation (26%), and yoga (11%). Overall lifetime CAM use was similar among patients with regards to gender, race, and dialysis vintage. In the last month, 36% of patients reported using CAM for health. The most common CAM modalities used in the last month were mind-body practices (27%). Subjects reported that mind-body interactions were very important to health with a median score of 9 (ICQ: 5,10). A majority of patients reported interest in learning mind-body practices (70%) and participating in a mind-body study during dialysis (75%). Of patients who had used mind-body practices in their lifetime, a large majority reported interest in participating in a mind-body study during dialysis (87%). In addition, a majority of patients who never used mind-body practices also reported interest in participation (65%).
CONCLUSION: CAM use, particularly mind-body practice, is frequent among patients with ESRD on hemodialysis. Most patients on hemodialysis perceive mind-body interactions as very important for health and are interested in learning mind-body techniques during dialysis. Mind-body therapies may be a feasible therapeutic intervention for patients with ESRD. Further research to develop and evaluate mind-body therapies

in this population is warranted.

WERE NOT GOING THERE: AN ANALYSIS OF PATIENT-PROVIDER COMMUNICATION ABOUT NARCOTIC ANALGESIA FOR CHRONIC NON-MALIGNANT PAIN Helen Kinsman 1; Todd Korthuis 2; Somnath Saha 2; Victoria Sharp 3; Jonathan Cohn 4; Richard Moore 1; Mary Catherine Beach1. 1The Johns Hopkins University School of Medicine, Baltimore, Maryland ; 2Oregon Health &Science University, Portland, Oregon ; 3St. Lukes-Roosevelt, New York, New York ; 4Wayne State University School of Medicine, Detroit, Maryland . (Tracking ID # 11121)

BACKGROUND: Pain is a presenting symptom in over 80% of office visits, and chronic pain affects more Americans than diabetes, CHD,

and cancer combined. Patients in pain often seek pharmacologic relief, making analgesics the most frequently discussed therapeutic drug in outpatient visits. Anecdotally, negotiations about narcotic analgesics in this setting are frustrating for patients and providers. We conducted this study to better understand patient-provider communication about narcotic analgesia for chronic nonmalignant pain.

METHODS: We audio recorded 45 HIV providers interacting with 418 of their patients in routine outpatient encounters at four sites (Baltimore, Detroit, New York, and Portland) in the Enhancing Communication and HIV Outcomes (ECHO) Study. We transcribed each visit and used 20 narcotic-related search terms to identify transcripts containing conversations about narcotic analgesics. Through qualitative analysis of each encounter, we developed and applied a coding scheme to describe key features of this dialogue.

RESULTS: Providers had a mean age of 44.5 years, and were mostly female (58%) and white (69%). Patients had a mean age of 45.4 years, 66% were male, 58% were African American, and 34% had known their HIV provider for more than 5 years. Out of 418 encounters, 130 contained at least one narcotic-related search term. Of these, 48 encounters (11% of total) were found to contain substantive discussion of narcotic-related pain management. The most common causes of pain were musculoskeletal/back (31%) and neuropathic (17%); in 29% of encounters, the cause of pain was never mentioned. Most narcotic conversations were initiated by patients (58%), while providers more often ended the conversation (74%), sometimes abruptly (e.g. P:The end of the night, where I sleep, my back hurt me real badthats when I take the Percocet and D:Let me ask a quick question for ya P:Uh Huh D:When was the last time you had a flu shot?). In almost half of the encounters, providers verbalized concern about the narcotic regimen (46%), and suggested alternative therapeutic options (48%). A third of encounters (33%) contained dialogue suggesting a difference of opinion or conflict (P:I cant just stop takin em. D: Why? P: What do you want me to do, go crazy? D: You could slow down. Say go from four to three. P: Uh uh. I just want my regular prescription what you all been giving me every month). Fewer than half of providers (42%) explicitly acknowledged the patients experience of pain. Providers more often offered/agreed than refused/disagreed to give the prescription (50% vs. 23%), sometimes reluctantly (Ill give you a little bit of oxycodone but you need to get off that, okay?). However, in 27% of encounters, no decision seemed to be made about the issue.

CONCLUSION: Pain management discussions are relatively common in routine outpatient HIV encounters and are characterized by provider avoidance suggestive of ambivalence or discomfort, as well as patient-provider conflict. Further research and attention to this particular communication challenge is needed to determine and teach optimal communication about narcotic medications for chronic nonmalignant pain.

VARIATIONS IN DIABETIC OUTCOME MEASURES ACROSS LANGUAGE GROUPS FOLLOWED ATAN IMMIGRANTAND REFUGEE CLINIC Xiaoxue Huang 1; Tracy Boyd 1; Susan Onstad 1; Anita Leake 1; Azeb Gebrekidan 1; Rahel Habtemichael 1; Vi Le 1; Mona Mussa 1; Carey Jackson1. 1University of Washington, Seattle, Washington. (Tracking ID # 11122)

BACKGROUND: The Institute of Medicines (IOM) report on health disparities, Unequal Treatment, identified the medical systems inability to distinguish minority groups with meaningful specificity as a primary barrier to

recognizing critical disparities in health care and outcomes. A recent follow-up report on Race, Ethnicity, and Language Data called for more detailed demographic data collection. Hospitals have historically identified patients according to five federal categories (Black/African American, White, Asian/Pacific Islander, American Indian/Alaska Native and Hispanic/Latino) and other. These may miss
important language, literacy and ethnic variations in quality of care across groups, particularly those for whom English is a second language. This study evaluated the validity of self-reported primary language to detect disparities in diabetes care across language groups of first generation, mostly non-English speaking outpatients at an international clinic.
METHODS: The REALL (Race, Ethnicity and Language proficiency Level) study is across-sectional pilot study, surveying a convenience sample of immigrant and refugee patients receiving primary care at an urban, county hospital. REALL participants were eligible for this study if they had diabetes based on medical record data using a standard hospital quality improvement protocol and completed the REALL survey question about how many and what languages they speak, their reading ability in those languages, including English, and the culture they most identify with. Survey data were linked with medical record data that included hemoglobin A1C (HA1C), low density lipoprotein (LDL) and systolic blood pressure (SBP). Diabetes control was evaluated across the 6 largest language groups.
RESULTS: A total of 640 patients were surveyed and no one refused. 250 patients were diabetics and eligible for the study (51.5% of all diabetic patients in the clinic). Common language groups were Vietnamese (n=60), Somali (42), Cambodian (31), Amharic (30), Chinese(23), Tigrinya (19) and other (45, representing 22 smaller language groups). The survey data were 90.84% concordant with registration data for primary language (kappa=0.895). Mean HA1Cs were lowest among Vietnamese patients (7.24, 95%CI 6.88-7.60), significantly lower than Somali patients (8.43, 95%CI 7.88-8.98, p=0.0003) and Cambodian patients (7.89, 95%CI 7.35-8.43, p=0.038). While 52% of Vietnamese patients had HA1C <7, only 26% of Somali patients had HA1C <7 (p=0.015). There were no statically significant differences across language groups in mean LDL level or SBP.
Limitations: These are preliminary results that reflect a clinic sample that only cares for immigrants and refugees, which may not reflect population samples or other clinical experience. This study is ongoing, the number and percentage of eligible diabetic patients are expected to increase to almost double.
CONCLUSION: Results suggest that there is variability in diabetic outcomes across language groups in first generation immigrant communities. The observed differences may reflect aspects of relocation to the US not yet understood. Somalis are the most recently arrived refugee community, thus the least acculturated, least established and potentially most stressed of all immigrant communities in this study. Further inquiry into length of time in the US, length of time established in clinical care and qualitative work on dietary practices are warranted.
ASSESSING AFRICAN AMERICAN CONGREGATION MEMBERS READINESS TO PARTICIPATE IN RESEARCH Adebowale Ayoola Odulana 1; Mimi Kim 2; Yhenneko Taylor 3; Melissa Green 2; Moses Goldmon 4; Paul Godley 2; Shelly-Ann Meade 5; Carlton Boyd 6; Daniel Howard 7; Giselle Corbie-Smith2. 1Univeristy of North Carolina at Chapel Hill Cecil G. Sheps Center for Health Research, Chapel Hill, North Carolina ; 3College of Health and Human Services University of North Carolina at Charlotte, Charlotte, North Carolina ; 4Shaw University, Raleigh, North Carolina ;
5University of North Carolina at Chapel Hill Department of Epidemiology, Chapel Hill, North Carolina ; 6National Institute of Environmental Health Sciences, Durham, North Carolina ; 7Robert Wood Johnson Foundation Center for Heatlh Policy Meharry Medical College, Nashville, Tennessee . (Tracking ID # 11123)
BACKGROUND: Church based research has increasingly become a strategy for involving African Americans in research efforts to reduce

health disparities. While the role of the pastor and the church environment has been noted to be critical to the success of these efforts, few studies have independently evaluated African American church/pastor characteristics and congregant characteristics as organizational and individual constructs respectively, as they relate to attitudes towards research participation. In this study, we assessed the organizational and individual readiness of African American congregants to participate in research.
METHODS: We surveyed adult members of 11 predominately African American churches, all in regions with a high density of African Americans and significant health disparities. Respondents were asked to share their attitudes regarding research participation, and how willing, ready, and confident they were about participation; pastors were also surveyed and matched individual congregants through church identifier. The main outcome measure, the readiness index score, summed responses across the 3 domains (i.e. willingness, readiness and confidence in research participation). We constructed a series of logistic generalized estimating equations to adjust for clustering and to assess the independent contributions of church/pastor characteristics and respondent characteristics, to congregants readiness to participate in research.
RESULTS: Of the 1094 respondents, (response rate 83%) 72% were female, 57% were age 50 or older, 82% had at least a high school education, and 50% reported 2 or more health conditions. In surveyed churches, 79% had male pastors, 52% had a pastor age <45, and 97% had a pastor with a high school education or higher. Respondents who were concerned about paying for healthcare were more willing (1.55 CI1.16-2.08), ready (OR 1.43 1.14-1.80), and confident (1.77 CI 1.39-2.25) about research participation. Churches with younger pastors (age <45) had members who felt ready (OR 1.32 CI 1.16-1.50) and confident (OR1.91 CI 1.63-2.23) to participate in health research when controlling for respondent characteristics. Churches with a pastor with at least a high school education were confident (OR 2.49 CI 2.10-2.94) regarding research participation. Pastor age less than 45 (OR 1.28; CI 1.07-1.54) and higher pastor educational attainment (OR 1.56; CI 1.28-1.89) were independently associated with a congregants higher readiness scores. After controlling for these church level characteristics congregants concern about paying for health care (OR 1.53; CI 1.24-1.89) was the only individual characteristic that was associated with higher readiness scores.
CONCLUSION: Characteristics of the church leadership were significantly associated with congregant readiness for research participation, a finding that highlights the importance of the church context in relation to individual decisions regarding research participation. Church based research strategies that prioritize establishing commitment and buy in on an organizational level when conducting research may prove vital to acquiring and sustaining access to underrepresented African Americans.
PHYSICIANS ATTITUDES ABOUT RECOMMENDING SURGERY FOR EARLY STAGE LUNG CANCER AND POSSIBLE REASONS FOR TREATMENT DISPARITIES Samuel Cykert 1; Franklin McGuire 2; Paul Walker 3; Michael Monroe 4; Giselle Corbie-Smith 5; Peggye Dilworth-Anderson 5; Lloyd Edwards5. 1University of North Carolina, Chapel Hill, Chapel Hill, North Carolina ; 2USC School of Medicine, Columbia, South Carolina ; 3ECU Brody Medical School, Greenville, North Carolina ; 4Carolinas Medical Center, Charlotte, North Carolina ; 5UNC-CH, Chapel Hill, North Carolina . (Tracking ID # 11126)
BACKGROUND: Multiple reports have shown double digit gaps in lung cancer surgery rates for African-American patients (AA) with early stage disease compared to Whites (W). Physician attitudes could potentially influence the framing of surgical decisions and contribute to this disparity in care. As part of a recent prospective cohort study to examine possible causes of decisions against lung cancer surgery and lower surgical rates for African-Americans, we performed a companion survey of physicians caring for lung cancer patients.
METHODS: Using pulmonary, oncology, thoracic surgery, and generalist practices in 5 communities, we enrolled 437 newly diagnosed patients with early stage, non-small cell lung cancer. Inclusion criteria were as follows: patients were required to be at least 18 years old, have a tissue diagnosis or >60% probability of non-

small cell lung cancer using Bayesian methods, and be limited to Stage I or II disease by clinical and radiological testing. Patients were identified from direct referral from practices or through the utilization of a chest CT review protocol. After being informed of the diagnosis of probable or definite lung cancer, but before the establishment of a treatment plan, patients were administered a 100-item survey. We asked patients to identify the physician who had provided the most information about his or her lung cancer care. After informed consent was obtained, physician participants completed a 93-item survey that included statements followed by Likert-type response scales to assess attitudes about lung cancer communication, reasons for recommending against surgery, and possible causes of black-white treatment disparities.
RESULTS: One hundred physicians were identified by participating patients. Eighty-four completed the questionnaire. The median age of respondents was 45 yrs and 73% were W, 11% Asian, 7% Hispanic, and 5% AA. 48% practiced in academic settings while the remainder practiced in community settings. 20% were thoracic surgeons, 40% pulmonologists, 16% oncologists, and 20% were general internists. All respondents believed that comorbid illnesses were important in recommending against surgery with 76% regarding these as extremely important. 36% felt that patients deemed non-compliant should not go to surgery while 21% agreed that lower compliance was a reason that AA underwent surgery less. The percentage of respondents who felt that the following factors were important in recommending against surgery were: 51% difficult communication, 46% fear of surgery, 46% disbelief in diagnosis, 76% lack of social support, and 23% financial barriers. Percentages of agreement for specific reasons that AA do not receive surgery as often as W were: 23% difficult communication, 34% fear of surgery, 25% disbelief in diagnosis, 26% lack of social support, and 48% financial barriers.
CONCLUSION: The wide range of acceptable reasons for physicians recommendations against lung cancer surgery and their correlation with perceptions of why African-American patients do not go to surgery as often highlight the potential contribution of subjective decision making to disparities in cancer care. The connection of these attitudes to actual recommendations and outcomes requires further investigation.
PROMOTING ADVANCE CARE PLANNING IN PATIENTS WITH CANCER WITHOUT DIMINISHING HOPE OR RAISING ANXIETY: AN INTERACTIVE COMPUTER-BASED DECISION AID Michael Jay Green 1; Jane R Schubart 1; Elana Farace 1; Erik B. Lehman 1; Megan Whitehead 1; Benjamin H Levi1. 1Penn State College of Medicine, Hershey, Pennsylvania. (Tracking ID # 11127)
BACKGROUND: Despite agreement that patients with advanced cancer ought to prepare for the future, most do not complete advance directives (AD), and even when they do, physicians often disregard the AD documents at key moments. Among the many reasons for this disregard are concerns that: 1) addressing the topic of advance care planning would diminish patients hope and raise their anxiety, and 2) lack of knowledge undermines patients ability to meaningfully complete AD

documents that physicians can trust. We developed an interactive computer-based decision aid to help people clarify and articulate their medical treatment preferences in the event they become unable to speak for themselves. The purpose of this study was to determine whether use of the decision aid by patients with advanced cancer would increase their knowledge of advance care planning without diminishing hope or increasing anxiety. The study was sponsored by the American Cancer Society and this in an interim analysis of results.
METHODS: We conducted a randomized controlled trial of advance care planning methods using standard advance directive materials vs. a computer-based decision aid (Making Your Wishes Known: Planning Your Medical Future). Patients with advanced cancer (stage 4 disease and life expectancy <2 years) were recruited from clinics in oncology, surgery, and radiation medicine at a mid-Atlantic academic medical center. Participants were randomly assigned to Control or Intervention Groups, and completed pre/post measures of anxiety (STAI) hope (Herth Hope Index), and knowledge (27 items). Changes in group mean scores from baseline to post-

intervention were compared using a repeated measures mixed model adjusted for the baseline measure.
RESULTS: 139 individuals were enrolled and 138 completed the protocol (mean age 61 years, range 2287; 39% female; 96% white; 52% with lung, breast, brain or liver cancer; 84% own their own computer). There were no demographic differences between groups. Baseline anxiety was low in both groups (mean=30 in Control and 29 in Intervention Group, where 20=low anxiety and 80=high anxiety), and did not increase significantly after advance care planning. Similarly, hopefulness was high (mean=41 in both groups, where 12=low hope and 48=high hope) and did not diminish after advance care planning. Knowledge scores increased in both groups, but significantly more ($p<0.01$) in the Intervention Group than the Control Group (13% vs 3%). Finally, participants in the Intervention Group expressed significantly greater mean satisfaction with the advance care planning method than those in the Control Group ($p=0.03$).
CONCLUSION: In this interim analysis, use of our decision-aid for advance care planning resulted in greater knowledge without increases in anxiety or decreases in hope. These findings counter concerns raised by some physicians about the benefits and risks of advance care planning.
USING UNANNOUNCED STANDARDIZED PATIENTS TO ASSESS QUALITY OF CARE: CHARTING AND OUTPATIENT SAFETY Sondra Zabar 1; Angela Burgess 1; Kathleen Hanley 1; David Stevens 2; Jessica Murphy 3; Mack Lipkin 1; Adina Kalet 4; Colleen Gillespie7. 1NYU School of Medicine, New York, New York ; 2Gouverneur Healthcare Services, New York, New York ; 3Governeur Healthcare Services, New York, New York ; 4NYU School of Medicine, NY, New York . (Tracking ID # 11137)
BACKGROUND: Accurate charting is critical to outpatient safety and yet little is known about residents completeness and accuracy in documenting the care they provide. Unannounced Standardized Patient (USP) can assess what residents do when behaving spontaneously in real practice. USP visits are used in this study to explore the degree to which residents may be over- or under-documenting or failing to document important information in the right place. In addition, we use chart data from these standardized clinical scenarios to explore the degree to which residents vary in their practices.
METHODS: 15 internal medicine residents each saw four Unannounced SPs (USP) over 6-months in their urban, outpatient, continuity practice. The 4 cases were new visits and reflected chief complaints and patient demographics common to this primary care practice. Neither clinic staff nor the residents knew which patients were actors; residents had been informed and consented that USPs would be introduced to the clinic during a 6-month period. After each visit, the highly trained USPs completed a comprehensive checklist and rating form and residents entered their notes believing these to be actual patients. The electronically charted notes for these visits (n=60) were then collected and abstracted. Core variables for these analysis included degree of correspondence between the chart and USP-report of 12 physical exam procedures in two relevant USP cases (over- or under-documentation); documentation of allergies in the chart field used as a fail-safe against prescription errors (documenting in the right place); and rate of variation in residents ordering of labs and scheduling of next visits.
RESULTS: The overall detection rate of the USPs was approximately 38% (23 of first 60 visits) and varied across USP cases (14%; 47%; 31%; 71%, $p=.014$). There was complete or almost complete (<10%) agreement between the chart and the USP-report for 7 of the 12 physical exam procedures assessed. In 5 instances there was substantial over- or under-documentation: over-documentation was present in all 5 procedures (extremities 27%, neurological 20%, vitals 13%, heart 20%, and abdomen 20%) and two procedures involved both over- and under-documentation (extremities, vitals). In the one case involving allergies (if asked, the USP reported PCN allergy), while 88% of the residents charted the PCN allergy, only 29% noted it in the correct chart field (used by the pharmacy system to prevent prescription error). Residents ordered 78% of the labs deemed essential (SD 9%); 6/16 residents ordered <75% of essential labs. There was substantial variation in residents scheduling of next visits: across all four cases, most next visits were scheduled for 1 month (4053% depending on the case); however 7% to 27% of visits, depending on the case, were PRN; 1333% of visits were for less than 1 month

(from 2 days to 3 wks); and 727% were for more than 1 month (from 2 months to 1 yr). CONCLUSION: USP methodology is a feasible, practical way to assess actual resident behavior in clinical practice. Residents tend to over-document physical examination procedures. While residents documented allergies, most did so in the wrong place, with serious implications for patient safety. Follow-up practice (labs ordered and scheduling of next visits) varied substantially in even in this homogeneous resident physician population, especially striking given the standardized encounters. USP visits provide valuable insight into the accuracy of residents charting as well as the amount of resident-driven variation in practice, both of which are clearly determinants of patient safety.
DECISIONS OF CLINICIAN EDUCATORS TO ENCOURAGE ROUTINE HIVSCREENINGAMONGTRAINEES
Gail Berkenblit 1; Philip Korthuis 2; Michael Bass 3; Hirut Gebrekristos 4; Joseph Cofrancesco 5; Lynn Sullivan 6; Robert Cook 7; Marcia Edison 8; Philip Bashook 3; James Sosman9. 1Johns Hopkins University, Baltimore, Maryland ; 2Oregon Health and Science University, Portland, Oregon ; 3University of Illinois College of Medicine, Chicago, Illinois ; 4Johns Hopkins School of Public Health, Baltimore, Maryland ; 5Johns Hopkins Hospital, Baltimore, Maryland ; 6Yale, New Haven, Connecticut ; 7University of Florida, Gainesville, Florida ; 8University of Illinois, Chicago, Illinois ; 9University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin . (Tracking ID # 11138)
BACKGROUND: CDC recommendations for routine, voluntary HIV screening of all Americans age 1364 have been slow to be adopted. One method to increase adherence to clinical practice guidelines is through medical school and residency training. The purpose of this study was to explore clinician educator (CE)s attitudes, barriers, and behaviors regarding routine HIV testing.
METHODS: We conducted a subgroup analysis of CEs who responded to a 2008 survey of general internists who were active

SGIM members. Members were asked about their outpatient practices, knowledge and attitudes regarding the revised CDC guidelines, their role in trainee education, HIV testing practices and whether they encouraged trainees to perform routine HIV screening. Survey items were adapted from focus group findings and pilot tested among potentially eligible participants. Knowledge of the guidelines was rated as optimal (5 of 5 guideline questions answered correctly), high (>3 of 5 answered correctly) or low (<3 answered correctly). Positive attitudes were measured by agreement with statements that testing would benefit patients, improve public health, and/or not interfere with other medical needs. Associations between HIV testing knowledge and attitudes and encouraging trainees to perform routine screening were estimated using bivariate and multivariate logistic regression.
RESULTS: Of 1,592 active members approached, 515 (32%) responded to the survey. Of these, 367 (71%) indicated they supervised trainees in an outpatient general internal medicine clinic. CEs were primarily female (53%), white (76%), and practiced in university-based settings (60%) and communities with estimated HIV prevalence >0.1% (73%). Although both those who supervised residents and those who did not reported high rates of awareness of CDC recommendations (85 and 95%, p=0.22), both had suboptimal knowledge (56% for both groups, p=0.89). Many in both groups reported continued risk-based testing (39 vs 47%, p=0.05). 193 (57%) of CEs reported that they encourage trainees to perform routine HIV testing. CEs who reported screening over 25% of patients in their own clinic were more likely to encourage testing (53% vs 22%, p<0.001). Higher knowledge scores (aOR 5.55, 95% CI 2.3,12.8) and positive attitudes toward testing (aOR 9.77, 95% CI 4.81,19.8) were independently associated with encouraging trainees to screen for HIV. Reasons for not encouraging trainees to perform HIV screening included perceived low local prevalence (37%), competing teaching priorities (35%), and a busy clinic environment (33%). CONCLUSION: Clinician educators have a special role in the dissemination of the CDC guidelines in that they impact the knowledge and attitudes of newly

practicing physicians. Despite awareness of CDC guidelines regarding HIV screening, many CEs do not recommend this practice to their trainees. Those CEs who do encourage testing among trainees have greater knowledge, better attitudes supportive of testing, and report a higher percentage of patients screened. Interventions that improve faculty knowledge of CDC HIV screening guidelines and address barriers to screening in resident clinic may improve medical education regarding routine HIV screening.

COMPARISON OF ROUTINE IMMUNIZATION IN THE GERIATRIC POPULATION AMONG TEACHING, NONTEACHING, AND GERIATRIC AMBULATORY PRACTICES AT A LARGE ACADEMIC MEDICAL CENTER Elisabeth Ihler 1; Rubina Malik2. 1Montefiore Medical Center, New York, New York; 2Montefiore Medical Center, Bronx, New York. (Tracking ID # 11140)

BACKGROUND: Three vaccines are recommended for all geriatric patients: annual influenza vaccine, herpes zoster vaccine at age 60, and pneumococcal vaccine at age 65. However, attainment of universal vaccination has been difficult. There is some evidence that variation in preventive health practices is in part due to clinic factors rather than patient characteristics, with resident clinics faring worse than clinics with similar patient populations staffed by attending physicians and nurse practitioners. To assess this, we investigated differences in administration of these three vaccines between 3 groups of primary care practices operated by Montefiore Medical

Center, including 5 resident teaching practices, 21 nonteaching practices, and one geriatrics practice. We hypothesized that the geriatrics practice would provide the most comprehensive vaccination coverage of the elderly.

METHODS: We compared vaccination practices for the elderly from 20082010 among primary care sites at Montefiore Medical Center. The 21 practices without residents were pooled as the nonteaching group, the 5 teaching sites that included internal medicine and family medicine residents as well as faculty were pooled as the teaching group, and the practice staffed by the geriatrics physicians and fellows was treated as the geriatrics group. The Montefiore Clinical Information System (CIS) was used to select patients for inclusion, collect demographic data (age, gender, race, ethnicity, primary language) and assess vaccination status via vaccine administration recorded in the electronic medication record.

To assess eligibility to receive the pneumococcal vaccine, we identified patients who were seen at least twice in the same practice from 1/1/ 2008 to 1/1/2010, and were at least 65 years old at the time of the first visit in the period. To assess eligibility to receive the herpes zoster vaccine, we identified patients who were seen at least twice in the same medical practice from 5/15/08 (the date of the formal ACIP recommendation) to 1/1/2010, and were at least 60 years old at the time of the first visit. To assess eligibility to receive the influenza vaccine, patients were assessed for both the 20082009 and 20092010 flu seasons. Patients over the age of 65 who were seen at least once in a medical practice between 10/1/08-4/1/09 or between 10/1/09-4/1/10 were included in the influenza groups.

Subgroups of patients with COPD and diabetes were targeted in this study due to medical indications for pneumococcal and influenza vaccination. They were identified using information from ICD-9 codes, electronic problem lists, and laboratory data.

We compared patient characteristics and vaccinations rates between practice sites using chi-square (for categorical variables) or one-way ANOVA (for continuous variables).

RESULTS: There were significant differences between the three practice groups in patient characteristics. The geriatrics group patients were older (mean 79.5 years) compared with teaching (72.8) and nonteaching groups (73.8). In addition, the geriatrics practice had more white and English-speaking patients than the two other groups. The teaching group had the most Hispanic and Spanish-speaking patients. The practices also differed in the prevalence of DM and COPD.

Overall, vaccination rates did not meet national goals in any practice. There were significant differences between practices for influenza vaccination rates for both the 200809 (39.9% nonteaching, 44.5% teaching, and

46.5% geriatrics, p<0.05) and 200910 flu seasons(30.4% geriatrics, 34.0% teaching, 34.7% nonteaching, p<0.05). Rates of pneumococcal vaccine were lowest in the geriatrics practice (25.6%) compared with the teaching (38.5%) or nonteaching (34.0%) practices (p <0.05), In addition, patients with DM received significantly more pneumococcal vaccine than patients without these conditions at the nonteaching (38.2% of diabetics vs 31.7% of nondiabetics) and teaching(41.4% vs 36.4%) groups (p<0.05), but not in the geriatrics group(25.5% vs 25.7%). In both the 200809 and 200910 flu season, patients with DM received more influenza vaccine than nondiabetic patients in all practices (p<0.05). The rates of vaccination with he herpes zoster vaccine were very low across all sites, ranging from0.9% in the geriatrics group to 2.1% in the teaching group (nonsignificant). There were some differences between groups for vaccinated vs. unvaccinated patients for race, ethnicity, primary language and gender but no consistent pattern emerged. CONCLUSION: Overall, vaccination rates in all groups were substantially lower than the 90% coverage that is the national goal, but were

roughly comparable with national vaccination rates for minority patients. There were significant differences between nonteaching, teaching, and geriatrics groups for immunization coverage with all vaccines, as well as for the relationship between chronic disease and vaccination. There was no single practice with overall higher rates of vaccination. The geriatrics groups rates of pneumococcal vaccination for all patients and for patients with DM were surprisingly low, possibly reflecting in part the greater mean age of these patients, who may have received their pneumococcal vaccination after age 65 but prior to the implementation of the electronic medication record in 1997. Pneumococcal and influenza vaccination rates were higher for patients with DM in the nonteaching and teaching groups, but not in the geriatrics patients. This may indicate a greater awareness of age-related vaccination guidelines in the geriatrics practice. Limitations of the study include the thirteen-year limit on vaccination records as well as the inability to identify patients who may have received vaccination at an outside site or who were offered and refused vaccination. The institution of automated reminders for vaccines as part of the electronic medical record may improve vaccination rates in the future.

HEALTHCARE PROVIDERS MISS OPPORTUNITIES TO COUNSEL HIV-INFECTED PATIENTS ABOUT HIGH-RISK SEXUAL BEHAVIOR

Tabor Elisabeth Flickinger 1; Philip Todd Korthuis 2; Somnath Saha 2; Michael Barton Laws 3; Richard Moore 1; Mary Catherine Beach1.
1Johns Hopkins University School of Medicine, Baltimore, Maryland ;
2Oregon Health &Science University, Portland, Oregon ; 3Brown University, Providence, Rhode Island .
(Tracking ID # 11141)

BACKGROUND: Although HIV care guidelines recommend that providers counsel patients about safe sex, HIV-infected patients and providers report that discussion of sexual behavior is infrequent. Using audio-recorded clinical encounters between patients and their providers, we investigated the frequency and content of discussions regarding sexual behavior in HIV care.
METHODS: We performed a cross-sectional analysis of data from two sites of the Enhancing Communication and HIV Outcomes (ECHO) Study. Patients were adults receiving HIV care who presented for routine outpatient follow-up with their provider. Clinical encounters were audio-recorded, transcribed and searched for discussion of patients sexual behavior. We classified the encounters by whether or not the patient reported safe sex, and then according to whether the provider advised a change or maintenance of the recommended behavior (counseling) or not (missed opportunity). When counseling occurred, we further classified the type of behavior change discussed (e.g. condom use). When a missed opportunity occurred, we further classified the type of indication for a counseling session (e.g. diagnosis of STI).
RESULTS: Patients were 62% male, 54% African American, with a mean age of 45.0 (range 2077). Providers were 59% female, 86% white, with a mean age of 42.8 (3057). Of the 223 encounters, discussion of sexual behavior occurred in 92 (0.41, 95% CI: 0.35-0.48). Of these 92 discussions, 11 patients denied sexual activity and were excluded from further analysis. Of the 25 patients who reported safe sex, providers missed

opportunities to reinforce behavior in half of the encounters, 0.56 (0.35-0.76). Of the 56 patients with an indication of unsafe sex, providers missed opportunities to recommend behavior change in three quarters of encounters, 0.77 (0.64-0.87). The most commonly recommended behavior changes were condom use (n=13), disclosure of HIV status (n=5), and reduction in number of partners (n=5). The most commonly missed indications for counseling were STI symptoms (n=20) or STI screening (n=10).

Table 1: Number of encounters with discussion of safe or unsafe sexual behavior in which counseling was received.

CONCLUSION: Discussion of sexual behavior occurred in less than half of HIV care visits. When sexual behavior dialogue occurred, HIV providers often missed opportunities to recommend or reinforce safe sex practices. Further evaluation of barriers to patient-provider communication regarding sexual behavior is indicated to improve this important aspect of HIV care.

Counseling does not occur
Counseling occurs Total
Patient reports safe sex
14 missed opportunities to reinforce patient's safe sex practice
11 encounters with reinforcement of patient's safe sex practice
25
56
Total 57 24 81
Patient gives indication of unsafe sex
43 missed opportunities to address behavior change toward safer sex
13 encounters addressing behavior change toward safer sex

PUBLIC OPINIONS ABOUT PAYING PEOPLE TO QUIT SMOKING James D. Park 1; David A Asch1.
1University of Pennsylvania, Philadelphia, Pennsylvania. (Tracking ID # 11142)

BACKGROUND: Paying people to quit smoking has been shown to be at least as effective as more traditional pharmacologic approaches (Volpp and Das, 2009). Randomized trials comparing the use of financial incentives to conventional care have demonstrated abstinence rates of 20.9% vs. 11.8% for usual care at 6 months (Volpp et al, 2009). Despite their effectiveness, financial incentives remain controversial. Social and ethical concerns include the appearance of rewarding individuals for unhealthy lifestyle choices, a sense of undermining personal responsibility, and the acceptability of money as a treatment. To understand the extent of these concerns, a randomized controlled public opinion survey was performed. METHODS: Study population: In order to reflect broad public representation, individuals 18 years or older waiting at major transportation depots in Philadelphia were approached between June and August 2010. Participants were compensated with a candy bar for completing the questionnaire.

Questionnaire design: One of three versions was randomly distributed to participants. All participants were asked whether they would support a $25 increase in their annual health insurance premium to pay for a smoking cessation treatment. In version 1, the question was prefaced by According to research, a new treatment helps some people to quit smoking. New treatment was changed to new medication in version 2 and paying people in version 3.

In addition to smoking status, political affiliation, and sociodemographic information, participants were asked to assign responsibility for smoking cessation among individuals, other people/society, and chance/luck using 9 statements adapted from the Multidimensional Health Locus of Control Questionnaire (Wallston et al, 1994). Using a 6-point Likert scale, 3 items for each domain were used.

Analysis: Chi-square tests were used to compare rates of support. Multivariate logistic regression was used to identify predictors of willingness to support a smoking cessation policy on the entire sample

and on those responding separately to each of the three versions. Hypotheses were generated prior to data collection. Statistical testing was two-sided and significant for p-values <0.05.
RESULTS: 1,010 individuals completed the question about willingness to support the policy. 52.8% were female, 26.9% African-American, 17.5% current smokers, and 46.3% had a household income <$40,000. Overall support for increasing health insurance premiums by $25 to pay for any smoking cessation treatment was 41.6%. The financial incentive survey received the lowest support rate (39.3%) but did not statistically differ from the treatment (45.8%, p=0.14) or medication (41.7%, p=0.58) versions.
In subgroup analyses, current smokers overall support for a smoking cessation policy (54.9%) was significantly higher than previous smokers(41.5%, p=0.005) or lifetime non-smokers (36.9%, p<0.001). Within each smoking category, participants showed similar support for each of the three versions. Within the lower income group (household income <$40,000), the financial incentive version (34.8%) was statistically lower than the medication version (49.4%, p=0.04) but not the generic treatment (47.2%, p=0.06).
Participants with Democrat affiliation had a higher overall support rate(45.7%) than Republicans (30.3%, p=0.001). When considering the financial incentive, Republicans (23.3%) had a significantly lower support rate than Democrats (40.6%, p=0.04).
Multivariate logistic regression revealed that current smoking status (OR2.95; 95% CI: 1.90-4.60), age in ten year increments (OR 1.22; 95% CI: 1.08-1.38), Democratic affiliation (OR 1.11; 95% CI: 1.00-1.23), and endorsement of an external locus of control for smoking cessation (OR 1.10; 95% CI: 1.05-1.16) were associated with willingness to support any smoking cessation policy. When considering the financial incentive policy, endorsement of an internal locus of control for smoking cessation (OR 0.87; 95% CI: 0.78-0.96) was a negative predictor of the willingness to support the policy. CONCLUSION: Only 41.6% of the participants supported any investment in smoking cessation treatment, although that support varied by sociodemographic characteristics, political affiliation, and expressed views on the locus of responsibility for smoking cessation. The financial incentive policy received the lowest rate of support, but that support did not differ significantly compared to medication or generic treatment policies. This research suggests that a financial incentive would be perceived no differently than currently used medications for smoking cessation. Rather, much of the negative perceptions involving financial incentives and tobacco cessation may be targeted to the broader issue of whether to help people with a socially stigmatized health behavior.
IS AN OBESITY COUNSELING CURRICULUM FOR RESIDENT PHYSICIANS ASSOCIATED WITH PATIENT WEIGHT LOSS IN PRIMARY CARE? Melanie Jay 1; Colleen Gillespie 1; Sheira Schlair 2; Stella Savarimuthu 1; Daniel Erck 3; Scott Sherman 4; Sondra Zabar 1; Adina Kalet1. 1New York University School of Medicine, New York, New York ;
2Montefiore Medical Center, New York, New York ; 3West Virginia School of Osteopathic Medicine, Lewisberg, West Virginia ; 4New York Harbor VA, New York, New York . (Tracking ID # 11143)
BACKGROUND: There is little evidence that physician training in evidence-based obesity counseling techniques affect patient outcomes. Intensive counseling has been proven to reduce weight while evidence on brief, focused physician- delivered counseling, like the 5As model (assess, advise, agree, assist, arrange), has been inconclusive. We use patient exit interviews and chart reviews to explore whether patients weight status is associated with resident training after a 5As obesity counseling curriculum.
METHODS: Twenty-three primary care residents were scheduled into either an intervention (5-hr 5As obesity counseling curriculum, n=12)
or control group (standard residency training, n=11). Over a 7-month period, we interviewed 158 of the residents obese patients (Body Mass Index >or=30 kg/m2) post medical visit about the nature and quality of obesity counseling that occurred, during that index visit. We then conducted chart reviews to determine weight

at all subsequent medical visits within 6 months and calculated weight change by subtracting the patients weight (kg) measured at the latest time point within the 6 month period from the index visit weight. Quality of obesity counseling was calculated as the percent of 21 possible 5As practices that the patient reported the resident physician used during the index visit. We characterized weight loss/gain by both patient (BMI, gender, race, language, motivation and intention to lose weight, patient activation) and resident variables (quality of obesity counseling, participation in the curriculum) and then used exploratory regression analyses to identify the combined influence of patient and resident characteristics on weight loss/gain. RESULTS: Fifty-six percent (88/158) of patients had visits within a 6 month period subsequent to the index visit, mean number of visits was 4.8 (SD=3.7), 53% of follow-up visits were with the same resident (SD=43) with a mean of 3.8 patients/resident (range 111). Over a 6 month period following the index visit, the mean weight change in all patients was -.32 kg (SD=2.3, range 8.2 - +5.8). Mean weight loss among patients initially seen by a resident who completed the obesity counseling curriculum (.7 kg, SD=2.4, n=43) tended to be greater than mean weight loss for patients initially seen by residents who had not completed the curriculum (+.1 kg, SD=2.2, n=45) (p=.084). Six percent of patients of curriculum residents lost >5% of body weight compared with none of the patients of control residents (p=.092). The exploratory regression model explained 11% of weight change variance (p=.039). Having a resident physician who completed the curriculum accounted for 5% of the variance (p=.037) after controlling for patient BMI, gender, race, and activation stage and quality of 5As counseling. CONCLUSION: Patients of resident physicians who had completed a 5As-based obesity counseling curriculum lost slightly more weight (< 1 kg) than patients of residents who had not completed the curriculum, but the magnitude of weight loss was small and significant only after controlling for patient and resident variables. Further research is needed to better understand how much physician training is needed to more substantially affect patient weight outcomes.

PALLIATIVE AND ONCOLOGIC CO-MANAGEMENT: SYMPTOM MANAGEMENT FOR OUTPATIENTS WITH CANCER Kara Bischoff 1; Vivian Weinberg 1; Michael Rabow1. 1UCSF, San Francisco, California. (Tracking ID # 11144)

BACKGROUND: Although outpatient palliative care clinics are increasingly common, evidence of their clinical efficacy is limited. This prospective study assessed the impact of palliative care co-management on symptoms and quality of life among ambulatory patients at a comprehensive cancer center.

METHODS: 267 adult outpatients with cancer were referred by their oncologist and seen for at least 2 visits within 120 days at the UCSF Symptom Management Service; 152 of these patients were also seen for a third visit within 240 days of the first. Patients completed a modified Edmonton Symptom Assessment Scale and a validated spiritual well-being questionnaire prior to each visit. Overall change in symptom severity from the first to subsequent visits was calculated using two-tailed analysis of variance (ANOVA) methods for repeated measures; a test for a trend in scores over time was defined by a linear contrast. ANOVA models and Kruskal-Wallis tests were used to determine the difference in means and distributions, respectively, for baseline symptoms and for pairwise change in symptoms according to demographic and clinical variables.

RESULTS: At baseline, mean age of studied patients was 57.3 years (SD13.9). Median time since cancer diagnosis was 17.5 months (range 18 256). Fifty-four percent of patients were female; 67% were Caucasian. Prostate, breast, gastrointestinal, and gynecologic cancers were the most common diagnoses. Fifty-nine percent of patients had metastatic disease at baseline. During the study period, 68% of patients received oncologic treatment (chemotherapy, hormonal therapy or radiation) and only 3% were enrolled in hospice. At baseline, severity of evaluated symptoms did not differ significantly by presence of metastatic versus localized disease. However, female gender, African-American ethnicity, and non-prostate cancer diagnoses were associated with greater baseline pain ($p=0.02$, $p<0.001$, $p<0.001$, respectively) and fatigue ($p=0.05$, $p=0.02$, $p<0.001$, respectively).

Second clinic visits were on average 41 days after the first. Between the first and second clinic visits there was

a significant improvement in pain (p<0.001), fatigue (p<0.001), anxiety (p<0.001), depression (p<0.001), quality of life (p=0.002) and spiritual wellbeing (p<0.001), but not nausea (p=0.14) or relationship problems (p=0.31). For the subset of patients with evaluable data who were seen for a third visit, the improvement in pain, fatigue, anxiety, depression, quality of life and spiritual wellbeing observed at the second visit persisted to the third visit (p<0.005 for each symptom).
CONCLUSION: Palliative care, provided in a symptom management clinic concurrent with oncologic care, was associated with significant improvement in nearly all symptoms evaluated. A sustained effect is suggested by the subset of patients seen for a third visit. Although cancer stage has a key impact on prognosis, cancer patients with localized disease had a symptom burden similar to patients with metastatic cancer. To control for the impact of time and non-palliative treatments, as well as for referral bias, randomized controlled studies of outpatient palliative care are indicated.
COMORBID DIABETES AND EXPENDITURES AMONG MEDICARE BENEFICIARIES WITH HEART FAILURE Saul Blecker 1; Frederick Brancati1. 1Johns Hopkins University School of Medicine, Baltimore, Maryland. (Tracking ID # 11146)
BACKGROUND: Diabetes is common in heart failure patients and has been associated with an increased mortality rate. We examined whether diabetes was associated with increased expenditures, procedures, and hospitalizations among a nationally representative sample of Medicare beneficiaries with heart failure near the end of life.
METHODS: We performed a cross-sectional analysis of resource utilization among Medicare beneficiaries with heart failure during the last six months of life. Data were obtained from a 5% sample of beneficiaries with Medicare Parts A and B. We included all beneficiaries over the age of 65 who had a diagnosis of heart failure and died in 2007. Our primary exposure was presence of diabetes. Diagnoses of heart failure and diabetes were established using the International Classification of Diseases, Ninth Revision (ICD-9) codes 428 and 250, respectively, listed as either a hospital discharge diagnosis or in at least two physician claims in the year preceding the last six months of life. The primary outcome was total Medicare expenditures during the last six months of life. Secondary outcomes were other markers of utilization, including number of hospitalizations, number of intensive care unit (ICU) days, and performance of procedures, including cardiac catheterization, implantable cardiac defibrillator (ICD), and cardiac resynchronization therapy (CRT). Characteristics between individuals with and without diabetes were compared using chi-squared tests for categorical variables and Wilcoxon rank sum tests for continuous variables. We used negative binomial and log-linear regression models to compare utilization between beneficiaries with and without diabetes
with adjustment for covariates, including age, gender, race, geographic location, comorbidities, and prior hospitalizations.
RESULTS: The prevalence of diabetes was 41.7% (n=6,922) among 16,613 Medicare beneficiaries with heart failure who died in 2007. Individuals with comorbid diabetes were younger (81.8 vs 85.8, p<0.001), more likely to be male (45.9% vs 40.2%, P<0.001), had higher numbers of hospitalizations in the prior year (mean 2.6 vs 1.8, p=0.02), and had higher rates of hypertension, cardiovascular disease, and kidney disease as compared to individuals without diabetes. Diabetes was associated with higher total expenditures (mean $39,042 vs $29,003, p<0.001), even after adjusting for covariates (adjusted cost ratio 1.08, 95% CI1.05-1.12). For both diabetics and non-diabetics, over half of Medicare expenditures were related to hospitalization costs (mean $22,516 vs $15,721, p<0.001). When compared to their counterparts without diabetes, beneficiaries with diabetes had higher rates of hospitalization (adjusted incidence rate ratio (aIRR) 1.09, 95% CI1.05-1.12) and days spent in the ICU (aIRR 1.19, 95% CI 1.09-1.29). However, after adjustment, diabetes was not associated with a significant increase in performance of cardiovascular procedures, including cardiac catheterization (adjusted prevalence ratio (aPR)1.03, 95% CI 0.87-1.21), ICD (aPR 1.03, 95% CI 0.75-1.41), and CRT (aPR 0.94, 95% CI 0.59-1.49).

CONCLUSION: In our nationally representative sample of Medicare beneficiaries with heart failure near the end of life, comorbid diabetes was extremely common. Comorbid diabetes was associated with significantly higher Medicare expenditures, much of which appeared to be driven by increased rates of acute and intensive care hospitalizations. Rates of invasive cardiovascular procedures were, however, similar in individuals with and without diabetes. To reduce the substantial costs associated with diabetes among heart failure patients, clinicians and policy makers should focus on programs designed to prevent hospitalizations in this high-risk population.

SCREENING FOR PERIPHERAL ARTERIAL DISEASE IN ASYMPTOMATIC INDIVIDUALS: A SYSTEMATIC REVIEW AND META-ANALYSIS Amy Tu Wang 1; Mohammad Hassan Murad 2; Rafael Malgor 3; Adnan Rizvi 4; Tarig Elraiyah 2; Melanie Lane 2; Larry Prokop 2; Victor Montori2. 1Mayo Clinic, Rochester, Rochester, Minnesota ; 2Mayo Clinic, Rochester, Minnesota ;
3Stony Brook UniversityMedicalCenter, StonyBrook,NewYork; 4Minneapolis Heart Institute Foundation at Abbott Northwestern Hospital, Minneapolis, Minnesota . (Tracking ID # 11148)

BACKGROUND: Peripheral arterial disease (PAD) is estimated to affect 8 million Americans and is associated with increased risk of morbidity and mortality. PAD can be reliably detected via a widely available, noninvasive, and inexpensive tool, the Ankle Brachial Index (ABI). Although only 10% of individuals with PAD present with classic symptoms, the United States Preventive Services Task Force issued 2003 recommendations against screening for PAD in asymptomatic individuals, while other groups including the American Heart Association recommend for ABI screening in asymptomatic individuals. Given these disparate recommendations, we performed an updated systematic review to include new evidence in hopes of shedding light on this controversial issue.

METHODS: We conducted a systematic review and random-effects meta-analysis of electronic bibliographic databases for studies that evaluated the outcomes of using ABI to screen asymptomatic individuals for PAD.

RESULTS: Thirty-one studies reported the yield of screening asymptomatic individuals for PAD to average 16% (range 1-42%). Yield of screening increased with age and risk factors for cardiovascular disease. PAD was fairly uncommon in younger and lower risk populations.

Nineteen studies reported on the association between PAD and all-cause mortality and cardiovascular mortality. Compared to patients without PAD, patients with PAD were at higher risk of all-cause mortality (pooled hazard ratio 2.99; 95% confidence interval (CI), 2.16-4.12) and of cardiovascular mortality (2.35; 95% CI, 1.91-2.89). Five studies reported outcomes of interventions provided to asymptomatic PAD patients identified via screening. These studies used different outcomes making it difficult to draw meaningful conclusions. No studies compared effects of utilizing screening ABI versus no screening in asymptomatic individuals in terms of patient important outcomes. CONCLUSION: The current available evidence demonstrates that the yield for screening ABI to identify PAD in asymptomatic individuals is fairly high especially among older patients and those with cardiovascular risk factors. Our review also showed that PAD is associated with a 2 to 3 fold increase in mortality. Unfortunately, there were no studies that directly compared outcomes in groups receiving screening versus those that did not. Thus, we could not recommend for routine screening for PAD in asymptomatic individuals. This further underscores the need for a thoughtfully designed study that answers this patient-important question.

USABILITY TESTING FOR THE DEVELOPMENT OF AN ELECTRONIC HEALTH RECORD INTEGRATED CLINICAL PREDICTION RULES IN PRIMARY CARE Devin Mann 1; Andre Kushniruk 2; Thomas McGinn 3; Alice Li 3; Daniel Edonyabo 3; Lucas Romero 3; Jacqueline Arciniega 3; Dillon Chrimes 2; Joseph Kannry3. 1Boston University School of Medicine, Boston, Massachusetts ; 2University of Victoria, Victoria, British

Columbia ; 3Mount Sinai School of Medicine, New York, New York . (Tracking ID # 11151)
BACKGROUND: Usability testing assesses both the ease of use and ability of clinicians to successfully interact with a prototype patient-oriented computer tool. Usability testing is a critical but underutilized step in the development of health information technology tools. The rapid growth of electronic health records (EHR) in primary care has only increased the need for usability in primary care interventions. In theory, clinical decision support (CDS) systems help EHR users deliver more efficient and effective care. The integration of evidence based medicine (EBM) into EHR systems using CDS tools at the point of care is a critical step towards using HERs to facilitate EBM in primary care. Clinical prediction rules (CPR) such as the Walsh and Heckerling criteria for Strep and Pneumonia, respectively, formally incorporate EBM diagnostic probabilities and provide primary care providers well-validated resources for care delivery. As part of a planned randomized controlled trial testing a new EHR embedded CPR tool (termed iCPR) for strep throat and pneumonia, we conducted usability testing to help develop and refine the new tool.
METHODS: We conducted usability testing to evaluate the main functionalities of the iCPR tool: alerting, risk calculator, bundled ordering, progress note and patient instructions. Eight primary care providers interacted with the prototype iCPR tool using two written clinical scenarios (1 for strep and 1 for pneumonia). Using the think aloud protocol analysis method, providers were encouraged to verbalize their thoughts as they interacted with each component of the tool. Screen capture software and audiotaping were used to record all human-computer interactions. Audio transcripts of subjects verbalizations were annotated with relevant screen movements (e.g. menu selections, etc.) to provide a holistic recording of the provider-iCPR interaction. This data was then coded using thematic protocol analysis by two trained coders with disagreements resolved by consensus. RESULTS: A total of 263 coded observations were recorded that dealt with the following 7 themes (# of unique codes): usability (33),
navigation (26), content (25), usefulness (13), understandability (9), visibility (9), and workflow (27). Code frequency was evenly distributed across providers with the following breakdown across iCPR functionalities: 53 alert, 16 risk calculator, 22 progress note, 14 patient instructions, 93 bundled order set, and 65 global coded segments. Common issues included perceived excessive clicks and readability of text as noted by one user, Its becoming a lot of clicking and reading and you want to do this thing quickly, especially if you have a lot of patients waiting. Providers had generally positive perceptions on how the tool would affect their workflow, along with suggestions for optimizing its implementation. This usability feedback led to critical changes throughout the prototype tool including redesigning the alert mechanism, adjusting the contents of the bundled order sets, revising the progress note templates and reorganizing the patient instructions. CONCLUSION: Usability testing provides critical feedback from users regarding potential barriers towards implementation of a new EHR embedded CDS tool. This data has been used to refine the development of the iCPR tool and will help achieve enhanced workflow integration and acceptance by providers.
ASSOCIATIONS BETWEEN HEALTH LITERACY, CALORIE KNOWLEDGE AND NUMERACY AND FAST-FOOD MENU SELECTION Jing-Yu Pan 1;
Arnoldys Stengel 1; Nichola Davis2. 1Montefiore Medical Center, Bronx, New York; 2Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 11155)
BACKGROUND: Calorie labeling laws require fast-food chain restaurants to post calorie information on menu boards. Initial evaluations of the impact of this law suggest that it may only affect calories purchased in a minority of consumers. The Patient Protection and Affordable Care Act mandates that calorie labeling be implemented nationwide and in addition to posting calorie information, caloric recommendations must also be posted. We sought to examine whether health literacy, calorie knowledge, or numeracy may affect calories purchased among a primary care adult population.
METHODS: We surveyed 131 adult patients attending a public hospital clinic in the Bronx, NY. Consecutive patients were recruited from the clinic waiting room to complete a 65-item questionnaire administered by

interview. The questionnaire included frequency of fast food restaurant use, calorie knowledge, weight loss attempts within the past year, health literacy and subjective numeracy. Participants were asked to select food choices from 2 fast-food menus, the first menu had no calorie information, and the second menu had the calorie information. Body mass index was determined from chart documentation of height and weight. Calorie knowledge was determined by asking participants if they knew on average how many calories most Americans should eat each day. Health Literacy was assessed with the 6-item Newest Vital Sign, which asks 6 questions about a nutrition food label (response range 06). Numeracy was assessed with Fagerlins Subjective Numeracy Scale which asks 8 questions about preference for numerical data and perceived ability to work with numbers (response range 06). The sum of the calorie items selected from the menus with and without the calorie information was calculated. Unpaired t-tests examined whether mean scores of calories selected differed among those with higher vs. limited health literacy, those who knew calorie recommendations compared to those who did not, and those with high vs. low numeracy.
RESULTS: In this population, mean (+/SD) age was 43+/16, mean (+/SD) BMI was 31+/8, and 63% reported trying to lose weight in the past 1 year. Thirty-seven percent reported going to a fast-food restaurant one or more times in a week, with some respondents going as often as 10 times a week. Forty percent of survey respondents correctly chose 2000 calories as the average number of calories most

adult Americans should consume daily. Mean (+/SD) response on the health literacy scale was 2.6+/1.9,with 35% of respondents having a score of less than 2 suggesting limited health literacy. Participants selected an average of 763+/448 calories on a fast-food menu without calorie information, compared to 511+/336 calories ($p<0.005$) when calories were added. Of 131 participants, 48 completed all survey measures. Among these participants, the sum of calories selected by those with limited health literacy was (1198+/1094); significantly higher than the calories selected by participants with higher health literacy (762+/435), $p=0.04$. Adults who knew the caloric recommendations chose 854+/716 calories and those who did not know the calorie recommendations chose 801+/438 calories, $p=0.76$. Participants below the median level of numeracy selected 876+/547 calories and those above the median selected 827+/700 calories, $p=0.79$. CONCLUSION: Our findings suggest that health literacy may be an important factor in calories selected at a fast-food restaurant. While participants with higher knowledge and higher numeracy selected fewer calories, this was not statistically significant in our sample. As calorie labeling is implemented nationally it will be important to examine knowledge, health literacy and numeracy as potential barriers in using calorie information.
GENDER CONCORDANCE OF PATIENTS AND PROVIDERS: BALANCING PATIENT PREFERENCE WITH EDUCATIONAL NEEDS Amy Devlin 1; Long Ngo 1; Carol K. Bates 1; Diane Brockmeyer1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 11159)
BACKGROUND: Prior studies show patients prefer same-sex physicians; we believe this drives gender imbalance in our resident outpatient panels. Among our senior residents, males have 65% male patients, and females have 80% female patients. This limits resident experience managing gender specific issues.
Our clinic graduates 44 residents annually, transferring 3500 patients to new interns. We preferentially transitioned patients to opposite gender interns over the past 2 years. Patient assignments were made to interns of the opposite gender of the patient 67% of the time. 86% of patients were assigned to an intern who was the opposite gender of their prior resident PCP. Exceptions were made to assign equal numbers of patients to new interns, to match language for non-English speaking patients, and for preceptor continuity for sicker patients. Patients were notified of their new PCP via letter.
This study examines the impact of change in physician gender on the likelihood of patient follow-up.
METHODS: In this retrospective cohort study, patient follow-up visits were recorded for the 12 months after assignment to new PCP for the June 2008 and 2009 graduation cohorts. The primary exposure was assignment of a new, opposite-sex primary care physician (female-to-male PCP or male-to-female PCP) vs. unexposed

groups (male-to-male PCP, female-to-female PCP). 6150 patients were switched to opposite gender PCPs and 987 patients remained in the unexposed group (N=7137). The binary outcome variable was follow-up vs. no follow-up with assigned PCP, or with any MD or NP in the practice. Logistic regression was used to estimate unadjusted and adjusted odds ratios of the effect of switching patients to opposite gender PCPs on the probability of follow-up with PCP and with any provider. Two linear contrasts from the logistic regression models were used to obtain odds ratios for the comparison between female-to-male versus female-to-female PCP, and male-to-female versus male-to-male PCP switch. To address confounders, covariate adjustments were made for age, gender, diabetes, chronic narcotic use, known significant illness, and language (English vs. non-English speaking).
RESULTS: At 12 months after assignment to new PCP, 48% of patients had follow up in the practice, and 16% of patients followed up with the assigned new PCP. If the new PCP was the same gender as prior PCP, rates were 55% and 23%. If the new PCP was different gender from prior PCP, rates were 47% and 11%. Patients with existing illness, diabetes, pain treated with narcotics and non-English speaking patients had greater follow-up rates.
Multivariable models were used to adjust for potential confounders of age, gender, illness, diabetes, narcotic use, and non-English speaking patients. For rates of follow up with assigned PCP, adjusted odds ratios showed patients transitioned from female-to-male vs. those continuing with female PCPs were 52% less likely to follow-up with the assigned PCP (OR=0.48, CI=0.38-0.60). Patients transferred from male-to-female PCPs were 26% less likely to follow-up than male-to-male PCPs (OR=0.74, CI=0.56-0.98).
CONCLUSION: Reassigning patient panels to opposite gender PCPs appeared to decrease patient follow-up. Further investigations are needed to optimize continuity of care for patients while providing a balanced resident educational experience.
ADHERENCE TO CHRONIC DISEASE MEDICATIONS AMONG NEW YORK CITY MEDICAID ENROLLEES
Kelly A Kyanko 1; Robert Franklin 2; Sonia Angell3. 1Yale School of Medicine, New Haven, Connecticut; 2New York State Department of Health, Albany, New York; 3New York City Department of Health and Mental Hygiene, New York, New York. (Tracking ID # 11162)
BACKGROUND: Adherence to medications for hypertension, diabetes, and dyslipidemia is a critical component of primary and secondary cardiovascular disease prevention and control. While provider and payor organizations such as Medicare/Medicaid have traditionally been involved in introducing medication adherence initiatives, local public health departments can play a unique role in monitoring, piloting and promoting best practices, and in facilitating systems-level changes designed to increase adherence rates. To better understand factors related to adherence in the New York City (NYC) Medicaid population on chronic disease medications, and to establish a method for evaluating potential interventions, the NYC Department of Health and Mental Hygiene, in collaboration with the New York State Department of Health, aimed to 1) determine the rate of medication adherence among NYC Medicaid enrollees with chronic disease (diabetes, hypertension, or dyslipidemia) on maintenance medications, 2) identify predictors of medication adherence, and 3) describe prescribing patterns (number of days supplied).
METHODS: We performed a retrospective analysis of pharmacy claims data from the New York State Medicaid system. Included were individuals ages 2064 continuously enrolled in Medicaid and who had at least two fills of an eligible medication for dyslipidemia, diabetes, or hypertension during the observation period from July 1, 2008-June 30, 2009, and at least one fill in the three months prior. Adherence was measured using the medication possession ratio, with adequate adherence defined as 80%. Multivariable logistic regression was used to predict medication adherence as a function of race/ethnicity, age, gender, number of medications, and number of conditions. RESULTS: Data were analyzed for a total sample of 160,238 patients, involving over 3.5 million prescription fills. Overall, 63% of enrollees were adherent to their chronic disease medication regimens. In multivariable logistic regression older age and taking a larger number of medications were significantly

associated with increased adherence. Compared with whites, Asians were more likely to be adherent (OR=1.28, 95% CI: 1.24-1.33), whereas blacks were less likely to be adherent (OR=0.84, 95% CI: 0.81-0.86). The majority of prescriptions filled were for 30 days supply, rather than 60 or 90 days (95.9%, 0.6% and 2.5%, respectively).

CONCLUSION: In a population of NYC Medicaid recipients on stable medication regimens for hypertension, diabetes, and/or dyslipidemia, adherence to medications for these conditions was inadequate and racial disparities were indentified. Results from this study may be used by health departments and other providers to inform development and evaluation of future medication adherence programs. Because prior studies have shown improved adherence with use of prescriptions greater than 30 days supply, the low prevalence of these larger prescriptions in our analysis identifies a potential target for local systems-level interventions designed to improve medication adherence and address health disparities.

KNOWLEDGE LEVEL ABOUT HPV AMONG AN UNDERSERVED LATINA POPULATION IN METRO-ATLANTA: NEW OPPORTUNITIES FOR TARGETED INTERVENTIONS

Anna Acosta 1; Loida Bonney 2; Michael Fost 2; Victoria L Green 3; Carlos del Rio4. 1Emory Internal Medicine Residency, Atlanta, Georgia ; 2Emory School of Medicine, Department of Medicine, Atlanta, Georgia ; 3Emory School of Medicine, Department of Obstetrics and Gynecology, Atlanta, Georgia ; 4Emory School of Public of Health, Atlanta, Georgia . (Tracking ID # 11163)

BACKGROUND: Human papillomavirus (HPV) is the leading cause of cervical cancer. Currently there is a two-pronged approach employed to prevent development of cervical cancer: 1) secondary prevention via Papanicolaou smear screening, used in the U.S. since the 1950 s, and 2) primary prevention with use of the recently introduced HPV vaccine. Despite the availability of effective secondary prevention, Latina women are disproportionately affected by cervical cancer incidence and mortality, with death rates more than 50% higher than in non-Hispanic white women. Explanations for these findings include lack of access to healthcare, lack of knowledge and health literacy, poor follow-up, immigration status, and cultural beliefs, among others. Improving HPV vaccination coverage is critical in order to decrease this health disparity.

Recent data from our group suggests that lack of knowledge about cervical cancer and its cause may play a crucial role in shaping cervical cancer prevention health service use, and thus, incidence of disease among Latina women. Because the Southeastern U.S., and especially the metro Atlanta area, is beginning to support increasing numbers of Latino immigrants, it is important to address the specific knowledge gaps that impact this population.

The objective of this study is to evaluate the level of knowledge of HPV in a sample of Latinas living in metro Atlanta, and to assess the factors correlated with differing levels of knowledge.

METHODS: This study is a secondary analysis of data from a cross-sectional survey of a convenience sample of Latina women recruited from the waiting room of two clinics serving an indigent population. Women completed the Survey using Computer Assisted Personal Interview (CAPI) with Audio Computer Assisted Self Interview (ACASI) components. Knowledge level of HPV was measured by the number of correct responses to five questions. Thus each survey respondent received a score between 0 and 5. The score was then tested for correlation with demographic factors and other characteristics of the survey respondents by Fishers exact test (SAS, version9.2; SAS Institute, Cary, NC). P-values <0.05 were considered significant.

RESULTS: A total of 86 Latina women responded to the knowledge items, which included five questions regarding HPV knowledge. Eighty percent of these women were of Mexican origin. Among the study participants, 54% correctly identified HPV as the most common sexually transmitted infection (STI), 54% responded incorrectly that herpes was the most common STI, 74% correctly responded that HPV causes

cancer, 29% correctly answered that
HPV can cause penile cancer, and 12% responded correctly that HPV may not have symptoms.
Multivariate analysis revealed that those who already had received the vaccine scored higher on the knowledge questions (p=0.0054). Additionally, there were higher scores in those who feel they speak English best, as opposed to Spanish (p=0.061), those who read or speak primarily in English (p=0.0309), those who primarily think in English (p=0.0433), and those who speak in English with friends (p=0.0474). Although not significant, there was a trend that first generation Latinas scored lower on the knowledge questions (p=0.16).
Further examination found that those who speak or read primarily in English (p=0.0049), those who think in English (p=0.0384), those who feel they speak English best (p=0.0079), and those that speak in English with friends (p=0.0312) were more likely to have received the vaccine. First generation Latinas were also less likely to have received the vaccine (p=0.0306).
CONCLUSION: Among a convenience sample of underserved Latinas recruited from outpatient clinics, most were aware that HPV is associated with cervical cancer. However, the highest level of knowledge appears to be associated with those who are more comfortable with the English language. Additionally, this subset of the population is largely the same persons who have already been vaccinated. Therefore, further strategic educational interventions in this population should target first-generation women or those less comfortable with the English language. The most critical intervention to decreasing the incidence of cervical cancer may be improving access to education and increasing English proficiency.
COLORECTAL CANCER SCREENING IN PRIMARY CARE Craig Daniel Seaman 1; Bruce Ling 2; Maria Mor2. 1University of Pittsburgh Medical Center, Glenshaw, Pennsylvania ; 2Veterans Affairs Medical Center, Pittsburgh, Pennsylvania . (Tracking ID # 11164)
BACKGROUND: Colorectal cancer is the 3rd most common cancer and 2nd leading cause of death due to cancer. The United States Preventive Services Task Force (USPSTF) recommends annual fecal occult blood test (FOBT), flexible sigmoidoscopy in combination with FOBT, or colonoscopy as colorectal cancer screening (CRC) methods. CRC screening is significantly underutilized with CRC screening rates estimated between 55-63%. Effective patient-provider communication is necessary in all aspects of medical care. Our study assessed whether or not increased level of discussion regarding CRC screening between patient and provider is associated with increased CRC screening rates.
METHODS: The study consisted of males 5074 years of age due for CRC screening during the 12 month period following enrollment. Transcribed audiotaped visits between patient and provider, an attending physician, at a single Veterans Affairs Medical Center in Pittsburgh, PA, were categorized as CRC screening absent, CRC screening mentioned, or CRC screening discussion present. Outcomes were determined by reviewing electronic medical records 15 months after enrollment in the study with outcomes defined as completion of FOBT, flexible sigmoidoscopy, or colonoscopy. Two sided p values were calculated with Fishers exact methods.

RESULTS: The analytic cohort consisted of 66 patients due for CRC screening that had transcribed audiotaped visits. 22 (33%) patients completed CRC screening with 8 (36%) categorized as CRC screening absent, 11 (50%) categorized as CRC screening mentioned, and 3 (14%) categorized as CRC screening discussion present. 44 (67%) patients did not complete CRC screening with 22 (50%) categorized as CRC screening absent, 12 (27%) categorized as CRC screening

mentioned, 9 (20%) categorized as CRC screening discussion present, and 1 (3%) whose transcript was missing (p value=0.30). 42.1% of patients that agreed to CRC screening during the encounter with the provider did not complete CRC screening. These patients were compared with patients that reported intent to complete CRC screening and did so. Multiple variables were analyzed with a statistically significant difference present between the aforementioned groups with respect to prior history of CRC screening (p value=<0.001). Among

patients that voiced intent to complete CRC screening and did so, 12 (75%) previously completed screening compared with 4 (25%) that never completed screening. Among patients that voiced intent to complete CRC screening but failed to do so, 2 (12%) previously completed screening compared with 14 (88%) that never completed screening.
CONCLUSION: The level of discussion between patient and provider does not predict completion of CRC screening. In addition, very limited discussion occurs between patient and provider regarding CRC screening. Among patients that voiced intent to complete CRC screening, a prior history of CRC screening predicts subsequent completion of screening. Furthermore, I hypothesize that increased level of discussion between provider and patient regarding CRC screening is negatively associated with completion of CRC screening because patient reluctance results in increased level of discussion (as opposed to increased level of discussion resulting in patient reluctance). Also, focusing additional efforts on individuals agreeing to CRC screening that have never completed screening may increase screening completion rates.
MISSED OPPORTUNITIES FOR ADVANCE CARE PLANNING IN PRIMARY CARE Sangeeta Ahluwalia 1; Jennifer Levin 1; Karl Lorenz 1; Howard Gordon2. 1Veterans Administration, Los Angeles, California ; 2University of Illinois, Chicago, Chicago, Illinois . (Tracking ID # 11167)
BACKGROUND: Advance care planning (ACP), a process of patient-provider communication by which a patient can make their preferences for future care known, is particularly relevant for patients with heart failure (HF) , who face a highly variable trajectory characterized by periods of medical crisis, and where considerable uncertainty exists about the timing and nature of death. There is indirect evidence to suggest that ACP discussions are limited in the primary care setting; such discussions are often avoided until death is imminent. A key barrier to engaging in ACP reported by primary care clinicians is the lack of opportunity during a busy clinic visit to raise this complex topic with their patients. The purpose of this study was to 1) determine the frequency and type of ACP communication between HF patients and their primary care providers (PCP) during clinic visits following discharge from a HF hospitalization and 2) to characterize missed opportunities for engaging in ACP during the visit.
METHODS: We conducted a content analysis of 76 post-discharge primary care clinic visits, that were recorded and transcribed, with veterans 65 years with HF and their PCP/Transcripts were analyzed for the presence of 5 components of ACP as defined by existing literature: explanation of disease trajectory, prognosis communication, discussion or completion of formal directives, discussion or identification of a surrogate decision-maker, and personal and psychosocial planning for the future. Transcripts were also analyzed using grounded theory methods for missed opportunities for providers to engage in ACP, defined as direct communication by the patient providing information regarding their thoughts, concerns, or questions related to any of the 5 components of ACP that was not fully encouraged or adequately responded to by their provider.
RESULTS: Out of the 76 unique clinic visits analyzed, only one contained a discussion of all 5 components of ACP. Of the remaining 75 visits, 15% (n=11) included an explanation of disease trajectory, 23% (n=17) included prognosis communication, 4% (n=3) included a discussion of formal directives, 0% (n=0) included discussion of a surrogate decision-maker, and 4% (n=3) included personal and/or psychosocial planning for the future. The following categories of missed opportunities for engaging in ACP emerged from the analysis: i) emotional opportunities, where veterans expressed concern or worry regarding their prognosis, future functional abilities and likelihood of decline, or their overall expected health state, ii) information-seeking opportunities, where veterans sought information on their prognosis, specific treatment options, or future care, and iii) social-support opportunities, where veterans discussed their future health within the context of their family/caregiver or broader social environment. Categories of provider responses to these communications included: i) incomplete responses, where the physician did not fully explore the comment, ii) misdirected responses, where the provider bypassed the comment by engaging in a related discussion and iii) terminated responses, where the provider invalidated or ignored the veterans thoughts or feelings.

CONCLUSION: These findings demonstrate particularly limited engagement in ACP by PCPs with their patients with HF. Patients actively seek information, empathy and guidance from their providers regarding their illness that may be overlooked or inadequately addressed by their provider. The missed opportunities for ACP identified here represent meaningful entrees into discussions about planning and preparing for future care; active recognition of these opportunities may help providers to initiate what is already a difficult and complex topic.

SOCIAL DISPARITIES IN MAIL-ORDER PHARMACY USE: AN EXAMPLE OF THE INVERSE CARE HYPOTHESIS Andrew J Karter 1; Julie A Schmittdiel 1; Melissa M Parker 1; Dean Schillinger 2; Howard H Moffet 1; Wendy T Dyer 1; James Chan 1; William H Herman 3; O. Kenrik Duru4.

1Kaiser Permanente, Oakland, California ; 2University of California, San Francisco, San Francisco, California ; 3University of Michigan Medical Center, Ann Arbor, Michigan ; 4University of California, Los Angeles, Los Angeles, California . (Tracking ID # 11174)

BACKGROUND: A third of all chronic disease prescriptions in the US are filled by mail. Use of Mail-Order Pharmacy (MOP) has been associated with improved adherence, better LDL-C control, and cost savings for health plan operations when compared to community (walk-in) pharmacies. Tudor-Harts inverse care hypothesis posits lagging uptake of innovations by vulnerable populations due to resource and access barriers (resulting in more care for those who need less, and less care for those who need more). While we have reported ethnic disparities, there has not been formal evaluation of disparities in mail-order pharmacy across other social indicators, or studies of how incentives to increase use of MOP may affect existing disparities in MOP utilization.

METHODS: We evaluated social disparities in prevalent use of MOP (defined by any mail order refills in year prior to baseline survey) in a sample of 17,758 Kaiser Permanente patients with diabetes who responded to a survey (62% response rate) from the Diabetes Study of Northern California (DISTANCE). Each subject had a pharmacy benefit and had filled a cardiometabolic medication (diabetes, anti-hypertensive, or lipid-lowering) in the year prior to baseline. We also evaluated new MOP use (i.e., incident use among subjects without previously recorded MOP use) during the 12 months after a new financial incentive was offered to promote MOP in specific subsets of

pharmacy benefit beneficiaries. We used primarily unadjusted summary statistics (%), but also specified difference-in-difference models using modified Poisson regression models with robust standard errors to estimate relative risk.

RESULTS: There was markedly lower prevalent use of MOP among those with lower income (25% with incomes under $25 K vs. 50% in $80 K+), less education (27% in no degree vs. 43% in college grads), inadequate health literacy (32% vs. 43% in adequate HL), non-English speakers (23% vs. 38% in English speakers) and minority patients (25% in African Am and Latinos, 48% in Asians, 53% in Whites)($p<0.0001$ for all). Adjustment for age, sex, self-reported difficulty navigating the phone refill system, depressive symptoms, and distance from home to pharmacy did not change patterns substantively. Among the subset of previous non-users, 36% became MOP users in the year after being offered a financial incentive compared to 9% among those not offered the incentive. Among non-users offered incentives, uptake was inversely related to income (see figure). Similarly, greater response to incentives was also observed for other social indicators of advantage (e.g., adequate health literacy). CONCLUSION: We observed substantive social disparities in the prevalence of MOP use. Financial incentives to enroll greatly increased new MOP use among previous non-users overall, but paradoxically, poorer patients were less likely to initiate use despite offerings of reduced out-of-pocket costs. While our study did not examine adherence and health outcomes, it does suggest that health plans need to

tailor and promote innovations such as MOP for vulnerable populations, in order to attenuate disparities that may be exacerbated by broadly applied quality improvement initiatives.
Income differences in new (incident) mail order pharmacy (MOP) use in year after introduction of a financial incentive among those not using MOP prior to incentive roll-out
TREATMENT DELAYS AT A FREE URBAN CLINIC: MAKING A CASE FOR POINT OF CARE A1C TESTING
E. Miranda Gillespie 1; Lauren Jonkman2. 1University of Pittsburgh Medical Center, Division of General Internal Medicine, Pittsburgh, Pennsylvania ; 2University of Pittsburgh School of Pharmacy, Department of Pharmacy and Therapeutics, Pittsburgh, Pennsylvania . (Tracking ID # 11186)
BACKGROUND: The management of chronic diseases, including diabetes, can be particularly challenging for free medical clinics. In addition to the struggles of limited medical resources, limited continuity, and complicated social situations, accessing laboratory testing can also be challenging. The Birmingham Free Clinic, a free, primary care, volunteer-driven clinic in Pittsburgh, Pennsylvania, serves a large population of uninsured patients, many of whom have diabetes. The clinic has no on-site phlebotomy services but currently partners with a local hospital (approximately one mile away) for free limited laboratory testing for the patients. Point of care (POC) testing, specifically for hemoglobin A1C (A1C), offers potential advantages in managing chronic diseases in this setting. POC testing allows
clinicians to make immediate treatment decisions at the point of care rather than requiring patients to make separate trips to the lab. We believe that POC A1C testing can offer particular advantages for a patient population that is low income, has difficulty accessing transportation, and may have transient housing situations. However, with a very limited budget, the clinic has to develop cost effective protocols and interventions. In order to assess the potential advantages of implementing POC testing in a free clinic we first investigated the treatment delays that were associated with the current lab-based, off-site A1C testing.
METHODS: We performed a retrospective chart review of all known patients with diabetes seen at the clinic between June 2010 and October 2010. Data was abstracted from the period of June 2008 through October 2010. Data abstracted included basic demographic information, housing status, monthly income, date(s) that A1C was ordered, date(s) the test was obtained at the lab, and date(s) that patients had clinic follow-and the A1C lab result was acted upon by a clinician. The University of Pittsburgh Institutional Review Board approved this project.
RESULTS: A total of 56 patients were included in the chart review. The majority of the patients were African American (50.9%) men (75%). The mean monthly income was $589.71 (SD 580.04). Mean driving distance from home to clinic was 6.32 miles (SD 5.56). Mean A1C over this time period was 8.88% (SD 2.25). At the time of the analysis, 25% of the patients were homeless, including 5.5% in a drug and alcohol rehabilitation facility attached to the clinic and 20% doubled-up. Over this period, 175 A1Cs were ordered of which 101 (58%) were obtained by patients. It took a mean 65 days (SD 103) for patients to obtain their blood work after receiving a lab requisition. The mean time from date A1C was initially ordered until the A1C results were acted upon was 110 days (SD 124).
CONCLUSION: Our study shows significant delays in care when patients have to go to an offsite lab to obtain tests. In this analysis, we found that it takes more than 2 months for many patients to go to the lab after receiving a laboratory requisition. An additional month often passes before any changes are made to therapy based on those results. POC testing could potentially get patients to goal faster and prevent or delay expensive, life-altering complications. It may also minimize transportation costs and time barriers for patients. Further investigation into the cost effectiveness of POC testing for this population could aid in decisions regarding resource allocation.
COMPARATIVE SAFETY AND EFFECTIVENESS OF DIABETES MEDICATIONS IN SUBPOPULATIONS OF ADULTS WITH TYPE 2 DIABETES
Lauren Block 1; Wendy L Bennett 2; Lisa Wilson 2; Eric B Bass2. 1Johns Hopkins Hospital, Baltimore, Maryland ; 2Johns Hopkins University, Baltimore, Maryland . (Tracking ID # 11190)

BACKGROUND: Although many studies have examined the comparative effectiveness and safety of medications for type 2 diabetes, clinicians need better guidance on how to tailor treatment according to demographic and clinical characteristics of individual patients. METHODS: As part of a comprehensive systematic review, we searched MEDLINE, EMBASE, and Cochrane databases from inception through April 2010 and hand-searched journals and reference lists using search terms for type 2 diabetes and all FDA-approved diabetes medications. Two investigators independently reviewed citations to identify studies that compared the effectiveness and safety of diabetes medications as monotherapy or in combination for sub-populations of patients with type 2 diabetes. We abstracted data from eligible articles and assessed study quality.

RESULTS: We identified 28 studies (21 randomized controlled trials (RCTs) &7 observational studies) that reported outcomes in subgroups of patients. Five studies examined the impact of age on glycemic control, but we were unable to draw conclusions regarding comparative medication effectiveness in older adults with diabetes. Two RCTs conducted subgroup analyses by sex for the outcome of fracture. One 4-year study showed an increased risk of fracture among women treated with rosiglitazone compared with metformin or sulfonylurea (hazard ratio (HR) 1.57 (1.13-2.17; p=0.007) and 1.61, respectively (1.14-2.28; p=0.007). The second 6-year trial confirmed an excess fracture risk in women treated with rosiglitazone plus metformin or sulfonylurea compared with metformin plus sulfonylurea (RR in women 1.82 (1.37-2.41) and in men 1.23 (0.85-1.77)). Two RCTs favored metformin over sulfonylurea among obese patients in terms of weight loss. In one study, obese patients gained on average 3.7 kg (0.5 to 7.9 kg) on sulfonylurea and lost on average1.3 kg (5.8 to 3.2 kg) on metformin (p<0.001). Eleven RCTs evaluated comparative effects on glycemic control by subjects baseline hemoglobin A1c (HbA1c) level, and found a greater absolute reduction in HbA1c among those with higher baseline HbA1c. Two studies examined all-cause mortality in patients with baseline heart disease. One study of patients with congestive heart failure reported decreased all-cause mortality risk in patients taking metformin compared with sulfonylurea (adjusted HR 0.70 [0.54-0.91]) at a median follow up of 2.1 years. The second study found increased all-cause mortality in patients with ischemic heart disease taking metformin compared with sulfonylurea or repaglinide (adjusted HR3.82 [1.22-11.9; p=0.02]).

CONCLUSION: Effectiveness and safety of oral diabetes medications may depend on patient sex, pre-treatment HbA1c level, and the presence of heart disease. Overall, strength of evidence was low because studies were not powered to assess differences within or between sub-populations. Future research is needed to address medication effects in patients with co-morbid conditions.

PATIENT REPORTED BARRIERS TO ENROLLMENT IN A PATIENT PORTAL Mita Sanghavi Goel 1; Tiffany Brown 1; Adam Williams 1; Romana Hasnain-Wynia 1; Andrew Cooper 1; Jason Thompson 1; David Baker1. 1Northwestern University, Chicago, Illinois . (Tracking ID # 11196)

BACKGROUND: With the introduction of meaningful use criteria and the advancement of electronic health records (EHRs) generally, use of tethered personal health records, or patient portals, is becoming more commonplace. Previous studies have found low rates of enrollment in patient portals overall and significant disparities in enrollment by race and ethnicity, but the reasons for these findings are not well understood. Our study aims to identify patient-reported barriers to enrollment in a patient portal.

METHODS: Patients were eligible if they had an attending physician within the General Internal Medicine (GIM) clinic, two face-to-face visits in the past 18 months, and an order placed by their physician to activate the electronic patient portal, but did not enroll within 30 days of the order being placed. After generating lists of eligible patients, we randomly selected patients for the telephone survey. Lists were stratified by race as recorded within the EHR to ensure adequate sampling of non-white patients. Patients who were contacted and agreed to participate completed a 15 minute survey that used closed and open-ended questions to examine: (1)

whether participants recalled a discussion with their provider about the patient portal (2) whether participants attempted enrolling in the patient portal (3) experiences of those attempting to enroll (4) reasons for not attempting to enroll (5) access to and typical use patterns of the internet and (6) perceptions of benefits of the patient portal. We used content analysis to categorize responses to open-ended questions. Analyses were performed in SAS. Racial differences in responses were analyzed using Fishers exact test for categorical variables; $p<0.05$ was considered significant.

RESULTS: The survey response rate was 61%. Participants mean age was 51 years; 72% were female, 70% had a college degree or greater, 48% were black.

Reasons for not enrolling in the patient portal. Twenty-six percent of respondents did not remember discussing the patient portal with their providers, 63% did not attempt to enroll despite remembering a discussion with their providers, and 11% attempted to enroll, but did not succeed. Differences by race were not significant.

Reasons for not attempting to enroll. Among those who did not attempt to enroll in the patient portal, 60% endorsed reasons related to low priority or inattention as the primary reason for not attempting to enroll, 30% reported attitudinal barriers and 8% reported technical barriers. Differences by race were not significant.

When asked whether specific factors contributed to not attempting to enroll, black respondents were significantly less likely than whites to report that they forgot (52% vs. 74%, $p<0.05$) or were too busy to enroll (30% vs. 59%, $p<0.05$). There were no significant differences in access to the internet as a reason for not attempting to enroll.

Attitudes towards patient portals. Overall, respondents favorably viewed a variety of benefits that patient portals provide; however, black respondents were less likely than whites to endorse as important or very important features that assisted self-management: getting test results (69% vs. 86%, $p<0.05$), managing medical problems (58% vs. 82%, $p<0.05$) and seeing when you are due for screening tests (72% vs. 88%, $p<0.05$). There were no significant differences in attitudes towards administrative tasks such as scheduling appointments or refilling medications.

CONCLUSION: Strategies to increase uptake of the patient portal need to ensure patients understand the features of a patient portal, remember being invited to enroll, and receive follow-up reminders to enroll. In addition, interventions to eliminate racial disparities in patient portal enrollment must address attitudinal barriers and not focus solely on improving access.

SCREENING, BRIEF INTERVENTION AND REFERRAL TO TREATMENT (SBIRT) FOR OPIOID ABUSE IN AN URBAN HOSPITALIZED POPULATION: A PILOT STUDY Richard Gil 1; Nancy L Sohler 2; Mia Brisbane 1; Gabriela Ordonez Llanos 3; Chinazo O Cunningham4.

1Montefiore Medical Center, Bronx, New York ; 2The City College of New York, NY, New York ; 3Foundation Minga, Bronx, New York ;

4Albert Einstein College of Medicine, Bronx, New York . (Tracking ID # 11197)

BACKGROUND: BACKGROUND: Numerous studies demonstrate the deleterious health outcomes associated with substance abuse and dependence. To intervene early in the course of substance use, Screening, Brief Intervention, and Referral to Treatment (SBIRT) has been advocated by many. In primary care settings and emergency departments, SBIRT has been successful in screening for and identifying populations with problematic alcohol use, providing brief interventions to them and referring them for treatment, leading to improved outcomes. Although substance use disorders are common among hospitalized patients, few studies have examined the feasibility of or outcomes associated with conducting SBIRT in hospitalized patients. Although data regarding SBIRT for drug use has been sparse, with the rise in opioid use, abuse, and dependence, many

advocate for SBIRT specifically for drug use. We sought to test the feasibility of conducting SBIRT for problematic opioid use targeting patients hospitalized on the medical wards of a large urban academic medical center.
METHODS: METHODS: On 22 days between October 2009 and 2010, we identified all adult patients who were admitted within 24 hours to four different floors of the medical wards of a large urban academic medical center in the Bronx. A research assistant attempted to reach all admitted patients who were 1875 years old, fluent in English or Spanish, and alert and oriented. Patients who were intubated, restrained, or on contact isolation were excluded. We administered audio computer-assisted self-interviews (ACASI) to patients, collecting sociodemographic information and risk of problematic opioid use (using the Alcohol, Smoking, Substance Involvement Screening Test [ASSIST] questionnaire, developed by the World Health Organization [WHO]). According to the WHO criteria, patients were categorized as having no opioid use, or low, moderate, or high risk of problematic opioid use. Those who had moderate or high risk problematic opioid use received a brief computer-based intervention in which they were informed about their risk and opioid addiction treatment options, and invited to receive additional information and referrals to treatment. We conducted simple frequencies to describe patients sociodemo-graphic and clinical characteristics.
RESULTS: RESULTS: Of the 231 patients who were newly admitted to the medical wards, we were unable to reach 42 (18.2%) (they were already discharged, not in their rooms, or otherwise occupied with health care providers) and 42 (18.2%) refused to participate. Of the remaining 147 patients, 61 (41.5%) were ineligible for the following reasons: age >75 years (n=37), on contact isolation (n=12), disoriented (n=8), in severe pain (n=2), blind (n=1), and not fluent in English or Spanish (n=1). In addition, computer issues resulted in incomplete interviews in 3 patients. Of the 75 patients included in this analysis, the mean age was 48.6 years, and the majority were women (65.3%), Hispanic (49.3%) or black (38.7%), had a high school education (68.0%), and had public insurance (66.7%). In terms of opioid use in the prior 3 months, 42 (56.0%) reported no opioid use, 4 (5.3%) low risk, 26 (34.7%) moderate risk, and 3 (4.0%) high risk of problematic opioid use. Of the 29 patients with moderate or high risk, 19 (65.5%) were interested in referral to treatment and 27 (93.1%) reported that the brief computerized intervention was useful.
CONCLUSIONS: In a large urban academic medical center, we found moderate or high risk of problematic opioid use in 39% of patients hospitalized on the medical wards. Our data suggest that in the inpatient medical setting, ample opportunity exists to identify patients with problematic opioid use, to provide a brief intervention, and to refer them to treatment. In fact, of those with moderate or high risk of problematic opioid use, over half were interested in referral to treatment, and nearly all reported usefulness of the brief intervention. Despite this, we question whether a model of conducting SBIRT like ourswith a dedicated person outside of the team delivering health careis feasible. Of all patients newly admitted to the hospital, only one-third were screened for problematic opioid use, as approximately one-fifth were unable to be contacted, one-fifth refused to be screened, and one-fourth were ineligible. Because moderate or high risk of problematic opioid use appears to be common in hospitalized patients on medical wards and has substantial consequences, further research examining SBIRT related to problematic opioid use in hospitalized patients is warranted.
UNDERSTANDING PROVIDER PERSPECTIVES ON CARE TRANSITIONS FROM HOSPITAL TO HOME: FINDINGS FROM A 360 DEGREE QUALITATIVE EVALUATION Honora Englander 1; Melinda Davis 1; Devan Kansagara2. 1Oregon Health &Science University, Portland, Oregon ; 2Portland VA Medical Center, Portland, Oregon . (Tracking ID # 11201)
BACKGROUND: Patients are vulnerable to experiencing poor quality, fragmented care as they transition from acute hospital care to home. Transitional care improvements are a growing priority for health reform and are an opportunity to accomplish the triple aim of lowering health care costs, improving quality, and increasing patient satisfaction. Understanding gaps in care and barriers to improvement from both patient and provider perspectives informs the development of transitional care interventions. Prior qualitative work has found that

patients and their caregivers feel poorly prepared for self-care after discharge. Few studies, however, have examined transitional care deficiencies from a health care provider perspective. We conducted a qualitative assessment to evaluate multidisciplinary inpatient and outpatient provider perspectives of roles, barriers, and facilitators to effective care transitions from hospital to community-based care.
METHODS: Investigators conducted in-depth semi-structured interviews (2) and focus groups (13) from October 2010 to January 2011. Participants were drawn from the general medicine and cardiology services at an urban, academic hospital; three partnering outpatient primary care clinics; and one Medicaid managed care plan. Standard qualitative analytic techniques were applied to verbatim written transcripts.
RESULTS: The seventy-five participants included internal medicine residents (6), inpatient hospital attendings (5), outpatient general medicine attendings (5), subspecialty attendings (4), community clinic providers (9), pharmacists (8), nurses (14), case managers (8), social workers (1), and hospital executives (15). The following themes emerged as key contributors to poor transitions of care: 1) lack of clarity of roles and responsibilities among providers and across settings, 2) lack of multidisciplinary communication, and 3) patient barriers such as no insurance, lacking a usual source of care, substance abuse, and complex medication regimens. Many providers noted the irrationality of providing high cost rescue hospital care for the uninsured without adequate transitional care. Providers also noted that the uncertainties associated with unsatisfactory transitions negatively impact job satisfaction. Finally, providers noted opportunities to expand education and competencies in care coordination across disciplines and facilities.
CONCLUSION: Many providers from a range of disciplines are involved in transitions of care across settings. Providers experiences underscore that communication across settings and, importantly, across disciplines may be critical to enhancing care transitions. Clarity about roles and responsibilities as well as education that promotes collaboration is likely to improve transitional care. In addition, barriers unique to specific patient populations such as the uninsured are particularly challenging and may be an additional opportunity for focused care transitions improvements.
PREDICTING 30 DAY READMISSIONS WITH ADMINISTRATIVE DATA John W. Showalter 1; Nicole Swallow 1; Colleen Rafferty1. 1Penn State University, Hershey, Pennsylvania . (Tracking ID # 11203)
BACKGROUND: Readmissions within 30 days of hospital discharge have been shown to be frequent and costly. Published studies that have successfully reduced 30 day readmissions involve time and

labor intensive interventions; many institutions may not have adequate resources to apply similar interventions to all admitted patients. Development of a risk assessment tool that identifies patients at highest risk of readmission could help institutions to focus interventions on the highest risk patients. Previously published risk assessment tools are limited because their use requires direct patient contact, large amounts of clinical data, and they cannot be done at the time of admission. The objective of this study is to create a risk assessment tool for 30 day readmissions which uses easily obtainable administrative data, requires no patient contact, can be done at the time of admission, and performs better than published risk assessment tools.
METHODS: An expert system (rule based computer learning program) was created using data from all adult patients discharged from the Penn State Hershey Medical Center Internal Medicine service between November 1, 2008 and October 31, 2009. The expert system was developed from subjects randomly assigned to a training data set and was validated against the remaining subjects (testing data set). The expert system was then further validated against an independent data set that included all patients discharged from the Internal Medicine service between November 1, 2009 and October 31, 2010. The primary outcome was all-cause 30 day readmissions to any service at our institution and the secondary outcome was all-cause 30 day readmissions to the Internal Medicine service. Four input variables were used to develop the expert system: 1. number of diagnoses billed, 2. presence of an outpatient clinic visit, 3. presence of an inpatient admission and 4. presence of an Emergency Department visit. All were restricted to the year prior to the date of inpatient

admission and to data from our institution.
The decision making process of the expert system was based on certainty factor analysis. Certainty factor analysis refers to a mathematical method of handling uncertainty, originally designed for medical decision making. Using the training data set, certainty factors for utilization were determined by calculating the readmission rates for the eight unique patterns of utilizing outpatient, inpatient and Emergency Department services. Certainty factors for number of diagnoses billed were determined for subjects with zero, 110 and greater than 10 diagnoses billed, also based on the training data set. A composite certainty factor for readmission (CFR) was then calculated based on those numbers for all subjects. Threshold values of CFR to predict subjects with a high risk of readmission were calculated using receiver operator characteristic (ROC) curve analysis.
RESULTS: The total study population consisted of 5,191 subjects with 1,244 in the training, 1,244 in the testing and 2,743 in the independent validation set. There was no statistical difference between the three data sets with regard to age, sex or race. The independent validation set had a significantly (p-value <0.01) increased rate of readmissions (14.8%) as compared to the training(12.8%) and testing (11.8%) sets.
Using a threshold CFR value of 0.352 the system was able to identify patients at high risk for readmission. Readmission rates for patients with a CFR above the threshold value were greater than 30 percent for all data sets. In the independent validation set, 9.8 percent of patients were above the threshold. This high risk group accounted for27.1 percent of readmissions to the Internal Medicine service. Additionally, subjects in the independent validation set with a CFR below 0.2 had a readmission rate to the Internal Medicine service of only 5.4 percent. CONCLUSION: Using only administrative data which is readily available at the time of admission, our expert system was able to identify a group of patients who had a greater than 30 percent chance of readmission. The size of the group identified, 9.8% of the total population, is almost twice as large as other published clinical
risk assessment tools. Identifying this high risk group early in their clinical course allows them to be the focus of interventions shown to be effective, and may result in an even larger reduction in read-missions than previously observed. Further study of this expert system will include adapting it for use at other institutions and validating it within their patient populations.
HIV SCREENING PRACTICES IN AN URBAN OUTPATIENT RESIDENT CLINIC Michelle Doll 1; Lawrence Ward 2; Robert Bettiker 2; Rafik Samuel2. 1Temple University Hospital, Philadelphia, Pennsylvania ; 2Temple University School of Medicine, Philadelphia, Pennsylvania . (Tracking ID # 11204)
BACKGROUND: Routine HIV testing for all patients has been advocated by the CDC since 2006. However, many patients continue to receive HIV diagnoses late in the course of the disease. Late diagnoses have devastating consequences both for public health and for the health of the individual. We reviewed the HIV screening practice of internal medicine residents in our outpatient clinic. We also surveyed physicians and patients to determine acceptability of screening.
METHODS: A retrospective chart review was conducted of 205 patients. Eligible patient charts contained at least 2 office visits and a visit within the last year. Data collected included age, sex, race, comorbidities, and HIV risk factors. A separate data collection was performed using surveys, which were given to clinic patients, resident physicians, and attending physicians. The patient surveys included a self-risk assessment, degree of willingness to be tested, reasons for declining testing, and history of prior screenings. The physician surveys included a self-assessment of success in HIV screening efforts, ranking of priority of HIV screening compared with other primary care issues, identification of barriers to screening efforts, and comfort level in performing HIV counseling.
RESULTS: HIV screening was offered to 38% (79) of our patients and 35% (71) went on to complete the testing and have a documented result. One patient was HIV positive, while the other 70 tested were non-reactive. 28 resident physicians and 8 attending physicians completed surveys. Residents estimated that they were

screening 49% of their patients for HIV, while attending physicians estimated 42%. 64% of physicians said they would screen more people if rapid testing were available in their clinic. Time constraints and competing health issues were cited as the biggest barriers to screening by physicians in our study. Our clinic population does have a high prevalence of chronic medical conditions, with an average of 5 problems per patient requiring ongoing medical care. There was also a high prevalence of HIV risk factors. Alarmingly, in the subset of patients not offered testing for HIV, 29% had the presence of a risk factor such as past or present drug and alcohol abuse, high risk sexual practices, or history of hepatitis or STDs. Patient surveys were completed by 29 individuals. The vast majority of patients surveyed believed themselves to be very low or no possible HIV risk. However, most patients were still agreeable to HIV testing with the only 4 out of 29 indicating that they would decline testing. Those four all cited no possible risk as the reason to decline testing.
CONCLUSION: While there is an overall positive patient perception of HIV testing, we are falling far short of CDC recommendations. Perhaps most concerning is the lost opportunities for HIV testing in patients with clear risk factors. Since time constraints and competing health issues are cited as significant barriers to HIV screening efforts by physicians, tools for quick and concise counseling regarding testing may be of benefit. In addition, ongoing physician education may help us to prioritize HIV testing.

STUDENTS PROGRESSIVE MASTERY OF COMMUNICATION SKILLS OVER THE FIRST YEAR OF MEDICAL SCHOOL Kathleen Hanley 1;
Sondra Zabar 2; Adina Kalet 3; Nina Yeboah 1; Colleen C. Gillespie1.
1NYU School of Medicine, New York, New York ; 2NYU School of Medicine, New York, New York ; 3NYU School of Medicine, Brooklyn, New York . (Tracking ID # 11205)
BACKGROUND: Students enter medical school with diverse backgrounds and skill sets and can be expected to respond in different ways to education and training. Recognizing this, medical education curricula in the 21st century should be designed to identify students strengths and weaknesses and to be sensitive to specific patterns of development over time. We designed and implemented a baseline and end-of-first year assessment of medical students communication skills in order to better understand students communication skills development.
METHODS: Within the first 2 weeks of matriculation, incoming medical students (n=165) participated in a 3-station Standardized Patient (SP) Examination. SPs assessed communication skills in 3 broad domains (information gathering, relationship development, and patient education and counseling; Cronbachs alphas>.82) using a validated, behaviorally anchored checklist with a 3-point response scale (not done, partly done, well done). Scores were calculated as % items well done. At the end of students first year of medical school, as part of their Practice of Medicine course, students completed another 3-station SP examination using the same communication skills checklist. Changes in students communication scores from the beginning to the end of their first year of medical school are described using paired t-tests and the degree to which individual students relative communication skills standing (>1 SD below their class mean, +/1 SD of the mean, >1 SD above their class mean) changed over time is also explored.
RESULTS: Mean communication scores (% well done) for incoming medical students were as follows: overall communication=57.2% well done, SD 15.5%; information gathering=62.2%, SD15.6%; relationship development=61.4%, SD 18.3%; patient education and counseling=42.9%, SD 20.4%. By the end of the year, mean change in scores (on different albeit similar cases) was as follows: communication score mean=+10.5%, SD 18.6, p<.001;information gathering mean=+7.6%, SD 20.4, p<.001; patient education and counseling mean=+27.0%, SD 22.6%, p<.001. Relationship development mean improvement=+3.8%, SD 25.2%, p=.054. Overall, for 56% of the students, their relative standing stayed the same between assessment time points; 23%

of students saw their relative standing decrease over time; and 20% of students saw their relative standing increase over time. 68% (n=21) of the 31 students who scored >1 SD below the mean at baseline improved in their relative standing at the end of the year (scoring within 1 SD of the mean or more than 1 SD above the mean), and their overall communication score increased, on average, by 37%(SD 10%). 74% (n=20) of the 27 students who scored >1 SD above the mean at baseline saw their relative standing decrease at the end of the year (scoring within 1 SD of the mean or >1 SD below the mean), experiencing a mean decrease in scores of 11%, SD12%.
CONCLUSION: Medical students overall communication abilities, as assessed by SPs in 3-station OSCEs, appear to increase during their first year of medical school. The largest increases were seen in their patient education and counseling, a skill set that was lower
than the other communication skills at baseline and one to which the curriculum devotes substantial time. Aggregate changes however, can mask important individual level changes: while most students relative standing didnt change over time, most high-scoring students saw their relative standing decrease slightly probably largely due to ceiling effects and regression to the mean, and the majority of low-scoring students saw their relative standing increase fairly dramatically across all 3 domains. Each of these patterns has different implications for assessing and evaluating student mastery of core clinical skills and more importantly for tailoring education and remediation. Following this cohort of students throughout their education will help us better understand how to develop and enhance the communication skills students bring to us.
SICKLE CELL PATIENTS CARE IN THE EMERGENCY DEPARTMENT Allison E. Jordan 1; Cory R. Walker 1; Kit N. Simpson 1; Cheryl P. Lynch1.
1Medical University of South Carolina, Charleston, South Carolina . (Tracking ID # 11206)
BACKGROUND: One in 500 African-American children has sickle cell disease (SCD), and is managed in pediatric clinic settings. In the late adolescence to young adult phase, patients with SCD face a difficult transition from pediatric to adult care. Consequently, frequent visits to the emergency department (ED) serve as their regular source of care. Many patients with SCD are often perceived as drug seeking because they require high levels of narcotics to manage their pain, especially during sickle cell pain crises. Patients greater than 20 years old with frequent painful events have the greatest risk of early death, indicating that continuity of care is important to minimize morbidity and mortality. Currently, there is no consistent widespread comparable practice among SCD patient providers to assess neither efficacy of treatment nor for consistent experience of patients. The Medical University of South Carolina (MUSC) ED treats approximately 1,400 adult SCD patients per year. The purpose of the study was to determine processes of care among SCD patients presenting to the adult ED for pain crisis.
METHODS: Of 576 ED visits between November 2008 and March 2009, a retrospective review was performed of 10 randomly selected patient electronic medical charts. Since patients with SCD had more than one ED visit during the specified time period, there was a greater likelihood of selecting frequent ED users. However, no duplicate charts were reviewed; each visit was taken as a separate event. Demographic, clinical and utilization data (vital signs including pain rating, processes of care, and medication) were abstracted with special attention to nursing documentation.
RESULTS: The selected patients were 70% female with mean age of 29 years (range 1951). Mean pain score on admission was 9.3 (range 710). Home pain medication was recorded for 80%, but only 40% of these records had the doses recorded. Fifty percent of patients had a primary care physician (PCP) recorded.
Table 1. Treatment Processes During Emergency Department Visit Table 2. Return Visits to Emergency DepartmentSouth Carolina state discharge data shows that each ED visit costs $1200 and 58% of patients with SCD are Medicaid recipients. In 2007, South Carolina hospitals had 2,772 admissions for sickle cell pain crisis

with total charges of $58 million and an estimated $18.6 million for South Carolina hospitals.

CONCLUSION: Adult SCD patients use of the ED poses both quality of care and economic issues. To facilitate the transition of pediatric sickle cell patients to adult care, a medical home model should be used to introduce patients to their new PCPs, case managers, and nurses. Sickle cell pain crisis protocols must be implemented, and better documentation of a patients home medications is needed to adequately treat their pain in the ED.

INAPPROPRIATE DISPENSING OF ELECTRONICALLY DISCONTINUED MEDICATIONS: AN EMERGING PATIENT SAFETY CONCERN Adrienne Allen 1; Thomas Sequist2. 1Brigham and Womens Hospital, Boston, Massachusetts ; 2Brigham and Womens Hospital, Newton, Massachusetts. (Tracking ID # 11207)

BACKGROUND: Electronic medication prescribing is greatly facilitated by the adoption of electronic health records with direct links to pharmacies to initiate prescriptions. These systems do not support the transmission of medication discontinuation orders from the electronic record to the pharmacy, creating the potential for inappropriate dispensing of previously ordered medications.

METHODS: We used electronic data within a large multi-site group practice using a common electronic health record to identify adult patients (>18 years) with an electronically discontinued anti-hypertensive or statin medication during a 12 month period during 2008 to 2009. Pharmacy dispensing records were reviewed to determine if these medications were dispensed in the 12 months following the discontinuation order. Patient demographic and clinical data were obtained from the electronic health record. We fit hierarchical multivariable logistic regression models to identify predictors of dispensing discontinued medications after adjusting for patient sociodemographic characteristics (age, sex, race and insurance status), total number of prescribed medications, and presence of comorbid conditions (diabetes, hypertension, and cardiovascular disease).

RESULTS: We identified 63,615 patients who had 140,245 anti-hypertensive medications and statins discontinued during the study period. 2,565 (1.8%) of these medications were dispensed to 1297 (2%) patients following electronic discontinuation within the electronic health record, including 2% of anti-hypertensive medications and 1.3% of statins. The vast majority (93%) of these medications were dispensed at least 1 day after the medication was discontinued, with 7% being dispensed on the day of the discontinuation order. Among the 2,565 inappropriately dispensed medications, 44% were refilled more than once during the 12 months following the discontinuation order, with an average of2.0 erroneous refills per medication during this time. Patients with more than 5 medications on the electronic medication list, statin discontinuation, non-white race, and Medicaid insurance were more likely to have had a discontinued medication dispensed by the pharmacy (Table).

CONCLUSION: Dispensing of discontinued medications does occur and poses an important risk to patient safety, particularly among those patients receiving multiple prescription medications. Further work should evaluate patient harm from this dispensing and explore methods to improve communication between physician offices and pharmacies.

THE COURTEOUS CONSULT: RESIDENT REFLECTIONS ON INPATIENT CONSULTATIONS Lauren Peccoralo 1; Anna Podolsky 1; Katherine Krauskopf 1; Kristofer L Smith 1; David Stern1. 1Mount Sinai School of Medicine, New York, New York . (Tracking ID # 11210)
BACKGROUND: The quality of clinical consultations varies for physician trainees in academic centers. Prior work demonstrates that poor quality consult interactions can lead to lower quality of care, decreased patient satisfaction and an unprofessional work environment. Little is known about barriers to consult quality in the physician trainee setting. We explored trainees perceptions of consultation interactions on the inpatient wards 1) to generate hypotheses about elements of and barriers to high-quality, professional consults and 2) to develop a quantitative study and an educational intervention to improve the consistency, quality and courtesy of consult interactions. METHODS: We conducted our qualitative study in one urban academic medical center. Participants were internal medicine (IM) residents in their second and third post graduate years (PGYs). Investigators developed a moderator script to guide the one hour-long semi-structured focus group. During the session, the moderator asked trainees to discuss perceptions about positive and negative consult interactions, elements of a good consult and downstream effects of consult interactions. The focus group was audio recorded and transcribed verbatim. Investigators used a grounded theory approach with inductive-deductive code generation for data analysis. Two investigators independently coded the transcript. Investigators decided on final codes, categories and themes via consensus.
RESULTS: The focus group consisted of eight IM residents, half in their second PGY and half in their third PGY. Five of the participants were female and all had functioned in both the roles of a consulter and

consultant during their training. Three main themes emerged from this focus group data: mutual respect, the consult as a teaching tool, and the value of verbal communication. Regarding mutual respect between a consulter and a consultant, important elements discussed were consulter preparedness, transparency regarding consult purpose and application of recommendations. Within the theme of consult as a teaching tool residents identified three categories of teaching: teaching to prepare for a consult, patient-based teaching and direct clinical skills teaching. Finally, the importance of regular and high quality verbal communication between the consultant and the primary team was evident in its effect on coordination of care, clarity of the care plan, patient satisfaction and collegiality among multispecialty trainees. CONCLUSION: IM Residents in our focus group believe that mutual respect, teaching and verbal communication are key components of a successful and professional consult. These findings have important implications in a changing hospital work environment. With emerging electronic medical records in many academic centers, ever tightening work hour restrictions for trainees and increasing clinical volume demands, the need for verbal communication and time for teaching will likely decrease, jeopardizing the quality of consult interactions. The identification of these themes along with the evolving practice environment provide important directions for continued qualitative and quantitative investigation and interventions aimed at improving the consultation process among physician trainees.
SMOKING CESSATION-RELATED INFORMATION, MOTIVATION, AND BEHAVIORAL SKILLS SPECIFIC TO HIV-INFECTED SMOKERS James Sosman 1; Laura Thibodeau 1; Nasia Safdar 1; Doug Jorenby 1; Sheryl

Catz 2; Ben Balderson 5; Jennifer McClure 5; K. Rivet Amico3.
1University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin ; 2Group Health Center for Health Studies, Seattle, Washington ; 3University of Connecticut, Hartford, Connecticut . (Tracking ID # 11212)
BACKGROUND: The intersection of the tobacco and HIV/AIDS epidemics represents an area of growing clinical and public health importance. Until recently, cigarette smoking among HIV + persons received little attention because of limited life expectancy. Effective antiviral treatments have resulted in dramatically increased life expectancies. In the U.S., the prevalence of cigarette smoking is estimated to be 50-70% among HIV + persons vs. 20.8% in the general population. Smoking is associated with reduced quality of life, increased incidence of bacterial pneumonia, risk of malignancies, and increased mortality compared to HIV + non-smokers. We hypothesize that many people are unaware of the ways in which HIV and tobacco use may interact, and some may have low motivation or lack skills relevant to smoking cessation.
METHODS: We recruited a cross sectional convenience sample of HIV + adult smokers from two HIV clinics to participate in structured quantitative interviews. The interview included an HIV specific measure of smoking-related information, motivation, and behavioral skills and standard measures of current smoking behavior, smoking history, self-efficacy for quitting smoking, knowledge of smoking consequences, and demographic and psychosocial characteristics. Participant medical records were abstracted for year of HIV/AIDS diagnosis, HIV viral load, CD4 lymphocyte count, and antiretroviral medication use (HAART). Descriptive statistics were computed for all study variables.
RESULTS: Of eligible smokers approached, 70% (61) consented and 58 completed the interview. Most were men (77%), 81% were Caucasian, median age 46 years and were HIV + for 9 years. Most were on HAART (79%) with a median CD4 count 473 cells/ul and 65% had undetectable HIV viral loads. Participants had on average initiated smoking at age 17 and smoked for 25 years. Fifty-five percent indicated that their HIV diagnosis had no effect on their smoking, while 32% reported that their HIV diagnosis had increased their smoking. Sixty-seven percent reported that they were seriously considering quitting smoking in the next 6 months, and 28% were considering quitting in the next 30 days. The mean time that smokers had quit was 12 months. Fifty-eight percent had not used any cessation medication/aides in the past. Thirty-eight percent did not know how smoking affects the course of HIV disease; however, 91% thought they understood smoking risks for HIV-negative people. Seventy-five percent thought smoking is a way to relax, and 44% thought smoking is a good way to cope with feeling down or stressed. Primary motivations included: 81% worried that smoking may have long term negative effects on their health; 89% were ready to make positive changes in life to improve their health; 73% believed that family and friends think they should quit smoking. Self-efficacy for cessation skills was low: 37% felt confident that they could quit smoking; 64% thought it would be hard or very hard to go through a normal daily routine without a cigarette. However 49% accepted the telephone number for the Tobacco Quit Line when offered at the end of the interview. Seventy-one percent reported alcohol use with median AUDIT-C score of 6 (range 110); 58% thought it would be hard or very hard to drink alcohol without smoking.
